LIGHT-HOUSE.

LIGHT-HOUSE, in the *Marine*, is a building or watch-tower erected upon the sea-shore, to serve as a landmark to mariners in the night, to avoid any rocks or other dangers. The light-house is generally a high tower, having at the top an apartment called the lantern, with windows on all sides, to exhibit the light made within it by the flame of an open fire, or by lamps or candles. It is frequently of service to navigation, to erect light-houses upon insulated rocks rising from the sea, to warn ships of their approach to such rocks. Of this kind are the Eddystone rocks off Plymouth, and the Bell rock at the mouth of the Forth in Scotland. In these situations, the heavy swell of the sea, when agitated by a storm, strikes with such force against the building, as to require every precaution to secure them from being overthrown by the continued action of so powerful an enemy. The Eddystone rocks being the most celebrated, as well from their peculiarly exposed situation, as from the great ingenuity displayed in the construction of the light-houses erected at different periods upon them, renders them deserving of particular description. The history of the different erections has been already given under the head of EDDYSTONE. We here intend describing the construction of each, which will be a summary of all the different kinds of light-houses of wood or stone.

Mr. Winstanley's light-house was begun upon the Eddystone rock in 1696, and was more than four years in the erection, from the many interruptions of the wind, which from some quarters causes the sea to break over these rocks with such violence, as to prevent the possibility of landing upon them, though the sea around is very quiet. This is occasioned by the rocks being open to the swell from the Great Atlantic ocean, or from the Bay of Biscay, in all the south-western points of the compass; and is increased by the form and position of the rocks, which have

a regular slope to the south-west from the deep sea to the rock upon which the house is erected, and which, therefore, receives the uncontrouled fury of these seas, meeting no other object to break upon, and the effect of so great an extent of water, caused by the hard S.W. winds, continues for many days, though succeeded by a calm, and breaks frightfully upon Eddystone. When there is no wind, and the surface of the sea appears smooth, Mr. Winstanley's light-house appears, from an engraved plate of it, published by himself, to have been a stone tower with 12 sides, rising 44 feet above the highest point of the rock, which is inclined so as to be 10 feet lower on the opposite side of the house. The tower was 24 feet in diameter. At the top were a balustrade and platform: upon this eight pillars were erected, and supported a dome of the same diameter as the tower. From the top of this arose a smaller octagonal tower, 15 feet in diameter and seven in height; and upon this was the lantern 10 feet in diameter, and 12 high, containing the lights. It had a gallery or balcony surrounding it, to give access to the outside of the windows. The whole was surmounted by a fanciful iron work with a vane. The entry was by a door at the bottom, which was solid stone, except the aperture for the staircase, 12 feet in height. Above this were three floors, the lowest being the store-room, the next the flate-room, and the third the kitchen. These occupied the height up to the level of the platform, or open gallery above-mentioned. The dome above this contained the lodging-room, and the octagon above it the attending or look-out room, immediately beneath the lantern. This edifice was, as before-mentioned, more than four years in erecting. The first summer (for it is only in this season the rock is accessible) was spent in making 12 holes in the rock, and fastening 12 great irons to hold the future work. In the second year, a solid pillar 14 feet diameter, and 12 feet high,

B

LIGHT-HOUSE.

high, was built as a core or centre for the building. The third year the pillar was increased to 16 feet diameter, and all the work was raised, which to the vane was at that time 80 feet. The workmen lodged in the house soon after Midsummer, but were by bad weather imprisoned 11 days before a boat could relieve them. A light was exhibited on the 14th of Nov. 1668. But finding that the sea frequently broke over the lantern, in the fourth year the whole building was encompassed with a new work of four feet in thickness, made solid for near 20 feet high, and the lantern was raised 40 feet higher than at first, making it 90 feet to the top of the cupola of the lantern, above which the vane rose 22 feet. "Yet after all," Mr. Winstanley says, "the sea in storms lies in appearance 100 feet above the vane, and at times doth cover half the side of the house and the lantern, as if it were under water." The joints of the additional stone work of the fourth year, appear to have been covered with an iron or copper hoop encompassing the building, to prevent the sea washing out the mortar. The building withstood the wrath of the sea only till the year 1713, when the inventor, being at Plymouth to superintend some repairs of the building, went off to it on some of his friends intimating the danger of the building, from a storm which seemed coming on. He expressed a wish that he might be present in the most violent storm which ever blew, to observe its effect on the structure. In this he was too amply gratified, for on the 26th of November a violent storm arose, and the next morning no vestige of the light-house remained, except some of the irons which were fastened in the rock, and a piece of iron chain, which was jerked fast into a cleft of the rock, and nothing was ever afterwards found. Thus perished the first light-house with its ingenious, but unfortunate, builder. A West Indian ship was lost on the rocks soon after the light-house was overthrown. This circumstance, and the great utility of the light while exhibited, stimulated the Board of Trinity house, who had the management of the building, to erect another, and an act of parliament, of the 4th of queen Anne, was passed in 1706, to enable the Board of Trinity house to raise duties on ships to rebuild it, of which they granted a lease of 99 years to Capt. Lovel, as he engaged to build and maintain the house. In July 1706, the work was begun under the direction of Mr. John Rudyerd, who was at that time a silk mercer on Ludgate hill, London, but who appears to have possessed much ingenuity and mental resource. He, like Mr. Winstanley, published a print drawn by B. Lewis, and engraved by J. Stuart, which informs us, that it was a conical frustum of wood, formed of 71 upright beams, united together by being belted to circular kirbs of wood with staves, upon which kirbs the floors were framed. It, in some degree, resembled an immense conical cake, but with a loop: the diameter at the base was 23 feet, at the top 15 feet, and its altitude, from the highest point of the rock to the top of the upright, was 62 feet. At the top of the building was a balcony, surrounded by a railing, and in the centre of the area thus formed the lantern was situated. It had windows on all sides, and was of an octagonal figure, 12 feet in diameter, and 13 high, surmounted by a cone with a double ball at top, instead of the fanciful iron work which characterised the first edifice. Mr. Rudyerd, from principles totally different from those of his predecessor, made his building quite plain, without the least projection or ornament on which the water could act when dashing against it; and he omitted no precaution of uniting all the parts together, and fastening the whole to the rock. As the surface of the rock was naturally inclined, and the whole building would have had a tendency to slide down it, if merely placed upon it, as Mr. Winstanley's was, Mr. Rudyerd wished to

reduce its surface into level steps, upon which each timber would have a horizontal bearing; but finding this to be the most difficult of the whole undertaking, it was imperfectly executed, only five steps being cut, and those did not take out all the inclined surface; however, it was sufficient for the purpose.

The building was filled up quite solid for 19 feet from the lowest point of the rock, and, excepting the well for the stair-case, was solid to the height of 37 feet. The solid was formed of three beds of masonry, with strong floorings of timbers between each bed, to unite them with the external uprights. The lower bed contained five courses of stone, and was five feet thick; the second was the same, and the third was four feet thick, containing four courses. The whole erection, in addition to the weight of the stone, which was about 250 tons, was secured to the rock by 36 iron cramps, part of them arranged in a circle about a foot within the external uprights, and the remainder, which were smaller cramps, in an interior circle three feet distant from the former, to hold down the floors of timber which had the stone beds between them. In the centre of the building a strong mast was erected, secured by two cramps to the rock at the bottom, and rising above the solid to the height of 48 feet, being united to the framing of each floor it passed through, and thus forming a central axis to strengthen the whole. The rock above the solid contained four apartments, the lower being the store room, the next the slate room, the third the bed chamber, and the fourth the kitchen, immediately beneath the lantern. In the manner of fixing the irons to the rock, upon the duration of which the security of the whole work depended, Mr. Rudyerd succeeded most admirably. The holes in the rock were made by drilling two holes rather diverging from each other, so that they would be an inch more asunder at 15 or 16 inches depth, than on the surface of the rock. A third hole being drilled between these two, and the three being broken into one, formed a hole larger at the bottom than the top. The iron cramp was formed of two pieces, which, when laid together, were of the shape of the hole, but when separated, one was larger at the bottom than the top, and the other smallest at the bottom; therefore the former being first put down into the hole, and the latter driven in by the side of it, wedged it fast, and both being united by the same bolts which attached them to the timbers, rendered it impossible to draw them out. They were put in their places hot, and a quantity of melted tallow being first poured into the hole, when the hot irons were put down the tallow ran over on all sides, and thus certainly filled up all cavities. A quantity of coarse pewter, made red-hot, was now poured into the cavity round the irons, and, being a heavier fluid, displaced the tallow, and filled the space round them completely, the tallow effectually preventing the entrance of the sea water into the most minute cavities. This method is worthy of record, as it may be applied to many other useful purposes. Mr. Rudyerd, as before-mentioned, began his operations in July 1706; in July 1708, he had so far completed it as to exhibit a temporary light; and the whole was completed in the following year. This building had some repairs of its timbers in 1723, and again in 1744, when a violent storm had carried away a great number of the upright timbers; but it shewed itself, in the course of 49 years, to be a very excellent construction of its kind, and only liable to destruction from the perishable nature of its materials, or the catastrophe which awaited it on the night of the 1st of Dec. 1755, when one of the attendants, entering the lantern to snuff the candles, found it in flames, and, notwithstanding every exertion, the fire communicated to the uprights, and burned downwards. The unfortunate men descended

scended from room to room as the fire increased, and were at last obliged to take refuge, from the fall of burning timbers, in a cavity of the rock, from which they were relieved by a boat the next morning. The wind, unfortunately, blew from the east, and though it caused such a swell as to prevent landing, did not break on the house so as to extinguish the fire; and thus, in a few days, the whole was destroyed, except the iron cramps in the rock.

It is remarkable, that whilst one of the light keepers, at the commencement of the fire, was looking up at the fire in the cupola of the lantern, a body of melted lead showered down upon him, and he declared a quantity had passed down his throat into his stomach. He lived only 12 days after being taken on shore; and on opening the body, a mass of lead was taken from the stomach, weighing more than seven ounces. The curious fact, of his having 12 days survived so alarming an accident, was communicated by his attendant surgeon, Dr. Spry, to the Royal Society, but the circumstance appeared so improbable, that it did not, at first, meet that credit, which future experiments on animals proved he was entitled to.

On the news of the fire reaching London, the proprietors (for by the sale of Capt. Lovell's original lease, the property of the light-house was now in many hands,) immediately took measures to restore it, and appointed one of their members, Mr. Rob. Weston, to the sole management of their affairs, and he being recommended to Mr. John Smeaton, F.R.S., by the president of the Royal Society, employed this gentleman to devise the means, and superintend the erection, of a new building. Mr. S., whose originality of genius, and soundness of judgment, have since been so generally known, was at that time just entering into his profession as a civil engineer, but immediately devoted himself to the consideration of the light-house, and soon determined upon erecting a stone building; and reasoned, that by making the building very heavy, and uniting all the stones firmly together, he should obtain such a weight and strength, as would firmly resist the united action of the wind and water. He determined upon dovetailing the stones together, as being a more secure method than cramping with iron, and not liable to interruption from the work getting wetted, as would almost unavoidably happen in such an exposed situation. On the whole, the building he erected, and which is now standing, may be considered as the most perfect light-house in existence, and gives examples of the best kinds of masonry. We have therefore given drawings of it in the *Plate of Light-houses*, which are taken from a superb work in folio, published by Mr. Smeaton in 1791, entitled "Narrative of the Building, and Description of the Construction of the Eddystone Light-house with Stone." It is from the same source the whole of this article has been compiled.

Fig. 1. is a south elevation of the whole house, and *fig. 2.* a section of the same. A represents the landing place; B a natural cave in the east side of the rock; D an iron rod, serving as a rail to hold by in passing up steps cut in the rock, to the foot of the ladder occasionally put out from the entry door at E. At F is a cascade of water, pouring over a low part of the rock, but this is only momentary, for the swell will in an instant cause it to fet the other way. In *fig. 2.* a B shews the upright face of the rock, and the line *ab* the general direction of its grain or slope. In this figure it is seen that, as high as the first 14 courses of stone work, the building is entirely solid. Here the entry F commences, but excepting this cavity, and the staircase X, the solid still continues to the floor of the lowest chamber G, which is the store room, and H the door at which the stores are drawn up and received. I is the upper store room; K the kitchen con-

taining the fire-place L, from which the smoke ascends by a copper funnel *m*, through the bed room M and lantern N, to the ball on the top of the cupola O. The ascent from room to room is by the perforations through the middle of each floor, a moveable step ladder being used for the attendants; but here may be drawn up from the lower room into any other. P is the railing forming the balcony; its floor is covered with very thick sheet lead, turned down over the cornice Q, which surmounts the column of the building. R is the stone base of the lantern, and N the glazed part: the cupola O is supported by eight cast-iron standards, between which the copper window frames are fixed: the standards have claws at bottom, which are screwed to flat iron bars resting upon the stone work. By this means the whole lantern is framed together; and to strengthen it, the window frames are cast with diagonal bars, as shown in *fig. 2.* The whole lantern is held down by eight bolts at its angle, passing down through the balcony floor; one of these is seen at *d*: S is the door to the balcony. The lantern is lighted by 24 candles arranged in two iron circles, one six feet four inches diameter, containing 16 lights; and the other, three feet four inches diameter, holding eight candles. These circles are suspended by cords going over pulleys, so that they mutually rise and fall parallel, and counterbalance each other. By this arrangement either circle can be drawn down to snuff the candles, which is done every half hour, without losing the whole light. Having thus described the general outline of the building, the minutia of its construction comes next to be described, and the manner of uniting the stones composing it. The section, *fig. 2.* shews the several steps which were cut in the rock to engraft the stone work upon. *Figs. 1, 2, 3,* &c. denote the different courses of stone, each of which makes a level surface with the step it is fitted into. The seventh is the first complete course. *Fig. 3.* is a plan of the rock, shewing the courses 1, 2, and 3, laid in their places, and exhibiting the dovetails which are cut in each step to hold the several stones in their places; and these stones are so formed as to enlock the others with them in a manner which will prevent any stone quitting its position. The dark shaded stones are *moor* stones, while the lighter sorts are Portland stone. *Fig. 4.* is a plan of the seventh or first complete course, shewing a central stone with four dovetails uniting it to four others, and these tying in the remainder. All the solid courses are laid in this manner to the fourteenth, which, as before mentioned, completes the entire solid. Every course is laid in such a manner upon the one beneath it, that all the joints break each other, as masons term it, that is, immediately above and below the joints of any course the middle of a solid stone is disposed. The several courses are retained upon each other, to prevent them sliding sideways, by means of *joggles*, which are plugs or cubes of hard black marble, shewn by the dark squares in *fig. 2.* and in the plan, *fig. 4.* to be received one-half through every two adjacent courses. All the courses of the entire solids have a central joggle *j*, and eight others, *g*, arranged in a circle round it, as shewn in *fig. 4.* Above the entire solid, the centre stone is omitted to leave the well-hole for the staircase, X, or rather, it is composed of four stones, united by hook or dovetail joints, to form, when put together, one piece, large enough to have the well-hole through its centre, and the exterior stones are united to it as a central piece in the same manner, as *fig. 4.* In these courses the continuity of the stones being somewhat broken, double the number of joggles, *h*, and these half the size, are introduced between the courses. It is to be observed, that none of the joggles, except the centre ones,

come immediately over the others, as the figure would infer, but they break joint with each other to give every part of the solid an equal strength. Above the solid, a new system of building was necessarily adopted: the lower courses were composed of Portland stones to fill up the centre, and moor stones, as being more durable, to make the outside. The whole of the upper works are of moor stone; and dovetailing being no longer practicable, the stones are united by iron cramps and joggles, as shewn in *fig. 7*, which is a plan of the upper or bed-room M. Each stone is here seen to have an iron cramp to join it to its neighbour, and has a small marble joggle to unite it with that above it. The vertical joints are rendered impervious to water, by cutting a notch between every two adjacent stones, so that when they come together it forms a hole of a lozenge shape, and a piece of stone being put down into this hole with mortar, makes a perfect joint, at the same time increasing the bond of the stones. This kind of joint is partly seen in *fig. 8*, at *n*, but one-half is hid by the iron cramps *r, r*, extending over every joint. In this figure they are seen inclined, that they may take firmer hold of the stones *s, s*, forming the sides of the apertures T, for the window. The stones of the different floors are dovetailed together, as in *figs. 5* and *7*, and are rather arched on the lower side, as shewn in *fig. 2*. To retain the thrust of these arches, every course from which a floor springs, is bound by an endless chain inland in the stone work, as in *fig. 5*, and run in solid with lead. The chain is shewn enlarged in *fig. 6*. *Fig. 7*, is a plan of the bed-room M, shewing the disposition of the three cabin beds *k, l, m*, with a window between each. The dark spot *m* is the smoke funnel, and *n* is the place for a clock.—The reader is now tolerably well acquainted with the construction of Mr. Smeaton's light-house; but in such a peculiarly exposed situation, every trifling operation was attended with difficulty, and demanded thought and ingenuity to devise the means of accomplishing it. On this account we shall briefly follow Mr. Smeaton through his narrative, though it relates circumstances which, if recorded in the account of a common building, would appear impertinently minute. The season when Mr. Smeaton first took up the business of the light-house not being favourable for a visit to the rock, he did not attempt it till April 1756, before which time he had designed the general principles of the building. He found upon the rock the ruins of both the former erections, and several of the moor stones of the late building lying in the gut, which was a narrow channel of twelve feet deep between the house rock, and a reef of rocks to the wellward, in which channel the boats coming to the house could lie in fair weather. His first visit was employed in observations on the rock, and in experiments of the time requisite to drill and pick holes of a certain dimension, that he might estimate the time necessary to complete the work on the rock. In succeeding voyages he took dimensions of every part to enable him to make an accurate model, to which he could adapt a model of the intended building. The unfavourable days at sea were employed on shore in examining the stone in the country round, a convenient situation for a work-yard, &c. The dimensions of the rock were taken by the following means: He fixed up the circle of a theodolite, with its index, in the centre of the rock, and leveled it with the spirit-level; a light rod was fixed to the index, long enough, when turned round, to reach all parts of the rock; it was provided with a spirit-level to shew when it stood horizontal. It is obvious that this rod, when turned round, would describe a horizontal plane, and the depth of any point of the rock beneath this plane was ascertained by a rod set up vertically upon the point in question, and ap-

plying the horizontal ruler to it. The divisions on the vertical rod shewed the depth; and the division of the horizontal ruler shewed the distance from the centre, and the degrees of the theodolite circle pointed out the direction. By these means the position and altitude of thirty-two principal points were obtained, which were well marked upon the rock, and a line being stretched from one of these points to another, gave the means of determining the position of the iron flanchions, or any thing else which was remarkable. Having thus, in ten voyages, made all the necessary observations on the rock, and determined upon regulations for the management of the work, he returned to London, and, in his way, visited the various stone quarries in Devonshire, and the isles of Portland and Purbeck. He was employed, till the month of July, in making exact models of the building, when he returned to Plymouth, where he found a vessel, the Neptune Bufs, which had been fitted up for exhibiting a temporary light during the period of rebuilding the house. From some misunderstanding between the Board of Trinity and the proprietors, this vessel was not employed in this manner, but was devoted to Mr. Smeaton's use, who immediately began the works upon the rock; mooring the Bufs near the rock to serve as a retreat for the workmen, who were frequently driven off by the waves. In the month of September the three lower slips of the rock were completed, and the upper ones in a state of great forwardness; after which time, bad weather prevented much more being done that year, and in November the Bufs left her moorings to return to Plymouth, in which voyage she was driven to sea, and narrowly escaped shipwreck. Thus concluded the operations of the year 1756. The winter season was passed in preparing stone work on shore, in building boats, and, by Mr. Smeaton, in a long and valuable series of experiments on the different kinds of cements, which could be applied to the building.

In May 1757, the Bufs was carried out and moored, and on the 12th of June the lowest and first stone was laid in its place; from the great uncertainty of the weather every stone was so contrived, that it was of itself in a condition to resist the wash of the sea, even when it was immediately laid, and before it was hardened. For this purpose, each stone had one or two holes drilled through it before it left the work-yard, and this hole being continued a few inches into the rock or the stone beneath, a strong trenail, or oaken pin, was driven through it, to pin it fast in its place: as the dovetails did not of course fit perfectly close into each other, but left space for the mortar; notches were cut in the edges of each stone to receive strong oak wedges, which held them firm until the mortar came to its solidity. As a further precaution to defend the mortar, all the outward joints were coated over with plaster of Paris, as a temporary expedient. The work went on rapidly in this manner, and the second course was nearly set in a few days; but a gale sprang up, which obliged them to quit the work, leaving a few stones of the second course, which could not be set, lowered down into their places, and chained strongly to the rock, by lines inserted into the holes made in each of the stones, to lift them by; and one of the most exposed was secured, by laying upon it, when in its dove-tail, a weight of lead of five cwt. in form of a hemisphere. A storm came on, and it was afterwards found, that this weight had been lifted by the waves, so that the stone beneath it had escaped and was lost, as were four others, from which circumstance the force of the sea on the rock may be imagined. New stones were immediately prepared, and the work renewed. In the progress of the work, it constantly happened, after all precautions, that the cement was washed away in particular places,

LIGHT-HOUSE.

places, and it was always repaired the first opportunity with Pozzolana or Dutch terras; which repairs, if they withstood one rough tide, were never found to fail afterwards; but some places were found so difficult, that it became necessary to mix oakum, chopped very small, with the mortar, and this method always succeeded. On the 11th of August the six basement courses were completed, and the first entire course, N^o 7, was begun. All the stones for this course were fitted and put together in the work-yard, as shewn in *fig. 4*. They are numbered, so that after being taken to pieces, they could be restored to the same relative position on the building; but to do this accurately, while they were in the work-yard, radial lines were drawn from the centre to the circumference, so as to intersect each stone; and concentric circles were drawn through the middle of each tier of stones. Where any of these lines crossed the joints, a nick was sawn in the edge of the stone, that the mark might be felt as well as seen; and by the coincidence of these lines the stones were set with the greatest accuracy. On the stones arriving at the work, the central stone was first set; the hole to receive the centre joggle was cut through the centre of course six, and the joggle set up therein, as shewn in *fig. 2*, and the centre stone of course seven let down upon it, a mortar bed being made beneath. When the stone was thus fixed, the joints round the joggle were filed in by grouting, which is mortar made very thin and poured in from ladles. The four stones surrounding the centre were now set, and the work proceeded thus to the circumference, every stone being wedged and trenched as soon as set, and the joints grouted. To fix the eight smaller joggles, they were set, wedged, and grouted into their holes in the lower course; but the holes for their reception in the lower side of the upper course, being only cut half through, did not admit of wedging; they were therefore fixed by the mortar only, as much being put on the top of the joggle as would nearly fill the hole, but not quite, and the remainder was introduced through a hole previously drilled through the stone, and forced down by a wooden ramrod.

The mortar used in the building was compounded of equal portions of lime and pozzolana. The lime was burned from the blue Lyas limestone found near Watchet, a small seaport in Somersetshire. It was carried out in tight casks, which were opened at the rock, and a small quantity beat up in a strong bucket with a wooden pebble, and used immediately. The work proceeded in the same manner without any deviation or accident, except now and then losing a few stones by storms, until the end of September, when the ninth course, being completed, the work was given up for the year, and the Buys left her moorings.

During the winter, the buoy of the moorings for the Buys was lost, but was recovered on the 11th of May, 1758. Yet, before any work could be begun, the chains were broken, and the buoy of the anchors having got loose, the moorings were lost; much time being consumed in preparing new ones, it was the 2d of July before the work was renewed; but by the 8th of August, the 14th course, completing the entire solid, was laid, and by the 20th the entry door was covered in, and by the 24th of September, the whole of the solid, up to the store-room floor, was finished. Above this the method of working was totally altered, but not being now so liable to the action of the sea, it became less difficult, and requires less description. In addition to what has been said before, the iron cramps were all filled in their places with lead, and a whole course was done at once, by putting each cramp into a kettle of red-hot lead, till it was equally hot. A small quantity of oil was poured into the holes in the stone, and the hot cramp put in: this oil caused

the lead, when poured in, to occupy every cavity in the stone.

On the 30th of September, the work had arrived at the store-room floor, and here the iron chain, shewn in *fig. 5*, was let into the stone, and filled in with lead in the following manner:—the chain was oiled before putting it in, and the groove divided into four parts by dams of clay. Two kettles were used, which together would hold lead enough to fill the whole groove, which was 11 cwt. In these the lead was made red-hot, and two persons with ladles filled the lead into the same quarter of the groove. As soon as it was at all set, they removed one of the clay dams, and filled the next quarter, pouring the lead on the end of the first quarter, till it re-melted and united with the second. The dam at the opposite end of the first quarter was now removed, and the third filled, and then the 4th. By this means the lead was all round united in one mass.

The centering for the floor was next set up, and the floor partly put together, the outward stones being set first, and then the centre ones. When the first room had been thus finished, Mr. Smeaton proposed exhibiting a temporary light during the winter, and, by fixing three floors in the well for the staircase, to form store rooms, and lodging for two men: but this idea was given up, as it did not meet the approbation of the Trinity corporation, and the work was, on the 7th of October, left for the year, the floor being partly finished. The winter was spent in preparing the iron, glass, and copper work for the lantern; and the spring in unsuccessful endeavours to recover the moorings which were again lost, and on the 5th of July the work was begun again. They found one of the stones for the floor, which was lodged in the store room H the year before, had been washed down the well, and thence through the entry into the sea, though it weighed four or five cwt. The stones for the building had hitherto been raised out of the boats, by what are termed *shears*, formed of two poles, united at top, and their feet pitched on the rock close to the building, at a proper distance asunder. A block of pulleys was suspended from the top of the two beams, to take up the stone. The shears were supported by a tackle called a guys, which was attached to the top of the shears, and hooked to the far side of the building, so that the stone, being raised up from the boat by a windlass fixed on the rock at X, *fig. 1*, the guy was drawn in to swing the stone over the building. When the work got above the entry E, the stones were landed into it, and drawn up the well X by a tackle suspended from a small triangle set over the well; but when the floor was covered in, the hole in the centre being too small to let the stones come up, a smaller pair of shears were made to lie upon the building and rise as it advanced. These were worked by a windlass set up in the store room H, and as they hung over the sides of the building, they drew up the stones clear of the wall. The work proceeded in this manner till the 17th of August, when the last piece of the cornice Q was fixed, which completed the whole column, and the workmen were enabled to lodge in the building. The balcony rails P, and the stone basement R of the lantern, were soon completed; and by the 26th, the stairs and all the masonry were finished. The iron frame of the lantern was next screwed together in its place, all the joints being first smeared with thick white lead and oil to prevent them from rusting; it was then raised up on wedges a small height, and lead poured in the joint between it and the stone to make a solid bed for it upon the stone. On the 17th of September, the copper cupola O was set up, by a particular kind of shears made for the purpose, the guys, in different directions, being fastened to booms projected out from the

the several windows of the upper room. The next day the ball, which was double gilt, was screwed on; and by October the 16th, an electrical conductor was fixed, which finished the edifice. A light was then exhibited, which has been continued ever since without any particular occurrence, or any accident produced by the many violent storms which have happened since. Mr Smeaton has, in the title page of his narrative, given a representation of the house in a storm, as seen through a telescope from Plymouth, when the waves dash up against the building, till they meet the cornice Q, by which the water is thrown off in all directions in a white column, which envelopes the house like a sheet, and rises to at least double its height, though the top of the ball is 100 feet above low water. See BEACONS.

LIGHT Infantry. See INFANTRY. When the light infantry companies are in line with their battalions, they are to form and act in every respect as a company of the battalion; but when otherwise disposed of they may loosen their files to six inches.

The open order of light infantry is usually two feet between each file.

The files may be extended from right, left, or centre; in executing it, each front rank man must carefully take his distance from the man next to him on that side from which the extension is made: the rear rank men conform to the movement of their file leaders.

When light infantry men fire in extended order, it is to be a standing rule, that the two men of the same file are never unloaded together; for which purpose, as soon as the front rank man has fired, he is to slip round the left of the rear rank man, who will take a short pace forward, and put himself in the other's place, whom he is to protect while loading.

The extended order of light infantry varies according to circumstances and situations. They may sometimes loosen their files to three times the distance of open order. But the general rule is to allow convenient intervals for the rear rank men to slip by, and return after they have fired.

All movements of light infantry, except when firing, advancing, or retreating, are to be in quick time.

The officer commanding the company will be on the right, covered by a serjeant; the next on the left, also covered by a serjeant. The youngest officer in the rear. In extended order the post of the officers and serjeants is always in the rear at equal distances.

In marching by files the officer commanding leads: by divisions each officer leads one. The supernumerary officer, if there be one, is in both cases with the officer commanding, ready to obey any directions he may receive from him.

The arms of light infantry in general will be carried sloped and with the bayonet fixed. Flanking or advanced parties, however, or parties in particular situations, may carry them trailed, and without bayonets, for the purpose of taking a more cool and deliberate aim.

When the light infantry is ordered to cover the line to the front, the divisions will move from their inner flanks round the flanks of the battalions, and when at the distance of fifty paces, the leading flanks will wheel towards each other, so as to meet opposite the centre of the battalion, opening their files gradually from the rear, so as to cover the whole extent of the battalion.

The files are not to wait for any word of command, but to halt and front themselves. In this position, and in all positions of extended order, the post of the officer commanding is in the rear of the centre, and the movements

are to be regulated by the company belonging to the battalion, which governs those of the line. For a fuller explanation of light company manœuvres, see page 273 to page 281 of Infantry Regulations.

Light infantry men, like hussars, are frequently detached to act as scouts on the flanks, in the front, or with the rear guard of the body of troops to which they belong. They then acquire the appellation of skirmishers, and being previously told off for that specific duty, they advance and form in the front in rank entire; which is effected by each man from the rear rank placing himself on the left of his file leader. The rank entire may be resorted to for various purposes during the movements of one or more battalions, since it may serve not only to cover them from the enemy's observation, but in some cases, especially in foggy weather, will itself appear a larger body than it really is. Too much attention cannot be given to the organization of light troops on foot. They are very properly called the eyes of an army, and ought always to be considered as indispensably necessary.

LIGHT-ROOM, is a small apartment inclosed with glass windows, near the magazine of a ship of war. It is used to contain the lights by which the gunner and his assistants are enabled to fill the cartridges with powder, to be ready for action.

LIGHT TROOPS, in *Military Language*, generally denote all horse and foot which are accounted for detached service.

LIGHT WATER-LINE, in *Naval Architecture*, the line of floatation of the ship, before she takes in her cargo.

LIGHTEN, in the *Manège*. To lighten a horse, or make him light in the fore-hand, is to make him freer and lighter in the fore-hand than behind. If you would have your horse light, you ought to keep him always disposed to a gallop, when you put him to a trot; and after galloping some time, you should put him back to the trot again.

LIGHTER, a large open vessel, generally managed with oars, common on the river Thames, and on other rivers and canals; where it is used for the carriage of timber, coals, ballast, and any goods to or from a ship, when she is to be laden or delivered. There are also some lighters furnished with a deck throughout, in order to contain those merchandizes which would be damaged in rainy weather: these are usually called *close-lighters*. See BOAT.

LIGHTER-MEN. See COMPANY.

LIGHTFOOT, JOHN, in *Biography*, the son of a clergyman, was born at Stoke upon Trent, in Staffordshire, in the year 1602. He received his grammar learning at Moreton-green, near Congleton, Cheshire, after which he was entered a student of Christ's college, in the university of Cambridge. Here he applied himself with much diligence, and made so great a proficiency in classical literature, and the studies connected with it, that he was reckoned the best orator among the under graduates of the university. At the age of nineteen he quitted the university, and engaged himself as assistant to his old school-maister, who had, at that time, removed from Cheshire to Repton in Derbyshire. Having continued in this situation about two years, he took orders, and settled as curate at Norton-under-Hales, in Shropshire: about the same time he became chaplain to Sir Rowland Cotton, and resided in his family. This gentleman, being a perfect master of the Hebrew tongue, engaged Mr. Lightfoot in the study of that and the other Oriental languages. He followed his patron to London, and would have proceeded with him to the continent, but the living of Stone, in Staffordshire, being offered him, he preferred settling there, as it likewise gave him an opportunity of entering upon the marriage

state, which he immediately embraced. Here he found the means of study exceedingly scanty, and in the course of a few months resigned the living of Stone, and removed to Hornsey, near London, a situation which he chose, on account of its vicinity to the metropolis, where the sources of learning were very abundant. He was now a frequent attendant at the library of Sion-college, which afforded him the most ample means of supplying all his literary wants. In 1629, Mr. Lightfoot published his first piece, entitled "Erubhim; or Miscellanies Christian and Judaical, and others, penned for the recreation of vacant hours." In 1630, he was presented by sir Rowland Cotton to the rectory of Ashly, in Staffordshire, and immediately removed to his parish, in which he lived twelve years, applying himself with indefatigable diligence in searching the scriptures, and in the performance of various duties attached to his office, as a conscientious clergyman. He was next appointed by the Long Parliament a member of the assembly of divines at Westminster; and as he could no longer reside among his parishioners he resigned the rectory, but obtained the presentation for a younger brother. He arrived in London in 1642, and was almost immediately chosen minister of St. Bartholomew's, behind the Royal Exchange. In the assembly of divines, which met in June 1643, Mr. Lightfoot became distinguished for his eloquence in debate, and activity in business. He was friendly to the Presbyterian form of church government, which he declared in a sermon before the house of commons, he verily believed was "according to the pattern in the mount." In 1643 he was appointed master of Catherine-hall, in Cambridge, and in the same year he was presented to the living of Much-munden, in Hertfordshire. In 1644 he published the first part of his "Harmony of the New Testament," with a plan of his whole design, and continued afterwards to send out, at different periods, the other branches of the same work. In 1652, Mr. Lightfoot took the degree of doctor of divinity, and went through all the regular exercises, on that occasion, with great applause. In 1653 he was chosen vice-chancellor of the university of Cambridge, the duties of which important office he performed with exemplary diligence and fidelity. Upon the restoration of king Charles II. Dr. Lightfoot offered to resign the mastership of Catherine-hall in favour of Dr. Spurstow, but upon his declining to accept it, our author obtained a confirmation from the crown of that place, and of his living. For these marks of royal favour he was chiefly indebted to the kindness of archbishop Sheldon, who, out of pure respect for his learning and talents, undertook to serve him. Soon after this he was collated, through the interest of lord-keeper Bridgman, to a prebend in the cathedral church of Ely. In 1661 he was appointed one of the assistants at the conference at the Savoy on the subject of the liturgy, but he attended only twice, on account of the violence displayed in the debates. He now gladly withdrew as much as possible from the world, in order that he might spend his time in studies to which he was attached, and which he prosecuted with vigour to the last. His publications would have been more numerous, but the expense of them was more than he could bear, and he never was sufficiently patronized by the public to interest the booksellers in his behalf. A short time before his death he was, however, requested by them to collect and methodise his works, in order that they might be printed in an uniform manner. He died in December 1675, before he could accomplish the task required of him, in the 74th year of his age. Dr. Lightfoot was indefatigable in his pursuits, and extremely temperate in his mode of living. He lived in the greatest harmony among his parishioners,

being easy of access, affable, communicative, hospitable, and charitable. As a writer he was one of the most ingenious, as well as learned, of our English commentators, and has furnished his successors with very valuable materials in the same line of studies: he had few equals, and no superior in rabbinical literature; and in this branch of learning his celebrity was so great, that many foreigners came to him for assistance in it. His works were collected and published in 1684, in two volumes folio. A new edition of them was published in Holland in 1686, containing all his writings that had been originally given to the world, in the Latin language, and a Latin translation of those which he had written in English; and a third edition was published at Utrecht in 1699, by John Leusden: this impression contained some posthumous pieces, which were comprised in a third volume. These were, in the following year, published in an 8vo. volume by Mr. Strype, under the title of "Some genuine Remains of the late learned and pious Dr. John Lightfoot." The doctor was not only indefatigable in his own pursuits, but an encourager of other learned men in theirs. He gave great assistance in completing the English Polyglott bible, by drawing up a chorographical table prefixed to it, and by superintending the sheets of the Samaritan version, as they were printed: he afforded much pecuniary assistance to Dr. Castell in the publishing of his Heptaglott Lexicon, which would otherwise have occasioned his entire ruin for want of support from the learned world: and Dr. Lightfoot was the person who excited Mr. Pool to undertake his valuable work entitled "Synopsis Criticorum." Biog. Brit. Gen. Biog.

LIGHTFOOT, JOHN, a distinguished British botanist, chiefly known as the author of the *Flora Scotica*, was born in 1735. He was educated at Oxford, where he took the degree of Master of Arts, and having entered into holy orders, became chaplain to the late duchess dowager of Portland, "that great and intelligent admirer and patroness of natural history in general," as he justly denominates her in the dedication of his book. He was recommended to this illustrious lady, whose accomplishments gave a lustre to her high rank, by his taste for botany and conchology, as well as his courtly and assiduous manners, which, accompanied by an habitual pleasantry and cheerfulness, rendered his company generally acceptable. By her grace's influence, we believe, he obtained the rectory of Gotham, in Nottinghamshire, and subsequently the living of Cowley, in Middlesex.

In 1772, the late Mr. Pennant, so well known as a zoologist, invited Mr. Lightfoot to be the companion of his second tour to Scotland and the *H. brides*, advising him to undertake the "compilation," as he himself modestly calls it, of a *Flora Scotica*, which Mr. Pennant offered to usher into the world at his own expense. These generous and flattering offers Mr. Lightfoot gladly accepted, and made the most of the opportunity afforded him for "gratifying a favourite affection he had long conceived for the science of botany." He enjoyed "the enchanting prospect," to use his own words, "of examining a country whose vegetable productions had been attended to by very few." Our author was justly aware that a single summer could by no means be sufficient for the full accomplishment of such an undertaking, nor would he perhaps have ventured upon it, but for the assistance of "able and ingenious botanists, who had resided in that country their whole lives," who permitted him "to examine their collections, and freely communicated the observations of many years." These were the late Dr. Hope, professor of botany at Edinburgh; the Rev. Mr. (now Dr.) John Stuart of Luss; and the Rev.

Dr. Burgess, the venerable pastor of Kirkmichael in Dumfriesshire: three men whose urbanity conferred upon their beloved science her most attractive charm, as the writer of this can well testify. Mr. Stuart was the companion of our travellers in their excursion, and supplied each, in his own line, with much learned information, respecting the Erse nomenclature, as well as the real or supposed uses and history of the native animals and plants. Thus Mr. Pennant was enabled to prefix a compendious *Fauna* to the *Flora* of his friend; and thus Mr. Lightfoot found his path made straight and plain before him, and literally strewed with flowers. He profited likewise from the communications of Dr. Parsons, at that time professor of anatomy at Oxford, and of Mr. Yalden, an ingenious young man, whose premature death happened soon after. These gentlemen had cultivated botany in the course of their medical studies at Edinburgh, the latter especially, with eminent success. When Mr. Lightfoot's materials were got together, the library, herbarium, and personal superintendence, of his friend Sir Joseph Banks, in conjunction with the help of Dr. Solander, were of the most eminent and indispensable use; and the comparison of his cryptogamic specimens with those of Dillenius at Oxford, under the eye of the professor, or rather of his son Dr. John Sibthorp, gave the finishing stroke to his labours. Thus the *Flora Scotica* became ready for publication in 1777, when it appeared in two thick volumes 8vo. with 35, rather indifferently engraved plates, five of which are zoological. The work is disposed according to the system of Linnæus, with short essential generic and specific characters copied from that author, and references to a few of the best figures of each species. English, Scottish, and Erse names are subjoined, with the general or particular places of growth, duration, &c.; and the account of every plant finishes with a longer or shorter description in English, various botanical remarks, and compiled notes of its economical or medical uses.—The plan and the execution of this work appear calculated to render it one of the most popular Floras. It has found its way to the continent, where it is generally quoted, especially for the Cryptogamous class, which the author says “cost more time and attention than all the other 23 classes together.” Yet we have heard that this publication did not, for a long time at least, pay its expenses. This certainly did not arise from any want of merit; for its only great and radical fault was not known, or at least scarcely considered such, till lately. Of this notice is taken under the botanical article FRONV. The fault we mean is this: compiling descriptions from foreign authors, without mentioning whence they are taken; so that a student can never be certain of their just application, but, on the contrary, often finds them erroneous or unsuitable, without knowing why. Even in the last class, on which Mr. Lightfoot bestowed so much pains, the synonyms of Linnæus and Dillenius often disagree, though in many cases such contrarieties are properly indicated, so as to throw original light on the subject.

Mr. Lightfoot was for some years a fellow of the Royal Society, and was one of the original fellows of the Linnæan Society, the formation of which he contemplated with great pleasure, though his death happened before he could attend any of its public meetings. Having married the daughter of an opulent miller at Uxbridge, he resided in that town, and died there suddenly in the spring of 1788, aged 53, leaving a widow and several daughters. He was buried in Cowley church, where his grave remained, for some time at least, without any memorial. He is supposed never to have recovered from a distemper, respecting a living, which

his patron, the late duke of Portland, solicited from Lord Chancellor Thurlow, but which the latter did not think fit to bestow.

The subject of our memoir had, in the course of his botanical studies, collected an excellent British herbarium, consisting of abundant specimens, generally gathered wild, and in many cases important for the illustration of his work. He had also amassed, from Sir Joseph Banks and other friends, a number of exotic plants. The whole was bought, after his death, for 100 guineas, by his majesty, as a present to the queen, and deposited at Frogmore, the price being fixed by an intelligent friend of the family. The specimens having been for some time neglected, were, after a while, discovered to be much infested with insects; and as their royal possessor, having a genuine and ardent taste for the study of botany, was anxious for their preservation, the writer of the present article was requested to give his advice and assistance on this subject. This led to his frequent invitation as a visitor at Frogmore, and to a regular course of conversations, rather than lectures, on botany and zoology, which her majesty, and the princesses Augusta and Elizabeth honoured with their diligent attention; the queen regularly taking notes of every lecture, which she read over aloud at its conclusion, to prevent mistake. The plan of this exemplary mother, on which she has often been heard to decant, was, in the education of her royal offspring, to open as many resources to them as possible, in a variety of studies and pursuits; out of which they might subsequently make their own choice, and thus be independent of circumstances for occupation and amusement. Nor has the herbarium of Lightfoot been confined to useless repose. It was allowed to be consulted frequently, on the subject of Scottish Willows, and other doubtful matters, while the *Flora Britannica* was preparing; and the present bishop of Carlisle was permitted to make all requisite use of it, for the completion of his valuable paper on British *Carices*, printed in the second volume of the Linnæan Society's Transactions. In the knowledge of these two genera of plants, Mr. Lightfoot excelled most botanists of his day; but the specimens of Linnæus, being compared with his, have brought errors to light, which were never suspected before. S.

LIGHTFOOTIA, in *Botany*, so named by L'Heritier, in honour of the author of the *Flora Scotica*. (See LIGHTFOOT) L'Herit. Sert. Angl. 4. Ait. Hort. Kew. v. 1. 217. ed. 2. v. 1. 343. Wild. Sp. Pl. v. 1. 887. Juss. 450—Class and order, *Pentandria Monogynia*. Nat. Ord. *Campanulaceæ*, Linn. *Campanulacæ*, Juss.

Gen. Ch. Cal. Perianth of five equal, acute leaves, broad at the base, encompassing the middle of the germen. Cor. of one petal, in five deep, equal, regular, oblong, spreading segments, rather longer than the calyx; the very short tube closed by five valves, bearing the stamens. Stam. Filaments five, linear, flat, equal, much shorter than the corolla; anthers small, roundish, incumbent. Pist. Germen half inferior, ovate, style thread-shaped, about the length of the corolla; stigma dilated into three or five, somewhat spreading, segments. Peric. Capsule ovate, with three or five cells, opening at the top by as many valves. Seeds numerous, small, roundish.

Efl. Ch. Corolla in five deep segments, closed at the bottom by valves bearing the stamens. Calyx of five leaves. Stigma of three or five lobes. Capsule half superior, of three or five cells, and as many valves.

1. *L. oxycoccids*. Cranberry-leaved Lightfootia. L'Herit. Sert. Angl. 4. t. 4. Sm. Exot. Bot. v. 2. 19. t. 69.—(*Loebelia tenella*; Linn. Mant. 120. Thunb. Prodr. 40. *L. parviflora*;

parviflora; Berg. Cap. 345.)—Leaves plain, ovato-lanceolate, alternate, reflexed. Stigma three-cleft. Corolla widely spreading.—Native of the Cape of Good Hope, as are the two following species also. This was sent to Kew in 1787, by Mr. F. Maffon. It is kept in the greenhouse, and flowers from July to September. The *stem* is perennial, shrubby, of humble growth, bushy and spreading, not prostrate, very much branched, often finely downy. *Leaves* numerous, small, alternate, sessile, reflexed, ovate or somewhat lanceolate, acute, smooth, thick-edged, entire, except a small glandular tooth or two at each side. *Flowers* small, on little, terminal, naked, simple stalks. *Corolla* white, with a tinge of purple along the middle of each segment. *Stigma* purple. *Capful* of three pointed valves forming a cone.

2. *L. tenella*. Curve-leaved Lightfootia. (*Campanula tenella*; Linn. Suppl. 141.)—Leaves ovato-lanceolate, channelled, clustered, recurved. Stigma three-cleft. Corolla widely spreading, with narrow linear segments. Stigma three-cleft. Gathered by Thunberg at the Cape. It seems a stranger to our gardens. L'Heritier confounded it with the preceding, from which it differs in its very numerous, clustered, recurved, and deeply channelled *leaves*, and the longer and narrower segments of the *corolla*. We cannot but think it more than a variety, though there is scarcely any difference besides what we have mentioned.

3. *L. fululata*. Awl-leaved Lightfootia. L'Herit. Sert. Angl. 4. t. 5.—Leaves awl-shaped. Calyx almost altogether inferior. Corolla moderately spreading, with linear segments. Stigma five-cleft.—Sent to Kew by Mr. Maffon in 1787, from the Cape.—This is distinguished by its copious, awl-shaped, very narrow *leaves*, sometimes near an inch long. The shrubby *stem*, with downy *branches*, accords nearly with the two former. The *flowers* stand on shorter stalks, and have longer sharper calyx leaves, tumid at the base, and almost perfectly inferior. Segments of the *corolla* moderately spreading, recurved, narrow, white or bluish. *Stigma* five-cleft. *Capful* we presume of five valves.

Nothing can agree more exactly with this as to habit than *Campanula paniculata*, Linn. Suppl. 130, and *Trachelium diffusum*, 143; but their corolla has a long tube. The capsule of this supposed *Campanula* has five valves opening at the top, exactly as in *Lightfootia*, not by pores laterally, and the calyx is half superior, so that it certainly belongs to the same genus, the length of the tube of the corolla being of much less importance.

LIGHTFOOTIA is also the name of an arboresecent genus of the *Polyandria Monogynia*, in Swartz's Fl. Ind. Occ. v. 2. 947, referred to *Prockia* in Willd. Sp. Pl. v. 1. 1214. This is *Lightfootia* of Mart. Mill. Dict. v. 3.

LIGHTNESS. See LEVITY.

LIGHTNING, in *Physiology*, is a large bright flame, darting swiftly through the air, and extending every way to a considerable distance, of momentary duration, and commonly attended with thunder. Some have accounted for this phenomenon by supposing, that, from the particles of sulphur, nitre, and other combustible matter, which are exhaled from the earth, and carried into the higher regions of the atmosphere, is formed an inflammable substance, which, when a sufficient quantity of fiery particles is separated from the vapour buoyed up into the air, with these particles adhering to them by the collision of two clouds or otherwise, takes fire, and shoots out into a train of light, larger or less, according to the strength and quantity of the materials. Others have explained lightning by the fermentation of sulphureous substances with nitrous acids: see THUNDER. But in the present advanced state of the science of electri-

city, this is universally allowed to be an electrical phenomenon. Philosophers had not proceeded far in their experiments and inquiries on this subject, before they were struck with the obvious analogy between lightning and electricity, and they produced many arguments, *a priori*, to ascertain their similarity. But the method of verifying this hypothesis was first proposed by Dr. Franklin, who, towards the close of the year 1749, conceived the practicability of drawing lightning from the clouds: having long, by previous experiments, that the electric fluid is attracted by points, he apprehended, that lightning might likewise possess the same property; though the effects of the latter must, in an astonishing degree, surpass those of the former. The other circumstances of resemblance between lightning and electricity remarked by this ingenious philosopher, and abundantly confirmed by later discoveries, are the following: flashes of lightning, he observed, are generally seen crooked and waving in the air; and the electric spark drawn from an irregular body at some distance, and when it is drawn from an irregular body, or through a space in which the best conductors are disposed in an irregular manner, always exhibits the same appearance.

Lightning strikes the highest and most pointed objects in its way, preferable to others, as high hills, trees, towers, masts of ships, &c. and all pointed conductors receive and throw off the electric fluid more readily than those which are terminated by flat surfaces. Lightning is observed to take the readiest and best conductor; and this is the case with electricity in the discharge of the Leyden phial; whence the doctor infers, that in a thunder storm, it would be safer to have one's clothes wet than dry. Lightning burns, dissolves metals, (see FUSION,) rends some bodies, has been often known to strike people blind, destroys animal life, deprives magnets of their virtue, and reverses their poles; and these are well-known properties of electricity.

Lightning not only gives polarity to the magnetic needle, but to all bodies that have any thing of iron in them, as brick, &c.; and by observing which way the poles of these bodies lie, it may be known, with the utmost certainty, in what direction the stroke passed. Signor Beccaria supposes, that persons are sometimes killed by lightning, without being really touched by it; a vacuum of air only being suddenly made near them, and the air rushing out of their lungs to supply it; and with so much violence that they could never recover their breath. In proof of this opinion he alleges, that the lungs of such persons are found flaccid; whereas, when they are properly killed by the electrical shock, the lungs are found inflated; but this hypothesis is controverted by Dr. Priestley. In order to demonstrate the identity of the electric fluid with the matter of lightning, by actual experiment, Dr. Franklin contrived to bring lightning from the heavens, by means of an electric kite, which he raised, when a storm of thunder was perceived to be coming on; and with the electricity thus obtained, he charged phials, kindled spirits, and performed all other electrical experiments, which are usually exhibited by an excited globe or tube. This happened in June, 1752, a month after the electricians in France, of whom the most active were Messrs. Dalibard and Delor, followed by Mr. Mazeas and M. Monnier, pursuing the method which he had proposed, had verified the same theory; but without any knowledge of what they had done. In April and June, 1753, he discovered that the air was sometimes electrified positively, and sometimes negatively; and found that the clouds would change from positive to negative electricity several times in the course of one thunder-gust. He soon perceived that this important discovery was capable of being applied to practical

LIGHTNING.

use, and proposed a method, which he soon accomplished, of securing buildings from being damaged by lightning, by means of conductors. The English philosophers had not been less attentive to this subject than their neighbours on the continent; but for want of proper opportunities for trying the necessary experiments, and from some incidental circumstances that were unfavourable, they had failed of success. However, in July, 1752, Mr. Canton succeeded; and in the following month, Mr. Wilton and Dr. Devis observed nearly the same appearances which Mr. Canton had observed before. Mr. Canton also soon after observed, in a number of experiments, that some clouds were in a positive and some in a negative state of electricity; and that the electricity of his conductor would sometimes change from one state to the other, five or six times in less than half an hour. This variable state of thunder clouds was discovered by S. Beccaria, before he heard of its having been observed by Dr. Franklin, or any other person: and he has given a very exact and circumstantial account of the external appearances of these clouds. From his observations of the lightning abroad, and of his apparatus within doors, he inferred, that the quantity of electric matter, in an usual storm of thunder, is almost inconceivably great, considering how many pointed bodies, as trees, spires, &c. are perpetually drawing it off, and what a prodigious quantity is repeatedly discharged to or from the earth. This quantity is so great, that he thinks it impossible for any cloud or number of clouds to contain it all, so as either to discharge or receive it. Besides, he observes, that, during the progress and increase of the storm, though the lightning frequently struck to the earth, the same clouds were the next moment ready to make a still greater discharge, and his apparatus continued to be as much affected as ever; and, therefore, the clouds must have received at one place, in the same moment when a discharge was made from them in another; and, upon the whole, he infers, that the clouds serve as conductors to convey the electric fluid from those places of the earth that are overloaded with it, to those which are exhausted of it. This electric matter, the rise of which, from the earth into the higher regions of the atmosphere, is ascertained by the great quantities of sand, ashes, and other light substances, carried up with it, and scattered uniformly over a large tract of country, wherever it issues, attracts to it, and bears up with it the watery particles that are dispersed in the atmosphere. It ascends into the higher regions of the atmosphere, being solicited by the less resistance it finds there than in the common mass of the earth, which, at these times, is generally very dry, and consequently highly electric. The same cause which first raised a cloud, from vapours dispersed in the atmosphere, draws to it those that are already formed, and continues to form new ones, till the whole collected mass extends so far as to reach a part of the earth where there is a deficiency of the electric fluid. Thither, too, will those clouds, replete with electricity, be strongly attracted, and there will the electric matter discharge itself upon the earth: a channel of communication being in this manner formed, a fresh supply of electric matter will be raised from the overloaded part, and will continue to be conveyed by the medium of the clouds, till the equilibrium of the fluid between the two places of the earth be restored. When the clouds are attracted in their passage by those parts of the earth, where there is a deficiency of the fluid, those detached fragments are formed, and in a little these uniform descending protuberances, which are, in some cases, the cause of *Warr-sprouts* and *Hurricanes*; which see.

That the electric matter, which forms and animates the thunder-clouds, issues from places far below the surface of

the earth, and that it buries itself there, is probable from the deep holes that have, in many places, been made by lightning; and from the flashes that have been seen to arise from subterraneous cavities and from wells; as well as from the inundations accompanying thunder-storms, and occasioned by water bursting out of the bowels of the earth. The greatest difficulty attending this theory of the origin of electric matter within the body of the earth. With respect to the former, this ingenious philosopher has nothing to say: some operations in nature are certainly attended with a loss of the equilibrium in the electric fluid, but no person has yet assigned a more probable cause of the redundancy of the electric matter, which, in fact, often abounds in the clouds, than what we may suppose possible to take place in the bowels of the earth: and supposing the loss of the equilibrium possible, the same cause that produced the effect would prevent the restoring of it; so that not being able to force a way, at least one sufficiently ready, through the body of the earth, it would issue at the same convenient vent into the higher regions of the air, as the better passage. S. Beccaria observes, that a wind always blows from the place from which the thunder-cloud proceeds; and it is certain, that the sudden congregation of such a prodigious quantity of vapours must displace the air, and repel it on all sides. A great number of observations relating to the descent of lightning, confirm his theory of the manner of its ascent: for, in many cases, it throws before it the parts of conducting bodies, and distributes them along the resisting medium, through which it must force its passage. Upon this principle, the longest flashes of lightning seem to be made, by its forcing into its way part of the vapours in the air. One of the principal reasons why those flashes make so long a rumbling, is their being occasioned by the vast length of a vacuum, made by the passage of the electric matter. For although the air collapses the moment after it has passed, and the vibration, on which the sound depends, commences at the same moment; yet, if the flash was directed towards the person who hears the report, the vibrations excited at the nearer end of the track will reach his ear much sooner than those excited at the more remote end; and the sound will, without any repercussion or echo, continue till all the vibrations have successively reached him. Mr. Lullin, in order to account for the production of electricity in the clouds, made a long insulated pole to project from one side of the Alps, and observed, that when insular clouds of vapour, raised by the heat of the sun, rose near the foot of the mountain, and ascended along the side of it: if they touched the extremity of the pole only, it was electrified; but if the whole pole, and consequently part of the hill on which it stood, was likewise involved, it was not electrified. Whence he concludes, that the electricity of the clouds is produced by their passing through the air while the sun shines upon them. But to which of these two circumstances, namely, the motion through the air or the action of the sun's rays, this was owing, he could not determine, though he made several experiments for this purpose.

Upon the whole, it is easy to conceive, that when particular clouds of different parts of the earth possess opposite electricities, some being electrified positively, and others negatively, a discharge will take place within a certain distance; or the one will strike into the other, and in the discharge a flash of lightning will be observed. But how the clouds or earth acquire this state, is still a question not absolutely determined. Mr. Canton queries, whether the clouds become possessed of electricity by the gradual heating and cooling of the air; and whether air suddenly rarefied,

LIGHTNING.

may not give electric fire to, and air suddenly condensed receive electric fire from, clouds and vapours passing through it. Mr. Willeke supposes the air to contract its electricity, in the same manner as sulphur and other substances do, when they are heated and cooled in contact with various bodies. Thus the air, being heated or cooled in the neighbourhood of the earth, gives electricity to the earth, or takes it from it; and the electrified air, being conveyed upwards by various means, communicates its electricity to the clouds. Others have queried, whether, since thunder generally happens in a sultry state of the air, when it seems replenished with some sulphureous vapours, the electric matter then in the clouds may not be generated by the fermentation of sulphureous vapours with mineral or acid vapours in the air.

Dr. Franklin advises persons who are apprehensive of danger from lightning, to sit in the middle of a room, provided it be not under a metal lustre suspended by a chain, sitting on one chair, and laying their feet on another. It is still safer, he says, to bring two or three straw mats, or beds, into the middle of the room, and folding them double, to place the chairs upon them, for as they are not so good conductors as the wall, the lightning will not choose to pass through them: but the safest place of all is in a hammock hung with silk cords, at an equal distance from all the sides of a room. Dr. Priestley observes, that the place of most absolute safety must be the cellar, and especially the middle of it; for when a person is lower than the surface of the earth, the lightning must strike it before it can possibly reach him. In the fields, the place of safety is within a few yards of a tree, but not quite near it. Nevertheless, S. Beccaria cautions persons not to depend upon the neighbourhood of a higher, or, in all cases, a better conductor than their own body; since, according to his repeated observations, the lightning by no means descends in one undivided track; but bodies of various kinds conduct their share of it at the same time, in proportion to their quantity and conducting power. See on the subject of this article Franklin's Letters; Beccaria's *Lettre dell' Elettricità*; Priestley's *History, &c. of Electricity*, passim. Lord Mahon (now earl Stanhope) observes, that damage may be done by lightning, not only by the main stroke, and lateral explosion, but likewise by that which he calls the returning stroke, that is, by the sudden violent return of that part of the natural share of electricity (of any conducting body, or of any combination of conducting bodies) which had been gradually expelled from such body or bodies respectively, by the superinduced elastic electrical pressure of a thunder cloud's electrical atmosphere. See an account of his theory and experiments, relating to this subject, in his *Principles of Electricity*, &c. quarto, 1779.

The author of the *Philosophy of Agriculture* remarks, that the blaits occasioned by lightning are more frequent, he believes, than is usually supposed; as he is informed by those who purchase extensive woods, that very many trees, on being sawed through, are found cracked and much injured by lightning. He had last year (1796) a standard apple-tree and a tall apricot tree in full leaf, blasted at the same time by lightning, as was believed. They both lost all their leaves; the apple-tree, nevertheless, put out a new foliage and recovered, and bore fruit this year; but the apricot, which was nailed to a high wall, never threw any returning life. Mr. Tull, he remarks, ascribes one injury to lightning, the effects whereof may be observed by the blackish parts or patches visible in a field of wheat, especially

in those years which have more thunder storms than usual, and adds, that against this there is no remedy. The erection of frequent metallic points could, as the doctor thinks, alone secure a garden or field from this misfortune; which probably occurs more frequently on damp situations than on dry ones.

He conceives, that the manner in which lightning destroys the life of vegetables may be similar to that in which it destroys animal life; which is, he supposes, by its great stimulus, exhausting the sensorial power in the violent action it occasions, and thus producing total irritability to the common stimuli, which ought to excite the vital actions of the system. It may also affect vegetables in another way similar to that, which probably also happens when their young succulent roots are frozen; that is, by bursting their vessels, as it passes through them by its expansive power; as happens to the large branches of some trees, and to stone buildings, and other bad conductors of electricity, when they are struck with lightning. The expansive power of electricity is not only shown by trees and towers being rent by lightning, but by the sound which succeeds the passage of it through air; since a vacuum, or nearly a vacuum, in respect to air, must previously be made by the presence of the electric fluid: and the sides of this vacuum rushing together, when the stream has passed, occasion the consequent vibrations of the air, which constitute sound, whether in the audible spark of electricity, or the tremendous crash of thunder. Some other effects on vegetables have been ascribed by writers to lightning, but they have not yet been satisfactorily proved. See *ELECTRICITY*.

LIGHTNING, Artificial. The phosphorus, when newly made, gives a sort of artificial lightning visible in the dark, which would surprise those who are not used to such a phenomenon: the usual method of keeping this preparation is under water, and if the corrugations are desired to be seen to the greatest advantage, the glass in which it is kept should be deep and cylindric, and not more than three-fourths filled with water. The phosphorus put into this water will send up corrugations at times, which will pierce through the incumbent water, and expand themselves with great brightness in the empty upper part of the bottle.

If we compare this artificial corrugation to the real lightning, we shall find, that as in this the fire passes unaltered through the water, so in that the flashes of lightning, which come at intervals, pass uninterrupted through the most dense clouds, and are not obstructed by the heaviest storms of rain, but like the beams of the sun, or any other fire, pass uninterrupted through glass and water. The season of the weather, as well as the newness of the phosphorus, must concur to produce these flashes; for they are as uncommon in winter as lightning is, but in warm weather both are very frequent.

The flame of lightning is generally inoffensive, and does not, except upon particular circumstances, set fire to any thing that it falls upon: and in like manner, the flashings of the phosphorus through the water will not burn the flesh, nor even fire the most combustible things; though the phosphorus itself, like the lightning, under proper circumstances, may be a very consuming and terrible fire. The warmth of the air, or the immediate beams of the sun, will set fire to the condensed body of the phosphorus, and it then becomes this terrible fire; and in the same manner lightning, when condensed and contracted, and wrapped up in a vehicle of air, so that it does not so easily diffuse itself through the yielding ether, sets fire to trees, houses, or whatever it comes near.

The phosphorus, while burning, acts the part of a corrosive, and when it goes out resolves into a menstruum, which dissolves gold, iron, and other metals; and lighting, in the same manner, melts the same substances. From the whole, it appears that there is much more resemblance between this phosphorus and lighting than between gunpowder, or burning sulphur, and that fire; though these have often been supposed to be nearly allied to its nature. See PHOSPHORUS.

LIGNAC, JOSEPH ADRIAN LE LARGE DE, in *Biography*, a learned French abbe, descended from a noble family, and born at Pontiers about the commencement of the last century. He was brought up among the Jesuits, and in the course of time was chosen to fill different confidential posts in that order, and in the Congregation of the Oratory. During a visit which he had occasion to pay to Rome, he was introduced to the pope Benedict XIV. and cardinal Passionei, who honoured him with attention and friendship. He died at Paris in 1762, leaving behind him a considerable reputation as a philosopher, a naturalist, and theologian. He was author of "Elements of Metaphysics deduced from Experience;" "The Possibility of Man's Corporeal Presence in different Places at the same Time," in which he attempts to prove that the doctrine of transubstantiation contains nothing in it incongruous with the principles of sound philosophy. "An Examination of the *Traité de l'Esprit* of Helvetius." As a naturalist, we have "Memoirs Philistat of Aquatic Spiders;" "A Letter to an American concerning the Natural History of M. de Buffon;" and as a divine he published "The Testimony of internal Sense and Experience, opposed to the profane and ridiculous Creed of modern Fatalists," in three vols. At the time of his death he was employed in composing a treatise "On the Evidences of Religion."

LIGNE, in *Geography*, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Ancenis; 9 miles N.W. of Ancenis. The place contains 1642, and the canton 5770 inhabitants, on a territory of 137½ kilometres, in 4 communes.

LIGNEA CASSIA. See CASSIA.

LIGNEVILLE, the MARCANTINE DE, in *Biography*, an ingenious and learned dilettante at Florence in 1776, who had studied counterpoint so seriously as to be able to set the "Missa Salve Regina" in canon for three voices. The composition is correct, and neatly engraved, copies of which were given to his friends. In the title of this production, dated 1775, the marquis de Ligneville is styled prince of Conca, chamberlain to their Imperial majesties, a sector of the music of the court in Tuscany, and member of the Philharmonic society of Bologna. He was son of the famous marshal Ligneville, who was killed in the gardens of Colorno, a villa belonging to the duke of Parma, during the war of 1733, and was prince of Conca, in the kingdom of Naples, by right of his mother.

LIGNICEN: IS TERREA, in the *Materia Medica*, the name of a fine yellow bole, found in many parts of Germany, particularly about Emmerin, in the circle of Westphalia, and used in cordial and astringent compositions. It is a common fire clay, and for the yellow Silesian bole, where that is not to be had, and is generally esteemed very nearly, if not absolutely, equal to it in its virtues.

It is not so heavily, naturally of a smooth surface, and of a beautiful gold colour. It easily breaks between the fingers, and does not retain the skin in handling, melts freely in the mouth, and leaves no grittiness between the teeth, and is immediately dissoluble in water. It makes no effluence

with acids; and burns to a fine red colour, and almost to a stony hardness.

Charlton (Foss. p. 5.) says it is more frequently known by the name of *terra figillata Golbergenfis*.

There is another white bole known by this name. See GOLBERGENSIS terra.

LIGNIERES, in *Geography*, a town of France, in the department of the Cher, and chief place of a canton, in the district of St. Amand; 2½ miles S. of Bourges. N. lat. 46° 45'. E. long. 2° 15'. The place contains 1215, and the canton 655 inhabitants, on a territory of 26½ kilometres, in 14 communes.

LIGNITE. This name is given, by Brongniart, to the species of inflammable fossils, called *braun kelle* (brown coal) by Werner. The following account, from Brongniart's *Traité de Minéralogie*, will supply the omission of the article *Braun coal* in our work.

The combustible minerals belonging to this species are characterized by their small and the products of their combustion. The odour which they emit in burning is pungent, often fetid, and has no analogy with that of coal or bitumens. They burn with a pretty clear flame, without bubbling and caking, like coal, and becoming fluid in the manner of the solid bitumens; they leave powdery ashes similar to those of wood, but often more abundant, more ferruginous, and more earthy. The ashes contain a small portion of potash; at least Mr. Majon has found about 3 in 100 in those of the bituminous wood of Calchucovo. These combustibles yield an acid by distillation, which coal does not.

Lignites vary in colour from deep and shining black to a dull earthy-brown: the texture of most of the varieties indicates their origin and explains their name. The ligneous texture is often observable, though sometimes it has wholly disappeared. Its fracture is compact, often resinous and conchoidal, or shining and even.

The external characters of the varieties of this species vary too much to allow them to be further generalised.

1. *Jet Lignite*; *Jayt*. *Pech kelle*, Wern.

This substance is hard, solid, compact, and susceptible of a bright polish; it is opaque and of a pure black colour; its fracture is undulated, and sometimes shining like that of pitch. Specific gravity 1.259. It is said to be sometimes lighter than water; but Brongniart thinks this property rather belongs to the following variety.

Is found in strata of little thickness, in marly, stony, calcareous or gritty beds. It sometimes exhibits the organical texture of wood.

It is found in France; in Provence, at Beaufort in the Pyrenees; in the department of the Aude, near the village des Bains, six leagues to the south of Carcassonne (this sometimes contains amber), and near Quilhan, in the same department, in the communes of Sainte Colombe, Peyrat, and Balthie; it is situated at the depth of ten or twelve yards, in oblique strata between strata of sandstones; but these strata are neither pure nor continuous. Jet proper to be worked is found in masses, the weight of which is seldom 55 pounds. These mines have been wrought for a long time, and have produced a considerable quantity of jet, which was cut and polished in the same country. It also occurs in Germany, near Wittenberg in Saxony, where it is also cut and polished. Very fine jet has also been found in Spain, in Galicia, and the Asturias. Is likewise said to occur in Iceland, in the western part of the island.

Besides these, professor Janfson has quoted the following localities of pitch-coal or jet lignite: the coal districts of the Lothians,

LIGNITE.

Lothians, Fifeshire, Linlithgowshire, Island of Skye, and Caenoby and Sanquhar, in Dumfriesshire, in Scotland; Newcastle, Tindelfelt, Bolton and Whitehaven, in England; Austria; Hungary, Bannat, Transylvania; Upper Lusatia; Silesia; mountain-Neßthier in Hesse; Württemberg; Prussia; Bohemia; Salzburg; Italy; Prussia.

Of this combustible ornaments are made, particularly mourning trunks; it is piled with water on a horizontal wheel of sandstone. Jet mixed with pyrites is generally rejected.

2. *Fossil Lignite; Moor coal; Moor lobb.* Wern.

This variety occurs in thick and extensive beds. It is of a deep black, but less shining than that of the preceding variety. Its great friability is particularly characteristic of it. Its surface is always cracked, and its masses divide with the greatest facility into a number of cubic fragments; a character which is not found in jet.

Friable lignite is more abundant and consequently more useful than the two first varieties. It is found in horizontal banks often thick and extensive, but is never seen in such large masses as coal, with which it has been confounded by some; it differs not only by its properties but also by its geognostic situation. It occurs in those masses of sand which often fill up valleys in calcareous mountains, or cover the sides of the hills that skirt them. Is also found, though more rarely, in clayey marls.

Friable lignite is pretty common in the south of France, such as in the department of Vaucluse. Also as considerable masses at Lunette, department des Forêts.

Other localities cited by authors are Leitmeritz, Saatz, and Ellenbogen in Bohemia; Thütern near Krems in Austria; Transylvania; Moravia; the island of Bornholm in the Baltic, and the Faroe islands. It occurs more frequently in Bohemia than in any other country. Jam.

It burns without difficulty, but spreads a very disagreeable odour. It can be made use of only in manufactures, or to burn lime. Smiths cannot use it in their forges.

3. *Fibrous Lignite; Bituminous wood; Bituminifera lign.* Wern.

Its colour varies from a clear blackish-brown to clove brown; it has a perfectly woody form and texture; consequently, its longitudinal fracture is fibrous, and its transverse fracture shews the yearly layers of the wood. It is more easily frangible than wood, and takes a degree of polish which is cut with a knife.

This lignite often occurs in large masses.

It is found in France, in the vicinity of Paris, near St. Germain, in the life of Chanton, which appears to be entirely formed of it; and near Vitry on the banks of the Seine, where is a thick bed of trunks of trees well preserved. In the department of Ariege, the clefts of this lignite are filled with calcareous spar. In Liguria, near Cuneo, near the mouth of the Magra, it is found in thick and extensive beds. In Illin, in the mountains of Aulberg, the stratum is above two yards thick. At Steinberg, near Minden in Hanover, it forms two strata, one of about ten yards, the other of six, separated by a bed of rock from ten to fourteen inches thick. In England, at Bury near Exeter, there are fourteen pretty thick strata, situated at a depth of about twenty-two yards under sand and a part of clay. In Iceland, where it is very abundant, it is called *undinnud*; the trunks which form the beds are not decayed, and appear merely to have been compressed.

To these varieties we add the following from Jamieson: 1. *Black lignite*, in the Bantz-trap formation, accompanied with pyrites, in the island of Skye; in separate pieces in the gneiss in the island of Canary; in siltstone, in

the island of Skye, and in the independent coal formation in the county of Mid Lothian; Bohemia, in the Saatz and Leitmeritz circles; Austria; Transylvania; Moravia; Leoben in Styria; Irtenberg in Bavaria; Upper Palatinat; Landeck in Silesia; Halle; Meissen; Eisenach and Eisleben in Thuringia; Kalten-Nordheim near Fulda; Wehrau, Upper Lusatia; Württemberg; Freywalde and Könnigsvalde in Brandenburg; Wittenberg; Salzburg; Rotteln.

But this lignite is still more common in France, in the masses; it sometimes accompanies the preceding varieties; sometimes it is found in the strata, in the sides of banks of clay or sand. It is more abundant every where, and is used as fuel in the places where it is abundant.

This combustible being scarcely decomposed, and is rather vegetable than mineral, would not deserve to constitute a variety in a system of mineralogy, if it did not pass by imperceptible degrees into the preceding varieties, and into that which follows.

4. *Earthy Lignite; Earth coal; Erd lobb.* Wern.

Commonly called earth of Cologne, and sometimes, though improperly, *under*; but the true under, which comes from Italy or the east, contains nothing that is combustible, whence it cannot belong to this species.

This substance is black, or blackish-brown mixed with reddish. Its fracture and aspect are earthy; it is fine-grained, easily frangible and even friable; it is rather soft to the feel. Its specific gravity is nearly that of water. It burns, emitting a disagreeable smell.

It not only often contains vegetable remains, but sometimes itself pretends the texture of wood, without ever possessing either the colour and lustre, or the hardness of the preceding varieties. It burns sufficiently well to be used as fuel. It gives a gentle and equal heat.

It is found in secondary formation in the neighbourhood of coal mines, and more frequently in alluvial land.

As an authentic example of this variety may be mentioned the earthy lignite from the vicinity of Cologne, known in trade by the name of earth of Cologne. It is dug up at a little distance from that city, near the villages Trüffel and Liblar, where it forms very extensive beds of eight or ten yards in thickness, which are situated under elevated ground. It is immediately covered with a bed, more or less thick, of rolled pieces of quartz and Jasper, of the size of an egg, and rests on a bed of white clay of an unknown thickness. The bed of lignite is homogeneous, but fossil vegetables are found in it in a good state of preservation: they are, 1. trunks of trees lying one on the other without order; the wood is black or reddish, generally compressed, it readily exfoliates by drying in the open air. Some of these belong to dicotyledonous trees, others are fragments of palms. Among these M. Cuvier-Montbret has found some that are filled with a number of small round pyritic bodies resembling grains of small shot. Similar small, but elongated round grains, resembling a two-seeded pod, have been found by Mr. Heim, in the lignite of Kalten-Nordheim. The wood burns very well, and even with a small flame. 2. Woody remains of the size of a nut, and which are considered as belonging to a species of arca. The lignite of Cologne contains about twenty per cent. of ashes rather alkaline and corrosive. Its uses are manifold: it is worked in open air with a simple spade, but in order to convey it with greater convenience, it is sometimes made into vessels which give it the shape of a truncated cone. It is generally used as fuel in the neighbourhood of Cologne. It burns slowly but readily and without flame, like fungus timber, giving a large heat and leaving very fine ashes. The latter being considered as a very good name, a page

of the lignite is burnt on the spot where it is wrought, for the sake of obtaining them.

The earth of Cologne is particularly employed for painting in distemper and even in oil painting. The Dutch use it to adulterate snuff, and if it is not added in too great a quantity it gives the snuff a definable fineness and softness, and cannot be in the least injurious. — *Barthes*.

This lignite is found to occur also in Hesse, Bohemia, Saxony, Iceland, &c.; but as there has been a confusion between this lignite and the variety of ochre called *umbr*, we cannot be certain that these indications of localities are referable to earthy lignite.

It may have been observed, from what has been said on the situations peculiar to some varieties of lignite, that this fossil combustible belongs to depositions of the most recent formation, since it is found only in alluvial sand or clay; it seldom or never occurs in stony depositions, except in coarse grained lime stone and under basalt. In the mountains of Hesse called the Ringe Kühle, several thick beds of lignite are seen resting on sandstone, and separated by beds of potter's clay and sand. — (*Möhs*). On the sea-shore near Calais, fragments of lignite have been found that were penetrated by very transparent globularly aggregated quartz crystals.

The air which circulates where lignite is wrought is generally bad.

From what has been said it appears (our author concludes) that lignite is of a very different formation from that of coal; indeed, Mr Voigt thinks that there is no transition between these two substances.

The first of Brongniart's varieties of lignite, is by Werner given as a sub-species of his schwarz köhl, or black coal.

A variety not mentioned in the above account of lignite, but nearly related to the fibrous lignite No. 3, is the sub-species of Werner's brown-coal, called *common brown-coal*. Its colour is light brownish-black, passing into blackish-brown. It occurs massive. Its fragments are indeterminate angular, more or less sharp-edged. It is found at Bovey, and several other places mentioned under the localities of fibrous lignite or bituminous wood.

LIGNON, in *Geography*, a town of France, in the department of the Marne; 9 miles S. of Vitry le François.

LIGNUM ALOES, or *Wood of Aloes*. See ALOES.

LIGNUM Balsam. See BALSAM.

LIGNUM Campechianum. See LOG-WOOD.

LIGNUM Cassia. See CASSIA.

LIGNUM Colubrinum. See SERPENTINUS. Garcias tells us of the wonderful effects of this drug against the bites of venomous serpents, and describes two kinds of the plant which produces it; one having leaves like the pomegranate, and the other like the peach-tree; these, he says, both grow in the island of Ceylon; and Acoita mentions two other species of plants producing this wood, both different from either of those described by Garcias, and both growing in Malabar. We have also accounts in the *Geographus Nubensis* of another *Lignum colubrinum*, different from these, growing in Ethiopia, and possessed of the same virtue against the bites of serpents as the others. This last is called in the Arabic *haud al-ahab*, the plain verbal translation of which is snake-wood, or lignum colubrinum. He tells us, that it has some resemblance in form to pyrethrum, and that the wood is always contorted.

Alba carirka is another of its Arabic names, and this is the word by which Avicenna, and the other Arabian writers, interpret the *pyrethrum* of Dioscorides; but it is not certain whether the similitude of sounds between two or more Arabic words, may not have occasioned some confusion or

error here. *Dicarcarchus*, in his fragment of mount Pelion, describes the root of a tree growing there, which is not only a sovereign remedy for the bites of serpents, but even destroys them by its smell. This is also a lignum colubrinum; but whether the same with any of the others, or different from them all, we have not descriptions enough to determine.

It appears, upon the whole, that little can be depended on in the accounts of the medicine called lignum colubrinum by any author, unless he has had it experimented what he relates, and described the plant which produces the drug; for much imaginary virtue has been at all times given to many things against the bitings of serpents, and the lignum colubrinum of one author is not the lignum colubrinum of another.

LIGNUM Nephriticum. See NEPHRITIC.

LIGNUM Vitæ, the wood of a genus of trees, called by botanists *thuya*; which see.

Lignum vitæ is much valued by turners: making extremely beautiful cups, bowls, boxes, and other curiosities.

Lignum vitæ is also a name given to guaiacum.

LIGNY, in *Geography*, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Bar-le-Duc. The place contains 2815, and the canton 10,081 inhabitants, on a territory of 192½ kilometres, in 16 communes.

LIGNY-le-Château, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Auxerre; 9 miles N.E. of Auxerre. The place contains 1249, and the canton 7301 inhabitants, on a territory of 182½ kilometres, in 15 communes.

LIGOR, a town of Asia, and once capital of a kingdom, now subject to Siam, situated on a river of the same name. Here the Dutch have a factory for tin, rice, and pepper. N. lat. 8° 18'. E. long. 100° 35'.

LIGON, or *Tantalum*, an island at the entrance of the gulf of Siam, triangular in its figure, and about 130 miles in circuit. N. lat. 8° 10'. E. long. 100° 50'.

LIGUA, a river of Chili, which runs into the Pacific ocean, S. lat. 32°. — Also, a town of Chili, on this river; 72 miles N.N.E. of Valparaíso.

LIGUET, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Loches; 9 miles S.W. of Loches. The place contains 1028, and the canton 9756 inhabitants, on a territory of 327½ kilometres, in 14 communes.

LIGUNY, a town of Samogitia; 44 miles E. of Miedika.

LIGULA, a word used by medical writers in very different senses. Some express by it the clavicle, others the glottis; others use it as the name of a measure, for things either liquid or dry, being a quarter of a cyathus, equal to a forty-eighth part of a pint with us; others finally use it for a weight, less than half an ounce by two scruples, or ten scruples.

LIGULA, in *Natural History*, a genus of the mollusca order of the class Veneres, according to the Linnæan system; the character of this genus is body linear, equal, long; the fore part obtuse, the hind part acute, with an impressed dorsal suture. There are only two species, viz. 1. the *intestinalis*, which has a clear white, and very narrow body, and which is found in the intestines of the merganser and guillemot; about a foot long, and exactly resembling a piece of tape. 2. The *abdominalis*, of which there are several varieties; the body is of a pale ash colour, and rather broad; it is found in the abdomen of the loche, gudgeon, tench, crucian, dace, bleak; cyprinus vimba, and bream. These ani-

mals are found chiefly in the mesentery, emaciating the fish they infest, and making them grow deformed: when they escape from the body they penetrate through the skin; they are sometimes solitary and sometimes gregarious, about one-twentieth of an inch thick, and from six inches to five feet long.

LIGULATE FLORETS, in *Botany*, from *ligula*, a small strap, are such as compose the radiant part of a daisy. See **FLORET**.

LIGURES, in *Ancient Geography*, a people of Gallia Cisalpina, who occupied a territory along the sea-coast, bounded on the N. by the Po, and separated from Gaul by the Alps, and the oblique winding course of the Varus. Its eastern limit, at different periods, was the Macra, and the rapid Arnus. It comprehended the greater part of the districts of Nice, Piedmont, Montferrat, Genoa, Modena, and Parma. This powerful nation was composed of many tribes, the boundaries of whose settlements cannot now be ascertained with precision. These tribes were the Vediantii, who inhabited a mountainous tract watered by the Varus, in which were Nicca or Nice, and Cemenelum, or Cimia; the Intemelii, who occupied several places along the sea-coast, viz. Intemelium, or Ventimiglia, Tropæa Anguati, or Torbia, &c.; the Ingauni, whose capital was Albingaunum, or Albenga, and they also occupied the sea-port towns of Vada Sabatia, or Vau, and Savo, now Savona; the Epanterii, who inhabited a mountainous district between the Vaugienni and Ingauni; the Vaugienni, who resided near the declivity of Mons Vesulus, mount Viso, and the sources of the Po; the Statielli, who were stationed at the bottom of the gulf of Genoa, in a hilly territory, that extended northward to the Tanarus; the cities and towns in this district, occupied by the Statielli, and other inferior tribes of the Ligures, were Genua or Genoa, Portus Delphinus, or Porto Fino, Segestria or Selti, Portus Veneris, or Porto Venere, and Luna; and the principal rivers of this district were the Macra and Boates; the inland towns in the territory of the Statielli were Aquæ Statiellæ or Aquæ, Ceba or Ceva, near the source of the Tanarus, Pollentia, Alba Pompeia, Alta or Alti, Bodincomagus or Indultra on the Po, Forum Fulvii, furnished Valentium, on the Po, Caristum, Dertona or Tortona, and Iria or Voghera. The Celates and Cerdicates inhabited an inconsiderable district between the Trebia and the Po, now called Pavese; their principal towns were Clatidium, Chiallezo, and Litubium. The Brinates occupied a hilly tract not far from the sea-coast, watered by the Boates. The chief town of the Apuani was Apua, now Pontremoli, at the foot of the Apennines, near the source of the Macra. The Ananes, or Anamani were for some time established in the territory now called Parma and Modena; the Lingones, in the northern part of Bolognese, and in Ferrara; the Baii, in the S. part of the Bolognese, at the foot of the Apennines; the Senones, in the estate of the church, along the coast of the Adriatic from Rimini to Ancona. To those tribes belonged the following towns, viz. Parma, Braxellum or Berseello, Forum Novum or Fornovo, S.W. of Parma on the Taro or Taro, Tanetum or Tanedo, between Parma and Modena, Calicaria, S. of the Po, Padinum or Buondena, N.W. of Forum Aheni, now Ferrara, Hadrianum or Ariano, between above the mouth of the Po, and Spina at the mouth of the fourth branch of the Po. The following towns were situated on Via Æmilia, between Parma and Ariminum, viz. Tanetum already mentioned, Regium Lepidi or Reggio, Mutina or Modena, Bononia now Bologna, Claterna or Claterna, New Quaderno, Forum Corneli or Imola, Faventia or Faenza,

Forum Livii or Forli, Forum Popilii or Forlimpopoli. The inland settlements were Sufemontium, Aquinum, and Ravenna.

LIGURIA, a country of ancient Italy, which had on the W. a part of the Maritime Alps, and the river Varus; on the N. the Po; on the E. a part of Gallia Cispadana, and a small portion of Etruria. In the time of Scythax, who wrote about the year 350 B.C., the Ligurians extended themselves to the Arnus. See the preceding article.

LIGURIAN REPUBLIC. See **GENOA**.

LIGURINUS, in *Ornithology*, a name used by many authors for the bird more commonly known by the name of *spinus*, and called in England the *skylark*.

LIGURIUS, in *Jewish Antiquity*, a precious stone on the high priest's breast-plate. It is called *leſchem* in Hebrew. Theophrastus and Pliny describe the ligurius to be a stone like a carbuncle, of a brightness sparkling like fire.

The ligurius was the first stone in the third row upon the high priest's pectoral, and the name of God was inscribed upon it. Ælian, De Animal. lib. iv. cap. 17. Pliny, lib. viii. cap. 38, and lib. xxxvii. cap. 3. Calm. Dict. Bibl. See **LYNCERIUS Lapis**.

LIGUSTICUM, in *Botany*, *Aquilegia* of Dioscorides, so called from Liguria, in Italy, its native country. The ancient plant evidently appears by the description of this author to have been of the umbelliferous tribe, growing in mountainous situations, and of an aromatic purgative nature. So far it agrees with the Linnæan adaptation of the name; but among so intricate a tribe, who shall say that the *Ligusticum* of Linnæus is, or is not, the very same with that of Dioscorides? Linn. Gen. 137. Schreb. 187. Wild. Sp. Pl. v. 1. 1424. Mart. Mill. Dict. v. 3. Sm. F. Brit. 309. Prodr. Fl. Græc. v. 1. 103. Ant. Flor. Kew. ed. 2. v. 2. 141. Juss. 222. Tourn. t. 171. Lamarck. Illustr. t. 198. Germ. t. 85. (Cientaria; Tourn. t. 171. Denaa; Allion. Pedem. v. 2. 34. t. 63.) - Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellifera*.

Gen. Ch. *General umbel* of numerous ray; *partial* similar to it. *General involucrium* membranous, of about seven unequal leaves; *partial* of scarcely more than four, likewise membranous. *Perianth* of five teeth, scarcely discernible. *Cor.* *Universal* uniform; flowers all equally fertile; *partial* of five equal, involute, flat, undivided petals, keeled inwardly. *Stam.* Filaments five, capillary, shorter than the corolla; anthers simple. *Pist.* Germen inferior; styles two, close together; stigmas simple, obtuse. *Peric.* Fruit oblong, angular, furrowed, separable into two parts. *Seeds* two, oblong, smooth, marked with three elevated lines on the outer side, flat on the other.

Ess. Ch. Fruit oblong, with three ribs on each side. Flowers uniform. Petals involute, regular, undivided. Calyx of five teeth.

Obs. Reichard observes that some male flowers are occasionally intermixed. The fruit has not five grooves or furrows, but three elevated ribs, at each side.

1. *L. officinarum*. Common Lovage. Linn. Sp. Pl. 340. Woodv. Med. Bot. t. 102. Zorn. Ic. t. 133. Ehret. Pl. Off. 303. (Laciniatum vulgare; Ded. Penz. 311. Germ. 1028. Morif. Sect. 9. t. 3. p. 1.) Leaves repeatedly compound; leaflets wedge-shaped at their base, unequally cut in the fore-part. Umbels many together. Native of the Ligurian Alps, whence it is taken for the *L. officinarum* of Dioscorides. In medico-botanical gardens it is preserved on that account, but rarely elsewhere. The root is perennial, requiring a rich, rather moist soil. *Height* five feet high, of a light, rather glaucous, green, smooth, strongly aromatic

and

and acrid. *Leaves* bipinnate; leaflets about two or three inches long, and one broad, deeply cut. *Umbels* aggregate, stalked, their involueral leaves deflexed, whitish. *Flowers* small, yellowish, coming out in May and June.

This plant, especially the root, "whose flavour is less ungrateful (says Dr. Woodville) than the leaves," abounds with a yellowish fetid gum resin. It was thought to be useful in removing obstructions of various kinds, and even to assist delivery; but is now laid aside.

2. *L. scoticum*. Scottish Lovage. Linn. Sp. Pl. 359. Tagl. Bot. t. 127. Fl. Dan. t. 207.—Leaves twice ternate, dilated, deeply serrated.—Native of sea-shores in Sweden, Canada, Scotland; and recently discovered, as Mr. Wench informs us, at Dunsinborough castle, Northumberland. It is of much humbler growth than the first species, with twice ternate, broader and rounder leaves, shining beneath, rather serrated than cut. *Umbels* fewer, white with a reddish tinge. Mr. Lightfoot says this is eaten raw as a salad, or boiled as greens, in the isle of Skye, where it is called *Sianis* or *Sianis*. The root is reckoned a good carminative, and an infusion of the leaves in whey serves to purge calves.

3. *L. nolydium*. Nettle-leaved Lovage. Villars Dauph. v. 2. 608. t. 15. (Smyrniun nodiflorum; Allion. Pedem. v. 2. 21. t. 72. Angelica alpina, ad nodos florida; Tourn. Ind. 313.)—Leaves twice or thrice ternate, dilated, taper-pointed, strongly serrated. Umbels very numerous. Flower-stalks whorled, widely spreading.—Native of shady pine-forests on the Alps. Stem three or four feet high, foliary, with very numerous, whorled, divaricated, slender flower-stalks, and copious white umbels, whose involueral leaves are very few and narrow. Radical leaf foliary, large, smooth, twice or thrice ternate, or somewhat pinnate; the leaflets two or three inches long, ovate, taper-pointed, strongly serrated in the manner of a nettle. Villars says the root is sold at Lyons by the name of Bohemian Angelica, and has an aromatic flavour, less agreeable but more lasting than that of the true Angelica. It is distinct, as Villars well observes, from the *Angelica verticillaris* of Linnaeus, and appears never to have come under his observation.

4. *L. peloponense*. Hemlock-leaved Lovage. Linn. Syst. Veg. ed. 14. 283. (L. peloponnesiacum; Linn. Sp. Pl. 360. Jacq. Austr. 33. append. t. 15. Sefeli peloponense; Camer. Epit. 514. Matth. Valgr. v. 2. 112. Cicuta latifolia fetidissima; Ger. em. 1062 Morif. Sect. 9. t. 6. f. 5.)—Leaves repeatedly pinnate; leaflets lanceolate, decurrent, taper-pointed, cut.—Native of mountainous woods in Carinthia, Rhætia, Switzerland, and, as it should seem, in the Peloponnesus; but Dr. Sibthorp did not find it. In gardens it is conspicuous, but too much like hemlock to be cultivated for ornament. The leaves are very large, but finely cut, of a fine shining green, their segments numerous, crowded, remarkably decurrent and taper-pointed. Umbels white, one very large, with several smaller in whorls, accompanied by leaves, at the base of its stalk.

5. *L. austriacum*. Aulrian Lovage. Jacq. Austr. t. 151. Allion. Pedem. v. 2. 15. t. 43. (L. n. 11; Gmel. Sib. v. 1. 176 t. 45.)—Leaves twice pinnate; leaflets wedge-shaped, decurrent, cut. Umbels leafy.—Native of the Alps of Austria, France, Italy, &c. Much like the last, but the stem is stouter; umbels larger and more leafy; leaves not so regularly pinnate or pinnatifid, nor so exactly decurrent, neither are they by far so taper-pointed.

6. *L. cornubiense*. Cornish Lovage. Linn. Sp. Pl. 359. Sm. Fl. Brit. 310. Ic. Pin. t. 11. Engl. Bot. t. 683. (L. aquilegifolium; Willd. n. 3. L. alterum belgarum;

Lob. Ic. 786. Danae aquilegifolia; Allion. Pedem. v. 2. 34. t. 63. Smyrniun lufitanicum minus, apii foliis; Tourn. Inst. 316.)—Radical leaves twice compound, wedge-shaped, cut; stem-leaves ternate or simple, lanceolate and entire. Seeds ovate, tumid, obscurely ribbed.—Native of bulky stony places in Cornwall, Piedmont, and Portugal. Gathered by Dr. Sibthorp on mount Athos. It is perennial, and known from all the rest by its principal compound leaves being all radical, the stem bearing only a few ternate or simple ones, quite undivided. The umbels are few and solitary. Involucrium scarcely membranous. Seeds remarkably tumid, ovate, black, obscurely ribbed.—This plant, found in Cornwall in the time of Dillenius, who has figured it in his edition of Ray's Synops. t. 8, was long overlooked, and supposed to be lost, till it was recovered about 25 years ago. Specimens sent by Prof. Allion to the writer of this have proved his Danae to be the same. (See DANAEA.) Little did the late Prof. Sibthorp suspect he had found so celebrated an English plant on mount Athos, which from his herbariana proves to be the case. Willdenow perhaps learnt from the Essay on Dorsiferous Ferns, Mem. de l'Acad. de Turin, v. 5. 420, that it was a Ligusticum, but having never seen it, either as the Danae or the Cornish Lovage, he has it twice in his Sp. Pl.

7. *L. pyreneum*. Pyrenean Lovage. Willd. n. 8. Goum. Illustr. 14, but not his t. 10. f. 2, which, though cited by himself, and copied by others, is *Thapsia garganica*. (L. alpinum perenne, ferulae folio, floribus a bis; Segoe. Veron. v. 2. 41. t. 13.)—Leaves repeatedly compound; leaflets pinnatifid; segments nearly linear, awned. General involucrium slight. Seeds oblong, with membranous even ribs.—Native of the south of France about the Pyrenées; also of mount Baldus, near Verona. The leaves are large, very finely divided, light green; their segments inclining to elliptical, decurrent, obtuse, with a minute bristle. Stem leafy. Umbels rather large; the general involucrium wanting, or deciduous; when present it is sometimes of one three-cleft leaf. Flowers white, small. Fruit elliptic-oblong, with straight, pubescent, membranous ribs, and crowned with but a small slender floral receptacle. Styles reflexed.—Linnaeus confounded this with his *Selinum Carvisfolia*, but they appear to be sufficiently different.

8. *L. multifidum*. Five-leaved Lovage. (L. foliis triplicato-pinnatis, extremis lobulis breviter multifidis; Gmel. Sib. v. 1. 190 t. 46. Herb. Linn.)—Leaves thrice compound; segments linear, channelled, decurrent, pointed. Seeds ovate, with membranous, somewhat crisped, ribs.—Native of fields in the province of Nét, in Siberia. Gmelin's specimen is in the herbarium, but appears never to have been noticed in the works of Linnaeus. The root is said to have the taste and shape of Carrot; it is as thick as the middle finger at the top, long and taper downward, yellowish without, white within. Stem two cubits or more in height, hollow, branched from about a third part of its height upward, the branches a foot long, somewhat leafy. Radical leaves with their long stalks about a span long or more, finely thrice compounded, the segments uniformly narrow, acute, scarcely awned, channelled, entire, all decurrent, light green, smooth: stem leaves much less divided, and smaller. Umbels not large, white; their general involucrium of about eight lanceolate, membranous-edged, leaves, and the partial ones are similar. Fruit short and roundish, with crisped wings, and a very large floral disk or receptacle. Styles divaricated. Stigmas very obtuse.

9. *L. cardians*. Pale Lovage. Ait. Hort. Kew. ed. 1. v. 1. 348. ed. 2. v. 2. 142.—Leaves repeatedly compound;

leaflets wedge-shaped, cut, smooth. General involucre of two leaves, somewhat leafy. Ribs of the seeds membranous, smooth.—Introduced into Kew garden about the year 1780. It is said to be a hardy perennial, flowering there in July and August; but its native country is unknown.

10. *L. peregrinum*. Parsley-leaved Lovage. Linn. Sp. Pl. 360. Jacq. Hort. Vind. v. 3. p. 13. t. 18.—Leaves repeatedly compound; leaflets three-cleft, wedge-shaped, cut. Seeds ovate, obscurely ribbed. Umbels terminal.—Native of Portugal; gathered by the late M. Broussonet on the rock of Gibraltar, flowering in May. The root is biennial. The whole plant has the appearance, even the taste and smell, of common parsley, but is in every part stouter and more rigid. There can be no doubt of its close affinity to that plant; and great violence is offered to nature in referring one to *Ligusticum*, the other to *Apium*. Yet even the Bauhins distinguished them as species.

11. *L. diffusum*. Spreading Lovage. Roxburgh MSS.—Leaves twice compound; segments wedge-shaped, decurrent, three-toothed. Seeds ovate, strongly ribbed. Umbels on lateral stalks, opposite to the leaves.—Native of the East Indies; given by Dr. Roxburgh, with the above name, to lord viscount Valentia, to whom we are obliged for the specimen. Its habit is so like the last, the fruit being of the same shape, though more strongly ribbed, that it confirms the genus of that species. It differs in having smaller, less compounded, and blunter neatly toothed leaves, strongly decurrent in their segments, and umbels on solitary, simple, lateral stalks. The involucre leaves are of a sufficient number, lanceolate, long, narrow, pointed, with membranous edges. Ribs of the seeds prominent and somewhat crisped, not membranous.

12. *L. Meum*. Brittle-leaved Lovage, Spiguel, Meum, or Bald-money. Crantz. Aultr. fasc. 3. 82. Roth. Germ. v. 1. 123. v. 2. 322. (*Meum athamanticum*; Jacq. Aultr. v. 4. 2. t. 303. Sm. Fl. Brit. 308. Engl. Bot. t. 2249. *Athamanta Meum*; Linn. Sp. Pl. 353. Hudf. 116. *Ethusa Meum*; Linn. Syst. Veg. ed. 14. 287. Willd. Sp. Pl. v. 1. 1447.)—Leaflets all in numerous, deep, brittle-like segments.—Native of mountains in Italy, Spain, Germany, Switzerland and Britain, flowering in May. The propriety of referring it to this genus was hinted in Fl. Brit. and Crantz and Roth had previously so arranged it. Where so many different opinions have been started, the genus cannot be supposed very clear, but we venture to remove the plant hither. Its root is powerfully aromatic, with a flavour like melilot, of which the herb partakes; and an infusion of the plant is said to give cheese the taste of the Swiss *Chapelle-gar*. The finely divided leaves distinguish it readily. The flowers are white, with a blush occasionally. Fruit oblong, often curved, coloured; its ribs strong, not membranous, even, not crisped.

13. *L. balearicum*. Balearic Lovage. Linn. Mant. 218.—Radical leaves pinnate, rounded, serrated; the lower leaflets auricled; stem-leaves pinnate, narrow, cut. Fruit oblong.—Native of the Balearic islands, as well as of Italy and Spain. M. Broussonet gathered it at Gibraltar in May. Linnaeus had this plant in the Upsal garden, but says it did not ripen seed, so that he was doubtful of the genus. It appears to us rather to belong to *Athamanta*. The young fruit is striated rather than ribbed; the involucre leaves very slender, awl-shaped, not membranous. The leaves have somewhat of the aspect of *Pastinaca sativa* in a wild state. The umbels are wide, but slender, yellow.

14. *L. Gingidium*. New Zealand Lovage. Forst. Prod. 22. Willd. n. 12. (*Gingidium montanum*; Forst. Gen. 21.)—Leaves pinnate; leaflets ovate, crenate; oblique and

entire at the base.—Native of New Zealand. Its aspect is not unlike *Stium angustifolium*, but the umbels are axillary or terminal, and the leaflets very finely, rather sharply, crenate, all broad and ovate.

15. *L. longifolium*. Long-leaved Lovage. Willd. n. 13.—“Leaves twice ternate; the radical ones doubly compounded; leaflets linear-lanceolate, entire.”—Native of Siberia. Prof. Willdenow saw a dried specimen. We know this species by his account only. He cites the *Pseudanum majus italicum* of Morison, sect. 9. t. 15. f. 1, (at the bottom,) as seeming to agree with his plant.—The leaflets are stalked, linear, entire, tapering at each extremity, six or seven inches long, and three lines wide. General involucre wanting; partial of many fetaceous leaves.

We have, in the above view of the genus *Ligusticum*, added three species to his list, although we have reduced two of his into one.

LIGUSTICUM, or *Common Lovage*, in the *Materia Medica*. The odour of this plant is very strong, and peculiarly ungrateful; its taste is warm and aromatic. It abounds with a yellowish, gummy, resinous juice, very much resembling opoponax. Its virtues are supposed to be similar to those of angelica and mallow-wort in expelling flatulencies, exciting sweat, and opening obstructions; and it is therefore chiefly used in hysterical disorders and in uterine obstructions. A teacup-ful of the juice with Rhenish wine, or a decoction of the seeds with wine or mugwort water, was, by Forestus, said to be a secret remedy of extraordinary efficacy in slow or laborious parturition. The leaves, eaten as salad, are accounted emmenagogue. The root, less ungrateful than the leaves, is said to possess similar virtues, and may be employed in powder. Woodv. Med. Bot.

LIGUSTICUM Marmor, in *Natural History*, a name by which some authors have called the *Carrara marble*, the *marmor lunense* of the ancients. It is a fine white marble, harder than the Parian or statuary kind, and used for tables, chimnies, &c. as the other for carving. See **LUNENSE Marmor**.

LIGUSTRUM, in *Botany*, a name found in Pliny and other Latin writers, by which the oriental Cypros (*Lazofonia inermis*) seems originally to have been intended, but which is now universally received for our Privet.—Linn. Gen. 9. Schreb. 12. Willd. Sp. Pl. v. 1. 41. Mart. Moll. Dict. v. 3. Sm. Fl. Brit. 12. Ait. Hort. Kew. ed. 2. v. 1. 19. Tournef. t. 367. Juss. 106. Lamarck Illustr. t. 7. Gaertn. t. 62.—Class and order, *Diambris Monogynia*. Nat. Ord. *Sepiaria*. Linn. *Jasminae*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, very small; mouth four-toothed, erect, obtuse. Cor. of one petal, funnel-shaped; tube cylindrical, longer than the calyx; limb spreading, cut into four ovate segments. Stam. Filaments two, opposite, simple; anthers erect, almost as long as the corolla. Pist. Germen superior, roundish; style very short, stigma cloven, obtuse, thickish. Peric. Berry globose, smooth, single-celled. Seeds four, convex on one side, angulated on the other.

Obf. Gaertner more correctly describes *Ligustrum* as having a two-celled berry; the cells coated with a thin membrane, having two seeds in each cell.

Ess. Ch. Corolla four-cleft. Berry superior, of two cells, with two seeds in each cell.

1. *L. vulgare*. Privet. Linn. Sp. Pl. 10. Engl. Bot. t. 764. Curt. Lond. fasc. 5. t. 1.—Leaves elliptic-lanceolate, obtuse, with a little point.—Not uncommon in hedges and thickets where the soil is moist and gravelly, flowering in May and June, and ripening its berries in August.—This shrub rises to the height of five or six feet. *Br. incl.* wood-

like. *Leaves* opposite, nearly sessile, dark green, smooth, lanceolate, (now and then elliptical,) entire, pointed, not acuminate, generally remaining through the winter. *Panicles* terminal, dense. *Flowers* white, smelling disagreeably. *Berries* dark purple, or blackish, very bitter, like the foliage and bark.

Privet is remarkable for thriving amidst the smoky atmosphere of towns, being frequently planted for hedges in gardens, for which purpose it is particularly eligible, since its foliage somewhat resembles that of the myrtle, and in mild winters is almost evergreen. It was formerly known by the name of Print, or Prim-print, most probably from its neat and regular appearance when clipped and trimmed. The best mode of propagating this plant is by seed. It is eaten by the *Sphinx ligustri*, in its caterpillar state, one of our finest native insects. Curtis says that the berries are recommended in dyeing, colouring of wines, and as affording a purple colour to stain prints, though at the same time he remarks there are much better materials in common use for the same purposes.—This species is subject to variation with respect to its leaves, which are sometimes variegated, and growing three at each joint. The berries have also been found white, or rather yellow. We ought not to omit mentioning that this fruit is one of the vegetable substances which has been suspected to form a principal ingredient in the present popular gout medicine, the *eau medicinale d'Huffn.*

2. *L. japonicum*. Broad-leaved Privet. Willd. n. 2. Thunb. Japon. 17. t. 1.—Leaves ovate, acuminate. Panicle divaricated.—A native of Japan, as its specific name testifies; where it flowers in June and July, and ripens its fruit late in the autumn.—*Stem* eight or nine feet high, very much branched. *Branches* opposite, roundish, rugose, ash-coloured, erect, rather spreading. *Leaves* opposite, on footstalks, entire, with a deep furrow in their centre, green above, pale underneath, smooth, an inch broad, an inch and half long. *Footstalks* round, furrowed on the upper side. *Flowers* in terminal spreading panicles. *Berry* ovate, smooth, the size of a pea.

3. *L. lucidum*. Chinese Privet. Wax-tree. Ait. Hort. Kew n. 2.—Leaves ovate-oblong, acuminate, shining above. Panicle greatly divaricated.—A native of China, and introduced into Kew garden by the Right Honourable Sir Joseph Banks, K.B. in the year 1794. It flowers from July to September.—This *shrub* is only to be seen at the place above mentioned, where we are informed it makes a beautiful appearance, when covered with its copious white blossoms, in the open air. It is to be regretted that so desirable a plant should not be in general cultivation.

4. *L. sinense*. Narrow-leaved Privet. Loureir. Cochin. 19. Mart. Mill. Dict.—Leaves lanceolate, downy, panicles oblong, both lateral and terminal. Found near Canton in China.—This small tree, according to Loureiro, grows to the height of about eight feet. *Branches* diffuse, straight. *Leaves* opposite, lanceolate, entire, downy, dark-green. *Flowers* white, small, in oblong panicles. *Berry* very small, roundish, of a brown colour.

LIGUSTRUM, in Gardening, comprehends a plant of the hardy deciduous and evergreen shrubby kind; of which the species cultivated is the common privet (*L. vulgare*). It is a shrub, usually about six feet in height, branched, the bark of a greenish ash-colour, irregularly sprinkled with numerous prominent points; branches opposite, the young ones flexible and purplish; the leaves opposite, on very short petioles, smooth on both sides, perfectly entire, the lower ones at the bottoms of the small branches leaved: the panicle about two inches in length, close and somewhat pyra-

midal; branches and pedicels appearing villose when magnified; the corolla white, but soon changing to a reddish-brown; the flowers are sweet-scented; berry superior, fleshy, sub-globular, thinning, of so dark a purple as to seem black; it is found wild in most parts of Europe, &c. flowering in July, and the berries ripen in autumn.

Of these plants there are several varieties; as with the leaves in threes, and enlarged at the base; with silver-striped leaves; with gold-striped leaves, with white berries; and the evergreen or Italian privet, which rises with a strong stem, the branches less pliable, and grows more erect; the bark is of a lighter colour. The leaves much larger, ending in acute point, of a brighter green, and continue till they are thrust off by the young leaves in the spring: the flowers are rather larger, and are not often succeeded by berries in this climate.

Method of Culture. These different plants are capable of being increased by seeds, layers, suckers, and cuttings; but the first method affords the best plants: the seeds should be sown in autumn, in a bed of common earth an inch deep, or in drills the same depth; but as they do not always grow freely the first year, they may be buried till next autumn, in pot of sandy earth, in the ground, and then sown as above: when the plants come up they should be kept well weeded, and, when a year or two old, be planted out in nursery rows, to remain two or three years, then removed where they are wanted to remain: the layers should be laid down, from some of the pliable young branches, in the earth, in autumn or winter, when they will be rooted by the autumn following; then take them off from the stool, with their roots, and plant them in the nursery for a year or two, or till of a proper size for the purposes they are intended: the suckers which arise annually from the roots should be taken up in autumn, winter, or spring, with roots, and planted in the nursery as above; the cuttings of the young shoots, eight or ten inches long, should be planted in the autumn, in a shady border, where they will be properly rooted by the following autumn, when they may be planted out in nursery rows, to acquire proper growth, in the manner directed above. The varieties with striped leaves may be increased by budding, or marching upon the plain sort, or by laying down the branches; but they seldom shoot so full as to produce branches proper for this purpose: and being more tender, they should have a dry soil and a warm situation: in a rich soil they soon lose their variegation, and become plain. The Italian or evergreen sort, which is now generally found in the nurseries, is equally hardy with the other sorts, and thrives in almost any situation: it is increased in the same manner; but as it seldom produces berries in this climate, they must be procured from the place of its native growth.

These plants may be introduced in the shrubberies and other parts by way of variety, especially the evergreen sort.

But the chief use of the common sort is to form such hedges as are required in dividing gardens for shelter or ornament; yet the Italian or evergreen kind should be preferred; it bears clipping well, is not liable to be disfigured by insects, and having only fibrous roots, it robs the ground less than almost any other shrub; it is one of the few plants that will thrive in the smoke of large towns, though it seldom produces any flowers in the closer parts after the first year: it also grows well under the drip of trees and in shade; the *sphinx ligustri*, or privet hawk moth, and *phalena tyrin-garia*, feed on it in the caterpillar state, and *meloe vesicatorius*, *cantharides* or blister beetle, is found on it. From the pulp of the berries a rose-coloured pigment may be prepared;

pared; with which, by the addition of alum, wool and silk may be dyed of a good durable green: for which purpose they must be gathered as soon as they are ripe.

LIHONS, in *Geography*, a town of France, in the department of the Somme; 18 miles E. of Amiens. N. lat. $50^{\circ} 15'$. E. long. $2^{\circ} 31'$.

LIKA, a county and province of Dalmatia, or Austrian Croatia, bordering on the Adriatic, opposite to the island of Pago.

LIKAVA, a town and castle of Hungary; 5 miles N. of Rosenbergh.

LIKE QUANTITIES, in *Algebra*, are those which are expressed by the same letters, under the same power, or equally repeated in each quantity.

Thus $2b$ and $3b$, and $9ff$ and $3ff$, are like quantities; but $2b$ and $3bb$, and $9ff$ and $3fff$, are unlike ones, because the quantities have not every where the same dimensions, nor are the letters equally repeated.

LIKE Signs, or *Symbols*, are when both are affirmative, or both negative.

If one be affirmative, and the other negative, they are unlike signs.

Thus $+6d$ and $+5d$, have like signs; but $+9f$ and $-7f$, have unlike signs.

LIKE Figures, in *Geometry*, are such as have their angles equal, and the sides about those equal angles proportional. See SIMILAR.

LIKE Arcs, in the projection of the sphere in plano, are parts of lesser circles, containing an equal number of degrees with the corresponding arcs of greater ones.

LIKE solid Figures, are such as are contained under like planes, equal in number.

LIKENAS, in *Geography*, a town of Sweden, in the province of Warmeland; 60 miles N. N. W. of Philipstadt.

LI-KIANG-TOU, a city of China, of the first rank, in the province of Yun-nan, near the source of the river Yan-gong-kiang. This place is said to be occupied by descendants of some ancient colonies of Chinese; it has no other city under its jurisdiction, but the mountains that surround it separate it from the land of the Lamas. Its mountains are said to contain mines of gold. Amber and pine-apples are plentiful. The adjoining land is fertile, and is well watered. N. lat. $26^{\circ} 52'$. E. long. $100^{\circ} 8'$.

LILA, a town of Abyssinia, on the coast of the Red sea; 48 miles S. S. E. of Arkiko.

LILAC, in *Botany*, or rather *Lilik*, the Turkish name for the Privet, *Ligustrum vulgare*, according to Dr. Sibthorp; see Prodr. Fl. Græc. v. 1. 3. It is generally known in England as the appellation of the beautiful and popular *Syringa vulgaris*, which was introduced into our gardens, under the name of *Lilach*, or *Lillach*, in the time of queen Elizabeth; nor was this word by any means borrowed, as Dr. Johnson supposes, from the *Lilas* of the French, though they have, doubtless, one common origin. The close affinity and near resemblance between the Privet and the Lilac, leave no room for wonder at their having the same name among the Turks. The common as well as the Persian Lilac is cultivated by them, and the former at least is found wild in some countries under their dominion. Matthioli has given a fine cut of it (see *Lilac*, Matth. Vulg. v. 2. 575, 576.), from a drawing brought from Constantinople under this name; and it is curious to observe how the incorrect delineation of its fruit led him to mistake it for a plant of the Pistacia kind, and thence to suppose it a sort of *Glans Uguentaria*, or *Ben nut*.

LILÆA, in *Ancient Geography*, a town which, according to Homer, was not far from the springs of the Cephissus, in the Phocide. When the Macedonians took possession of it, Patron, one of the citizens, roused and armed the people, and caused them to evacuate it. In commemoration of this event, his fellow-citizens erected a statue to his honor in the town of Delphi. In the time of Pausanias it had a theatre, baths, and two temples, one in honour of Apollo, and another of Diana. The statues were formed of Pentelic marble.

LILBURNE, JOHN, in *Biography*, famous for his exertions in the cause of liberty during the tyrannies of Charles I. and Cromwell, was born in the year 1618, of an ancient family, in the county of Durham. At an early age he was sent, with very little education, to London, and put apprentice to Mr. Thomas Hewton, of London-stone, a wholesale clothier. He had, probably, imbibed those principles for which he was afterwards distinguished among his own relations in the country, and having a bold and intrepid mind, he was, from this period, involved in that perpetual series of contention and suffering, of which we shall proceed to give a brief account. The first display of his temper was exhibited in a complaint which he laid before the chamberlain of London, against his master for ill usage. He carried his point, and obtained redress, and ever afterwards not only lived in peace with him, but he says, in his "Legal and Fundamental Liberties, &c." that he had in Mr. Hewton "the truest friend that ever servant had of a master in the day of his trial." While he was in his apprenticeship he had much leisure time, which he spent in reading the bible, the book of Martyrs, and the works of Luther, Calvin, Beza, &c. From these he unquestionably imbibed an enthusiastic passion for encountering all dangers and sufferings in the cause of truth. In 1636 he was introduced to the acquaintance of Dr. Bastwick, at that time a prisoner in the Gate-house, whom he constantly visited, and for whom he contracted such a friendship and affection, that he could, he says, have readily laid down his life in his defence. He was soon engaged actively in the popular cause, and carried to Holland one of the doctor's anti-episcopal writings in order to get it printed. Shortly after his return he was apprehended, tried, and convicted in the star-chamber court of printing and publishing libels and seditious books. At his examinations he refused to answer the interrogatories of his judges, and in every instance he justified and maintained the rights and privileges attached to his character as an Englishman. He was sentenced on this occasion to receive 500 lashes, and then to be set in the pillory, which sentence was executed with great severity, the whipping being inflicted with knotted cords, as ordered by the bloody decree of old Sir Henry Vane. His spirit was not, however, subdued, for even on the pillory he uttered many invectives against the bishops, and threw pamphlets from his pockets among the crowd. For this conduct he was remanded to prison, and, according to his own account, endured a world of other unheard-of miseries and barbarous cruelties for three years together. Though double-ironed, and in one of the worst cells in the prison, he contrived while there to get another libel printed and published. Such was the opinion held respecting his desperate resolution, that a fine having taken place near the cell in which he was locked up, he was suspected of being the occasion of it, for the sake of obtaining his deliverance, and the other prisoners and neighbours joined in an application to have him removed, by which he obtained a more airy situation. On the meeting of the Long Parliament in 1640, he was allowed the liberties of the Fleet, an indulgence that enabled him to appear as a supplanter of

an armed mob which assembled at Westminster, and cried out for justice against the earl of Strafford, for which he was brought to the bar of the house of lords, on a charge of treason, but dismissed. In the following year the house of commons voted "That the sentence of the star-chamber against Mr. Lilburne was illegal, barbarous, bloody, and tyrannical, and that reparations ought to be given him for his imprisonment, sufferings, and losses sustained by that illegal sentence." Nevertheless, he tells us, that he never received any remuneration, though he had been put to the expence of from 1000 to 1500*l.*, and had endured seven or eight imprisonments for nothing. When an army was raised by parliament, Lilburne entered into it as a volunteer, and, at the battle of Edge-hill, he acted as a captain of infantry. He behaved with distinguished bravery at the battle of Brentford, where he was made prisoner, carried to Oxford, and arraigned on a charge of high-treason, but was saved by a declaration of parliament, threatening reprisals, and was soon after exchanged, was received with triumph by his party, and rewarded with 300*l.* as a compensation for his sufferings. Cromwell and Fairfax would willingly have employed him after they had new-modelled the army in 1645, and given him a high command; but his dislike to the Presbyterian church government would not permit him to serve the party then in power, and he laid down his sword to resume his pen, which he employed against Prynne, Lenthall, and other persons. He was in consequence committed to Newgate on a charge of seditious practices, but no bill being found against him, he was released without trial. He next was brought before the house of lords for certain reflections cast on the earl of Manchester, in a work entitled "The Just Man's Justification;" being examined upon interrogatories respecting the writing of that work, he not only refused to answer questions, but protested against their jurisdiction over him. He had stated the argument on this point, in full, in his "Legal and Fundamental Liberties of the People of England;" which he had maintained in the house, but which proved of no avail, as the house immediately made an order "that he be committed a close prisoner in Newgate, and that none have access to him but his keeper, until this court doth take farther order;" that is, said Lilburne, "when they turn honest and just, which I confidently believe will never be." So much was he now regarded by the people as a champion of liberty, that a remonstrance, signed by many thousand names, was presented to the house of commons in his behalf. This failing of effect, he continued to publish pamphlets, in which he displayed his grievances in such bold and virulent language, that he rendered the leading men of all parties his enemies. It should, however, be observed, that the leading men alluded to, were those who were either adherents to the king, or those who were attached to Cromwell; but Lilburne, perceiving that both parties were hostile to the liberties of the subject, did not scruple to oppose all their projects, which he suspected, and justly too, would lead to the establishment of a tyranny in some shape or other. He charged Cromwell with a design of usurping the sovereignty; and accused him and his relation Ireton of high treason, for which he was ordered to be tried as a libeller. At this period he had for many friends among the people, that the house of commons judged it proper to discharge him from prison, and make an order for remunerating him for his sufferings. At the time of the king's death, Lilburne was busy in plans for settling a new model of government. Finding the leaders of the army resolved to keep the power in their own hands, he opposed them with his usual intrepidity and maintained the right of the people to form a

constitution for themselves. So dangerous now did he appear to Cromwell and his council, that he was again committed to the Tower, and was brought to his trial for high treason before a special commission. On this occasion he defended himself with great firmness, never once shewing a disposition to crouch to his prosecutors or his judges: he felt that he stood on firm ground, and was determined not to bend to the circumstances of the times. The trial lasted many hours, and when the jury were about to retire to consider their verdict, the foreman asked permission of the court to take a cup of sack among them; to which the judge replied, it was impossible, they could have no manner of refreshment while impannelled in a case of high treason. One of the court was willing they should be indulged, but the chief justice said he dare not permit it. Mr. Lilburne's jury retired for three quarters of an hour, and then brought in a verdict of Not Guilty: which, says the reporter of the trial, was received with unanimous plaudits from within and without, that continued without intermission for more than half an hour. The judges, who seem to have strained hard for a verdict of guilty, were abashed and confounded. Lilburne stood silent, affected and oppressed with the gratulations of his countrymen, unable to express those sensations which he unquestionably felt for the general interest which was taken in his cause. A medal was struck of his head, with the following inscription: "John Lilburne, saved by the power of the Lord and the integrity of his jury, who are judges of law as well as of fact." The names of the jurymen were given on the reverse; names which must live so long as England is a free country. Mr. Hume, speaking on this subject, and of those who had usurped the government, and of their unwillingness to trust their cause to the decision of juries, chosen according to the ancient constitution of the country, says, "They had evidently seen in the trial of Lilburne what they could expect from juries. This man, the most turbulent, but the most upright and courageous of human kind, was tried for a transgression of the new statute of treasons; but though he was plainly guilty, he was acquitted to the great joy of the people. Never did any established power receive so strong a declaration of its usurpation and invalidity, and from no institution, besides the admirable one of juries, could be expected this magnanimous effort."

A new offence which he gave to parliament caused that body to pass a sentence of heavy fine and punishment against him, upon which he retired to Holland. Here he remained till the dissolution of the Long Parliament, when he used all his interest to obtain a passport for his return to England, and not succeeding, he ventured, in June 1653, to come back without one. He was very soon apprehended and committed to Newgate, and being brought once more to trial, he defended himself on the plea of illegality in his sentence of banishment, and was accordingly acquitted by his jury. The government, however, ordered him to be immediately sent out of the kingdom, but giving security for his future quiet behaviour, he was suffered to remain. The nature of the security here referred to has excited some doubts in the historian; but the writer of the article in the *Biographia Britannica*, makes it appear highly probable, that Lilburne's brother Robert became security in this instance for his future peaceable demeanour. Having brought together the arguments in favour of this hypothesis, the writer referred to says, "Laying then all these circumstances together, can there be any reasonable doubt who was the person that averted Cromwell's wrath against our author, and saved him from transportation, and after going through an uncommon variety of storms, tempests, and shipwrecks, settling the

whether.

weather-beaten vessel in a peaceful and still harbour; where, partly through a full conviction, that all possibility of success in any further strugglings against his adversary was cut off, and chiefly out of a religiously affectionate regard for his entirely beloved brother who stood responsible for him, he passed the remainder of his days in perfect tranquillity, equally undisturbed by, and undisturbing his triumphant competitor." John Lilburne now settled at Eltham, in Kent, joined the society of quakers, and even preached at their meetings in Woolwich, and other adjacent places, till his death in 1657, at the early age of thirty-nine. He had a wife, who possessed the same undaunted spirit with that of her husband, and was his faithful and affectionate helpmate in all his sufferings. By Anthony Wood, Lilburne is styled, "a great trouble-world in all the variety of government:" by other historians and biographers he has been represented to have been of so factious and quarrelsome a temper, that "if there were none living but him, John would be against Lilburne, and Lilburne against John." Such charges were brought against him by his contemporaries, and in his "Legal and Fundamental Liberties of the People of England," he has taken pains to rebut the calumnies of his adversaries, and to shew that his hand was never lifted up but against tyranny and tyrants: and at the close of that work he subscribes himself "An honest and true bred free Englishman, that never in his life feared a tyrant, nor loved an oppressor." If it were Lilburne's misfortune to be a trouble to the existing governments under which he lived; it must be remembered that he vindicated the cause of his country in opposition to the arbitrary measures of Charles I. and the usurpations of Oliver Cromwell; and however he might be regarded by his contemporaries, and misrepresented by party writers, posterity must look to him with respect, and should be thankful that such a man existed, in times of peculiar difficulty, when the will of the few had well nigh superseded the authority of the law, and when every thing holy and excellent in our constitution must have been for ever lost, but for the exertions of such patriots as Lilburne. His efforts in the public cause were not more zealous than they were pure and disinterested. What he conceived to be justice and the public good, he pursued against all parties with an invincible spirit, and through a life of persecution. He was, at the same time, a firm supporter of the laws of his country, which, in return, often supported him, and proved effectual barriers against arbitrary violence. Biog. Brit. Hume. Lilburne's Trial by Varax; and his Legal Fundamental Liberties of the People of England, revived, asserted, and vindicated.

LILEN, in *Geography*, a town of South America, in the province of Popayan: 15 miles S.W. of Cali.

LILESWARA, in *Hindoo Mythology*, a name of Siva, the regenerative power of the deity. (See SIVA.) It means Iswara (or the lord) who gives delight, and was assumed with manhood, in one of the numerous metamorphoses detailed in the Puranas, by this deity, who in this form became re-united to his spouse Parvati, giving delight to her in her terrestrial manifestation, under the name of Lileswari. (See PARVATI.) The Puranas abound in this description of incarnation of their male and female deities, which, thus veiled in allegory, are supposed to conceal historical and philosophical facts. (See PURANA.) Mr. Wilford, in several of the volumes of the Asiatic Researches, has pursued this allegorical maze with great industry. See more particularly vol. iii. vi. and viii. See also Hindu Pantheon, p. 389.

LILI, the name of one of the favourite remedies of Para-

celsus, the basis of which is antimony; but he has not given us the process for preparing it.

LILIA, in *Botany*, a natural order of plants, so called from *Lilium*, the Lily, which is one of them. Tournefort, who understood this order in a wider sense than more recent authors, denominated the plants which he referred to it, *lilacei*; Linnaeus, and most others, call them *liliaceae*.

The *lilia* constitute the fourteenth order in Jussieu's system, and the fourth of his third class. The essential characters of this class are "Cotyledon one. Stamens inserted into the calyx or corolla." He gives its distinctions at length as follows.

"Calyx of one leaf, tubular or deeply divided, superior or inferior, sometimes naked, more generally attended by a sheath containing one or many flowers, rarely by an involucre resembling an exterior calyx. Corolla none; for what is called corolla by Tournefort, Linnaeus, and others, in the opinion of the writer (Jussieu), is a real calyx. Stamens definite in number, rarely indefinite, inserted either into the lower or the upper part of the calyx, opposite to its segments: the filaments separate, rarely united; the anthers separate, of two cells. In a few instances the germen is feveral and superior; with as many styles and stigmas, and the same number of single-celled capsules, with one or many seeds, internally of two valves, which bear the seeds on their margins. In most cases the germen is single, superior or inferior; style single, rarely threefold, or wanting; stigma simple or divided; fruit pulpy or capsular, of three cells, with three seeds or many; sometimes two of the cells are abortive, or there is only one of the seeds perfected. The seeds of the berries are affixed to the internal angle of each cell; in the capsules, usually of three valves, they are inserted here and there upon the edges of an elevated receptacle, constituting the partition, in the middle of each valve, and separating along with it. The *coracium* is small, in a large horny albumen."

The order of *lilia* is thus defined.

Calyx inferior, coloured, in six deep segments, usually equal and regular. *Stamens* six, inserted into the bottom of each segment. *Germen* simple, superior; style one, rarely wanting; stigma in three divisions. *Capsule* superior, of three cells and three valves, with many seeds, which are ranged in a double row in each cell, and generally flat.

The *stem* is mostly herbaceous. Radical *leaves* sometimes sheathing; the rest sessile, for the most part alternate, rarely whorled. *Flowers* either naked, or furnished with a sheath, (*spatha*), or accompanied by a leaf resembling such; often drooping, the style being longer than the stamens.

The genera are eight; *Tulipa*, *Erythronium*, *Gloriosa*, (for which last Jussieu retains the name *Macdonaldia*), *Cyclaria*, *Fritillaria*, *Imperialis* (the Crown Imperial, separated from *Fritillaria*, because its nectariferous cells are round instead of oblong), *Lilium*, and *Fucox*.

Linnaeus calls his *lilia* the Patrician order, or Nobility of the vegetable kingdom, in his famous distribution of plants at the head of his *Systema Vegetabilium*. We may suppose that he had in view, in this instance, not only the analogies of the other orders, but especially the text, so often quoted, "consider the lilies of the field,—they toil not, neither do they spin." &c. in which these gorgeous plants seem more particularly indicated. The very species, which our Saviour had then perhaps before his eyes, is thought to have been the splendid *Amaryllis lutea*, with which the fields of Palestine are over-run at the end of autumn. Possibly this hint may be of use to biblical chronologists. The learned Olaus Cellius seems not to have adverted to this text, as alluding

to any particular plant. Some have, without any reason, taken for granted that the Garden Tulip was meant; but that plant is not a native of Palestine.

The order of liliaceous plants is now receiving most magnificent illustration at Paris, in a work expressly destined to that purpose, by M. Redouté, of which five volumes in folio have reached us. The figures are printed in colours, in the modern French manner. The descriptions are in French. Many plants, not properly belonging to the same family, are admitted into this publication, as a few of the *Orchideæ*, and *Scitamineæ*, which, though they interfere with its ostensible designation, certainly do not lessen its value, either as to beauty or utility.

LILIACEOUS PLANTS, in *Gardening*, all such as resemble those of the lily kind, in their flowers having six regular petals, in the form of a lily; or three, or even one petal deeply divided into six segments, assuming a lily-flower form: they have not, however, all flowers so large as that of the lily, some being considerably smaller; and as the common lily has no calyx, so several of the liliaceous flowers are also destitute of a cup; and others have cups, which are principally of that sort called a spathe. They may, therefore, be distinguished into such as have cups and such as have not.

Those with cups are all the different sorts of the common lily: the tulip, all the kinds; fritillary, and crown imperial; hyacinth; star of Bethlehem; bastard star of Bethlehem; tuberose; asphodel; squill; hemerocallis, or day-lily; anthericum, or spiderwort; aloe; yucca, or Adam's needle; gloriosa, or superb lily, &c.

Those with spathes or cups are the crocus; galanthus, or common snow-drop; leucocium, or great snow-drop; daffodil, narcissus, and jonquil; crinum, or asphodel lily; colchicum; iris, or flower-de-luce; hemanthus, or blood-flower; gladiolus, or sword-lily; Virginia spider-wort; amaryllis, including the Guernsey lily, belladonna lily, and Jacobea lily, &c.; paneraticum lily, &c.

It may be noticed, that the greater part of these liliaceous plants of both kinds are bulbous-rooted: some, however, have tuberous, and some fibrous roots; and all of them are perennial in root, but annual in the stalk or stem.

These are all ornamental garden-flowers, and most of them sufficiently hardy to grow in the open ground; though a few are proper for the green-house and stove, as they require protection. See these different genera.

LILIAGO, in *Botany*. See **ANTHERICUM**.

LILIASTRUM, the beautiful St. Bruno's lily. See **ANTHERICUM**.

LILIENDAL, in *Geography*, a town of Sweden, in the province of Nyland; 15 miles N.E. of Borga. N. lat. 60° 23' E. long. 26 3.

LILIENTHAL, a town of the duchy of Bremen, situated on the river Worp; 10 miles N.N.E. of Bremen.

LILIO-ASPHODELUS, in *Botany*. See **CRINUM** and **HEMEROCALLIS**.

LILIO-Fritillaria. See **FRTILLARIA**.

LILIO-Hyacinthus. See **SCILLA**.

LILIO-Narcissus. See **AMARYLLIS** and **PANCRATIUM**.

LILIUM appears to be a name of rather obscure origin; some deduce it from the Greek *λεῖον*, a lily, derived from *λεῖος*, smooth, not rough, also handsome, because the plant is conspicuous for the beauty of its flowers. It has moreover been called *λεῖον*, from *λεῖον*, dust, or pollen, because the flowers seem in general to be sprinkled with a powdery substance, from the abundance of their pollen. *Lilium* is adopted from Pliny and other Latin authors.

Linn. Gen. 163. Schreb. 218. Willd. Sp. Pl. v. 2. 64. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 240. Tournef. t. 195. Juss. 49. Lamarek. Illust. t. 246. Gærtn. t. 83.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronarie*, Linn. *Lilia*, Juss.

Gen. Ch. Cal. Perianth none. Cor. bell-shaped, narrower at the base; petals six, erect, lying over each other, obtusely carinated at their backs, more expanding and broader upwards; their tips obtuse, thick, reflexed. Nectary a longitudinal line, tubular, forming a channel in each petal from its base to the middle. Stam. Filaments fix, awl-shaped, erect, shorter than the corolla; anthers oblong, incumbent. Pist. Germen superior, oblong, cylindrical, marked with six furrows; style cylindrical, the length of the corolla; stigma thickish, triangular. Peric. Capsule oblong, six-furrowed, hollow, triangular, and obtuse at the top, of three cells and three valves; the valves connected by a network of fibres. Seeds numerous, incumbent in a double order, flat, outwardly semicircular.

Obs. The nectary, in some species, is bearded, in others naked. In some the petals are totally revolute, in others not so.

Eff. Ch. Corolla of six petals, bell-shaped, each petal marked with a longitudinal nectary. Capsule with valves connected by a network of fibres.

Examples of this beautiful and fragrant genus are the following. The colour of their flowers is either white, yellow, or red. The fourteenth edition of Linnæus's *Systema Vegetabilium* comprises ten species. Willdenow has sixteen, though his first, *L. cordifolium*, belongs to another genus, which Mr. Salisbury, in Tr. of Linn Soc. v. 6. 11, has proposed to call *Sauflurea*. (See **HEMEROCALLIS**.)

L. candidum. Common White Lily. Linn. Sp. Pl. 433. Sm. Prod. Fl. Græc. v. 1. 227. Curt. Mag. 278. Redouté Liliac. t. 199. Woodv. Med. Bot. t. 101. (*L. album*; Rudd. Elys. v. 2. 167.)—Leaves lanceolate, scattered, attenuated at the base. Corolla bell-shaped, smooth on the inside.—This is the *κλῆμα* of Dioscorides, and *κλῆμα* of the modern Greeks. Great doubts existed respecting the native habitat of this well known and elegant plant, till Mr. Hawkins, the friend and companion of Dr. Sibthorp, found it growing wild in that truly classical and celebrated spot, the vale of Tempe. It flowers early in the summer, and has been cultivated in our gardens from time immemorial. Root a large fleshy bulb, from which proceed many succulent fibres. Stem firm, upright, simple, usually rising to the height of about three feet. Leaves numerous, long, smooth, sessile. Flowers large, white, in a cluster at the top of the stem; the petals are of a beautiful shining white on their inside, ridged, and not quite so transparent or luminous on their outside.

Pliny and Ovid have each added their testimony to the general admiration in which this plant has been universally held. The former says, *Lilium Rosa nobilitate proximum est*. The latter has thus poetically ascribed its origin to the milk of Juno:

“Dum puer Alcides Divæ vagus ubera fuxit
Junonis, dulci pressa sapore fuit;
Ambrosiumque alto lac distillavit Olympo
In terras fumum Lilia pulchra dedit.”

Both these flowers have furnished ancient and modern poets with their share of metaphor; either singly

“—Vel mixta rubent ubi lilia multâ
Alba rosâ; tale virgo dabat ore calores.”

Æn. l. xii. 68.

The

LILIU M.

The flowers have a pleasant sweet smell, and were formerly used for medicinal purposes, particularly as an antiepileptic and anodyne. A water distilled from them was used as a cosmetic, and the "oleum liliorum" was supposed to possess anodyne and nerve powers: but the odorous matter of these flowers is very volatile, being totally dissipated in drying, and wholly carried off in evaporation by rectified spirit as well as water; and though both menstrua become impregnated with their agreeable odour by infusion or distillation, yet no essential oil could be obtained from several pounds of the flowers. Hence the Edinburgh College now directs the use only of the roots, which are mucilaginous, and are chiefly employed, boiled with milk or water, in emollient and suppurating cataplasms: it is not improbable, however, that the poultices formed of bread or farina, possess every beneficial quality ascribed to those of lily-root. Gerard recommends them internally in dropries. For this purpose, bread was made of barley meal, with the juice of the roots, and constantly used for a month or six weeks; but Dr. Lewis observes, that there are instances of similar cures by the use of common bread; and that probably, in one case as well as in the other, abstinence from liquids was the remedy. Lewis Mat. Med. Woodv. Med. Bot.

L. bulbiferum. Bulb-bearing, or Orange Lily. Linn. Sp. Pl. 433. Jacq. Austr. t. 226.—Leaves linear-lanceolate, scattered. Corolla bell-shaped, erect, glandular and rough on the inside, downy without.—A native of Italy, Austria, and North America. It flowers in June and July. *Bulb* composed of numerous thick, white, loosely imbricated scales. *Stem* upright, about a foot and half high, striated and angular, smooth, or slightly hairy. *Upper leaves* spreading horizontally, having a roundish pale-green or purplish bulb at their base. *Flowers* large and handsome, of a beautiful red or orange colour, paler on the outside, inodorous.

There are several varieties of this generally cultivated plant, of which the most common is that figured in Curt. Mag. t. 36, but the darker tinted one of Jacquin is handsomest, bearing more bulbs and fewer flowers.

L. superbum. Superb Martagon Lily. Linn. Sp. Pl. 434. Curt. Mag. t. 936. Redouté Liliac. t. 103.—Lower-leaves whorled, the rest scattered. Flowers forming a branched pyramid, reflexed. Corolla revolute. A native of North America, whence it was imported by Mr. Peter Collinson in the year 1738. It flowers from June to August. Wild specimens of this beautiful species are seldom found with above three or four flowers, but they may be brought, by careful cultivation, to bear from twelve to fifteen. *Bulb* white as ivory. *Stem* round, smooth and even, two or three feet in height, branched. *Flowers* large and handsome, one at the end of each branch, red or yellow with dark spots; their smell is disagreeable.

One of the finest figures that can be exhibited of this or any other plant, may be seen in the second number of Dr. Thornton's Illustration of the Linnæan System.

L. philadelphicum. Philadelphia n Lily. Linn. Sp. Pl. 435. Curt. Mag. t. 519. Redouté Liliac. t. 104.—Leaves whorled. Flowers erect. Corolla bell-shaped; petals unguiculate.—Sent from Philadelphia by Mr. John Bartram in the year 1757. It flowers in July. *Bulbs* small, white and scaly. *Stem* rather more than a foot high, bearing two elegant flowers at the summit. Petals red and yellow, spotted towards their base with darkish red or purple.

Among the most common species in the gardens are *L. chalcedonicum*, Curt. Mag. t. 30, which is the Scarlet Martagon so remarkable for its fine colour; and *L. Mar-*

tagon, Curt. Mag. t. 893, the Purple Martagon, or Turk's Cap Lily; both are very hardy—*L. tigrinum*, Curt. Mag. t. 1237, (*L. speciosum*; Andr. Bot. Reper. t. 586.) is however perhaps the most showy species of all. It was introduced from China, by Sir Joseph Banks, in the year 1807, and is found to bear our climate if cultivated in a border of bog earth, flowering in August.

LILIU M. Convallium. See CONVALLARIA.

LILIU M. in *Gardening*, containing plants of the bulbous-rooted flowery perennial kind, of which the species usually cultivated are the common white lily (*L. candidum*); the Cateby's lily (*L. Catebyi*); the bulb-bearing or orange lily (*L. bulbiferum*); the purple martagon lily, or Turk's cap (*L. martagon*); the pomponian lily (*L. pomponium*); the scarlet martagon lily (*L. chalcedonicum*); the great yellow martagon lily (*L. superbum*); the Canada martagon lily (*L. Canadense*); the Kamtschatka lily (*L. Kamtschatkense*); and the Philadelphian martagon lily (*L. Philadelphicum*).

In the first sort the principal varieties are, with striped flowers, or with blotched purple flowers, or with variegated striped leaves, or with yellow edged leaves, with double flowers, and with pendulous flowers. But the first of these varieties is now become common; the purple stain giving the flower a dull colour, the common white is generally preferred. The second is chiefly valued for its appearance in winter and spring; for the leaves coming out early in the autumn, spreading themselves flat on the ground, and being finely edged with a fine yellow band, make a pretty appearance during the winter and spring months, as it flowers earlier than the plain sort. The third is of little value, as the flowers never open well unless they are covered with glasses; nor have they any of the rich odour of the common sort. The fourth came originally from Constantinople; the stalk is much more slender; the leaves narrower, and fewer in number; the flowers not quite so large, and the petals more contracted at the base; they always hang downwards; the stalks are sometimes very broad and flat, appearing as if two or three were joined together: when this happens, they sustain from sixty to one hundred flowers, and sometimes more; this, however, is merely accidental, as the same root scarcely ever produces the same two years together, or in succession.

The third sort has varieties with double flowers, with variegated leaves, with smaller stems, and the bulb-bearing fiery lily, which seldom rises more than half the height of the others; the leaves are narrower; the flowers smaller, and of a brighter flame-colour, few in number, and more erect: they come out a month before those of the common sort, and the stalks put out bulbs at most of the axils, which, if taken off when the stalks decay, and planted out, they readily produce new plants.

In respect to the sub-varieties, they are the great broad-leaved, the many-flowered, the small, and the hoary bulb-bearing lily.

The fourth kind varies with white flowers, with double flowers, with red flowers and hairy stalks, and with imperial divided stalks.

The fifth species has varieties with double red flowers, with white flowers, with double white flowers, with red spotted flowers, with white spotted flowers, with yellow spotted flowers, with early scarlet flowers, and the major scarlet pompony.

And the sixth sort, according to Mr. Curtis, varies in the number of flowers, from one to six, and the colour in some is of a blood-red; also, with deep scarlet flowers, with purple flowers, and with large bunches of flowers.

Of the eighth species there is a variety with larger deeper-coloured flowers.

Method of Culture.—All these sorts are capable of being increased by planting the off-sets of the roots, and by sowing seeds to obtain new varieties.

And the roots of all the sorts afford plenty of off-sets annually, which, when greatly wanted, may be taken off every year in the autumnal season; but once in two or three years is better, according as they are wanted; the proper time for which is in summer and autumn, when the winter is past and the stalks decayed, either separating the off-sets from the mother-bulbs in the ground, or taking the whole up, and separating all the off-sets, small and great, from the main bulbs; the small off-sets being then planted in beds a foot asunder, and three inches deep, to remain a year or two, and the large bulbs set again in the borders, &c. singly. The off-sets in the nursery-beds may also, after having obtained size and strength for flowering in perfection, be planted out where they are wanted for ornament.

But the sowing of seed is chiefly practised for the martagons, to obtain new varieties, which should be done in autumn, soon after the seed is ripe, in pots or boxes of rich light sandy earth, with holes in the bottoms half an inch deep: placing the pots in a sunny sheltered situation all winter, refreshing them often at first with water, and the plants will appear in the spring: when about April, remove them to have only the morning sun all the summer, giving moderate waterings; in August, the bulbs should be transplanted into nursery-beds in flat drills, an inch deep, and three or four asunder; when, as the bulbs will be very small, scatter the earth and bulbs together into the drills, covering them with earth to the above depth: and after having grown in this situation till the August or September following, they should be transplanted into another bed, placing them eight or nine inches each way asunder, to remain to shew their first flowers; after which they may be finally planted out into the pleasure-ground.

And new varieties of the other sorts may be raised in the same way. Likewise, the bulb-bearing varieties may be increased by the little bulbs put forth from the axils of the leaves, without taking up the old bulbs, where it is necessary.

And the same method of planting and general culture answers for all the different sorts and varieties.

It may be noticed, that the most proper time for planting and transplanting them is in autumn, as has been seen, when their flowers and stalks decay, which is generally about September; the roots being then at rest for a short space of time, as well as for procuring roots to plant out. The bulbs taken up at the above season may be kept out of ground, if necessary, till October or November: the white lilies, however, do not succeed, if kept long out of the earth; and all the others succeed best, when planted again as soon as possible. The bulbs of all the sorts are sold at the nurseries.

They should be planted singly, as they soon increase by off-sets into large bunches, disposing them in a semblage in different parts of the borders, and towards the fronts of the principal shrubby clumps; placing them three or four inches deep, and at good distances from one another, intermixing the different sorts, placing some forward, and others more backward, to effect the greater show and variety. And some may likewise be planted in separate beds by themselves, twelve or fifteen inches asunder, either of different sorts together, or each in distinct beds, or in separate rows, &c.

When they have been thus planted out, few of the sorts

require any particular culture, as they are capable of enduring all weather at every season. It is, however, necessary to destroy all weeds; and, as some of them run up with pretty tall slender stalks, to support them with sticks, to preserve effectually their upright position, by which their flowers will appear to the best advantage.

But some of the more tender sorts, as the second, fourth, eighth, and tenth species, should be protected in severe winters, by applying tanner's bark, or some other similar substance over their roots. And they should all, as already stated, remain undisturbed two or three years, or longer; as by remaining, they flower stronger after the first year; and having increased by off-sets into large bunches, many stalks will rise from each bunch of roots, so as to exhibit a large cluster of flowers: it is, however, proper to take up the bulbs entirely every three or four years at least, at the decay of the stalk, to separate the increased off-sets, both for propagation and to disburthen the main roots, and give them room to take their proper growth in. As soon as they are taken up in the autumn, all the sorts should, as already observed, be replanted as soon as possible, especially the white lily sorts, as they soon begin to emit roots.

All the sorts and varieties are valuable, as plants of ornament, for the beauty of their flowers, which have a noble appearance: they are of course proper ornaments for the pleasure-ground; and when the different sorts are properly intermixed, they effect a most elegant variety, succeeding each other in blow upwards of three months. When wanted particularly for shady or close places, the common white lily, orange lily, and common martagons, are the most proper, as they thrive under trees. The orange lily also answers well in small gardens, in the midst of buildings in towns and cities. Besides planting the different sorts for the beauty of their flowers, many of the striped-leaved white lily sorts should be placed towards the fronts of the most conspicuous parts, for the beauty of their leaves in autumn, winter, and spring, which, if disposed alternately with the common white lily, whose leaves are entirely green, a most striking variety will be produced. But the tall-growing sorts are only proper for large borders and clumps, in mixture with other large kinds of the herbaceous plants.

LILIUM lapideum, a name given by the writers, in *Natural History*, to a fossil body found in some parts of Germany; which plainly shews, that it was once a species of star-fish; though the animal be not, at this time, known in its recent state. Klein, who has well considered this body, in compliance to the vulgarly received names of things, calls this the *entrochus ramosus*, or branched *entrochus*; and the resemblance some of its parts have to the common entrochi, shews plainly, that their origin has been the same, and that they are fragments either of this species or of the Magellanic star-fish. The recent fish not being found from which the *lilium lapideum* is formed is no peculiar fate, but is common to it, and to the cornua Ammonis, and many other animal remains.

LILLE, or **LISLE**, in *Geography*, a city of France, and principal place of a district, in the department of the North. Before the revolution, it was the capital of French Flanders. It is situated in a marshy but rich soil, surrounded with walls, and strongly fortified by marshal Vauban. The river Doule crosses it. It is said to contain 170 streets, 30 public places, 8000 houses, and, by the most recent statement, 54,756 inhabitants, on a territory of 77½ kilometres, in 14 communes. Before the revolution it had several religious houses. It was divided into seven parishes, and had seven gates, some of which were admired for the style of their architecture. Its manufactures are those of cloth, candlers,

bankers,

sankeens, stuffs of silk and woollen, cotton, linen of all qualities and designs, lace, ribbons, carpets, hats, stockings, paper, soap, &c. The citadel of Lille has been reckoned one of the best works of Vauban, and, except Turin, the strongest in Europe. N. lat. 50° 38'. E. long. 3° 7'.

LILLEBONNE, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Le Havre; 16 miles E. of Havre. The place contains 601, and the canton 8685 inhabitants, on a territory of 135 kilometres, in 20 communes.

LILLERS, a town of France, in the department of the Straits of Calais, and chief place of a canton, in the district of Bethune; 6 miles W.N.W. of Bethune. The place contains 4107, and the canton 14,682 inhabitants, on a territory of 105 kilometres, in 9 communes.

LILLO, GEORGE, in *Biography*, an English writer of tragedies, born in London in the year 1693, was the son of a Dutch jeweller, by an English mother. He was brought up to his father's trade, and carried on the business with great reputation for several years. His first publication, as a literary character, was entitled "Sylvia, a ballad-opera;" but his fame is founded on his tragedies, which are representations of domestic distress in common life, exhibited for a moral purpose. By the choice and management of his stories, he succeeded in rendering them eminently pathetic, and he displayed no inconsiderable knowledge of the human heart. His tragedies are "George Barnwell," "Fatal Curiosity," and "Arden of Feversham." The first of these is, we believe, uniformly brought on the stage about Christmas in every year, and it generally brings crowded houses: the play entitled "Fatal Curiosity" is mentioned by the late James Harris, esq. in his "Philological Inquiries," as a fine example of the gradual unfolding of a scene of horror, not less perfect than that which has been so long and highly applauded in the *Œdipus* of Sophocles. Attempts have been made to revive its reputation, but without success. The "Arden of Feversham" was a posthumous piece. His other performances have long since been forgotten. He died in 1739, at the age of 47, and his works were collected and edited in 2 vols. 8vo. by Mr. Davies, with a short account of his life; to which the reader is referred for farther particulars. See also the new edition of the *Biographia Dramatica*.

LILLO, in *Geography*, a town of Spain, in New Castile; 28 miles E.S.E. of Toledo.

LILLO, a fortress of Brabant, on the E. side of the Scheidt, built by the Dutch in 1584, and ever since garrisoned. This fortress, which guards the passage to Antwerp by large vessels, was taken by the French in 1794; 9 miles N.W. of Antwerp.

LILLO, in *Ichthyology*, a name given by the Rhodians to the labrus.

LILLY, JOHN, in *Biography*, an English writer, was born about the year 1553, and educated at Magdalen college, from whence he removed to Cambridge, after he had taken his degrees in arts. On his arrival in London, he became acquainted with some of queen Elizabeth's courtiers, by whom he was caressed as a poet and a wit; and her majesty, on particular festivals, honoured his dramatic pieces with her presence. He attended the court several years, yet so little did he get by his attendance there, notwithstanding his literary reputation, that he was under the necessity of petitioning the queen for a small stipend to support him in his old age. He died about the year 1600. He was author of several plays, as *Endimion*; *Campaspe*; *Alidas*; acted before queen Elizabeth; the *Maid's Metamorphosis*, &c.

VOL. XXI.

LILLY, WILLIAM, an English astrologer, was born at Didsbury, in Leicestershire, in the year 1602, and was educated at Ashby-de-la-Zouch. The knowledge he acquired at this place was very scanty, owing to the short time that he was allowed to remain in it. In 1620 he came to London to seek his fortune, and was bound apprentice to a tradesman in St. Clement Danes. In 1624 he became book-keeper to the mauler of the Salters' company, on whose death he married his widow. Being now his own master, and possessed of some fortune, he spent much time in frequenting sermons, lectures, &c. and became attached to the Puritan party. In 1632 he studied astrology under a person named Evans, a profligate clergyman, who, on account of certain immoralities, was obliged to quit a curacy. Lilly in a few weeks obtained of his master all the requisite knowledge of his art, and in a short time excelled him in calculation. The first specimen which he gave the public of his skill in astrology, was an intimation, that the king had chosen an unlucky horoscope for his coronation in Scotland. About the year 1634 he got possession of a book in MS. entitled "Ars notoria," teaching the pretended occult sciences, from which he eagerly imbibed the doctrine of the magic circle, and the invocation of spirits, which he practised for some time, using certain prayers prescribed in it, addressed to angels whom it represents to be instructors of men in these grand *arcana*. Previously to this, few persons, who practised in the astrological art, pretended to go farther than to endeavour to trace out and recover stolen goods; but Lilly treated this part of the mystery with great contempt, and laid claim to the supernatural sight, and the gift of predicting future events, which he well knew how to turn to his own advantage. In 1636 he settled at Hertham, near Walton on Thames, in Surrey, where he remained till 1641, when he came to London, with a number of curious books, in his own art, which he had purchased in the country. In 1644, he published his "Merlinus Anglicus," an almanac, which he continued annually till his death, and several other works which were written on the subjects of his art; devoting his pen and other labours sometimes to the king's party, and sometimes to that of the parliament; raising his fortune by favourable predictions to both parties, at one time by presents, and at another by pensions. Lilly was certainly consulted respecting the king's projected escape from Carisbrook-castle, and by his advice and contrivance the monarch attempted several times to make his escape from his confinement: he procured and sent aquafortis and files to cut the iron bars of his prison windows, but advising and writing for the other party at the same time. In 1648 and 1649, he read public lectures on astrology, for the improvement, as he pretended, of young students in the art, and managed matters so well, and profitably, that in 1651 and 1652, he laid out nearly 2000*l.* in an estate at Hertham. During the siege of Colchester, he and Booker, another astrologer, who was also a licenser of mathematical books, were sent thither to encourage the soldiers, which they did, by assuring them that the town would soon be taken, which proved true in the event. In the year 1650, having predicted in his almanac that the parliamentary government would be overturned, he was summoned to answer for his conduct, but during the interval of four-and-twenty hours, which were allowed him, he got the obnoxious leaves reprinted, and carried before the committee six copies thus altered, which he said were copies of his edition, the others having been printed with a view to ruin his reputation. By this trick and falsehood he escaped with only an imprisonment of thirteen days. In 1655, he was indicted for giving an opinion in the case of

stolen goods, but the evidence being insufficient to convict him he was acquitted. In 1659, he received a handsome gold chain and medal from the king of Sweden, on account of his having mentioned that monarch in his almanac for two successive years with applause. On the restoration of Charles II. he was examined as to the person who decapitated the late king, and declared that it was cornet Joyce. On account of the part which it was known he had taken during the commonwealth, he was glad to sue out a pardon under the great seal, which was granted him. In 1665, when the plague raged in London, he removed to Herisham. After the great fire of London in 1666, he was examined as to the perpetrators of the deed, but he was unable by his art to satisfy his employers. Shortly after this he adopted for a son a person named Henry Coley, a tailor by trade, and gave him the profits of his almanac. Lilly died at Herisham in 1681, when he was about seventy-nine years of age. His works were numerous, the titles of which are given in the Biog. Brit., and also in Hutton's Mathematical Dictionary: the chief of them are "Christian Astrology;" "A Collection of Nativities;" "Observations on the Life and Death of Charles late King of England;" and "Annus Tenebrosus, or the Black Year."

LILLY of Paracelsus. See TINCTURE of Metals.

LILLY Point, in *Geography*, a place of America, in King William County, Virginia, in which is a post-office; 134 miles from Washington.

LILLOAN, a town on the E. coast of the island of Sibu; N. lat. 10 40'. E. long. 123 45'.

LILY, WILLIAM, in *Biography*, a famous schoolmaster and grammarian, was born at Odham, in Hampshire, about the year 1446. He was educated at Magdalen college, Oxford, where he took a degree, and then went on a pilgrimage to the Holy Land. On his return he pursued his studies at Rhodes, which island, after the capture of Constantinople, was the residence of several learned men, under the protection of the knights, its possessors. Here he studied, and made great progress in, the Greek language; but for farther improvement in it, and in the Latin tongue, he visited Rome, and attended the lectures of the most celebrated professors. He now returned to London, and opened a school for the learned languages, rhetoric, and poetry, which he taught on pure classical principles. In 1510, when dean Collet founded St. Paul's school, he appointed Lily the first master, a station which he occupied with singular utility for twelve years. He died of the plague in 1522, or 1523. Lily was much esteemed by his contemporaries, as well for his moral character, as for his literary abilities. He was the author of several Latin poems and tracts, but is best known for the grammar that goes under his name, and is still used in our public schools. This was not wholly of his own composition, having been assisted in it by the labours of cardinal Wolfey and dean Collet. Biog. Brit.

LILY, GEORGE, eldest son of the preceding, was born in London, and educated at Magdalen college, Oxford, after which he was made canon of St. Paul's and prebendary of Canterbury. He was the first person who published an exact map of Britain: he died in 1559, and left behind several works of merit, as "Anglorum Regum Chronices Epitome;" "Regum Anglie Genealogia;" "Catalogus five Series Pontificum et Cesarum Romanorum," &c. He left likewise a MS. life of bishop Fisher, which is deposited in the library of the Royal Society. Biog. Brit.

LILY, in *Botany*. See LILIEUM.

LILY, in *Coronula*, the common name of this well known flower plant. See AMARYLLIS and LILIEUM.

LILY, *The yellow water*. See MENYANTHUS.

LILYBETHUM, now *Marfala*, in *Ancient Geography*, a town of Sicily, S. of Drepanum, and near the promontory of the same name, now called Cape Becco. It was the principal fortress of the Carthaginians in Sicily, and the only city that resisted Pyrrhus when he passed into this island in the 475th year of Rome; but having been ineffectually besieged for five years, it was ceded to the Romans after the victory of Lutatius, A. U. C. 511. The ill. *Agades*, the modern Maretimo, which is opposite to Marfala, seems to be the key of that immense harbour. It is formed by rocks, little low islands, tongues of land, and sand-banks, which break the waves on all sides, and form a large semi-circle, within which the sea is always calm. It was from this fort that the formidable fleet commanded by Scipio Africanus sailed, when he set out for Africa in the second Punic war, A. U. C. 548. The beauty of this harbour induced the Saracens to call it "Marfala," signifying, in their language, the "Port of God." The number of inhabitants at Marfala is estimated at 25,000. Of this famous port and impregnable city, the traces that remain are some few ruins of the ancient walls W. of the town, built with enormous masses of stone, which no machine, before the invention of cannon, could shake. In front of these walls were deep ditches, hewn out of the rock, some parts of which still exist. Here is no longer any anchorage for shipping, and the port is only fit for the reception of small barks. It was destroyed, as it is said, by Don John of Austria, who being unable to defend it, would not leave it open to the Africans, who were only at the distance of 50 leagues. At present Marfala has only a small road, to which vessels resort in order to load with tunny, and the ashes of kali, which are made here in great abundance, and form the principal and almost sole object of the commerce of the country. The merchants of Marseilles come hither to purchase it for their soap manufactories.

LIMA, in *Geography*, an audience of Peru, erected in the year 1542, which contains within its jurisdiction one archbishopric and four bishoprics; viz. those of Truxillo, Guamanga, Cuzco, and Arequipa. The archbishopric of Lima comprehends 15 jurisdictions, viz. the circuit of Lima, Chancay, Santa, Canta, Canete, Ica, Pisco, and Nasca, which three places form one jurisdiction, Cuzacama, Guanoeco, Yauyos, Caxatambo, Sarma, Joux, Conchucos, Guaylas, and Guamalies. The diocese of Truxillo contains seven jurisdictions; that of Guamanga nine; that of Cuzco fourteen; and that of Arequipa six.

LIMA, a famous city of the audience of Lima, and capital of the vice-royalty of Peru. This city, called "Ciudad de los Reyes," or the city of the kings, from its having been founded by Don Francisco Pizarro, on the feast of the Epiphany, A. D. 1535, is situated in the spacious and delightful valley of Rimac, whence, by corruption, the name Lima is derived: Rimac being the appellation of an idol to which the native Indians used to offer sacrifices, as the

Vacas

Yncas also did, after they had extended their empire hither: and as it was supposed to return an answer to the prayers addressed to it, they called it, by way of distinction, Rimac, or he who speaks. The situation of this city is peculiarly advantageous, as it is placed in the centre of a valley, the whole of which it commands. Towards the north, at a considerable distance, is the Cordillera, or chain of the Andes; whence some hills project into the valley, the nearest of which, to the city, are those of St. Christopher, and Amancaes. A river of the same name washes the walls of Lima, over which is an elegant and spacious stone bridge, with a gate of beautiful architecture, that forms the entrance into the city, and leads to the grand square, which is large, and finely ornamented. In the middle of it is a noble fountain of bronze, and such objects, useful as well as ornamental, are not uncommon. The form of the city is triangular, the base, or longest side, extending along the banks of the river. Its length is 1920 toises, or $\frac{2}{3}$ ds of a league; and its greatest breadth from N. to S., that is, from the bridge to the angle opposite to the base, is 1080 toises, or $\frac{1}{3}$ th of a league. It is surrounded with a brick wall, flanked with 34 bastions; and in its whole circumference it has seven gates and three posterns. On the side of the river opposite to the city is a suburb, called St. Lazaro, which has lately increased; all its streets, like those of the city, are broad, parallel, and at right angles, forming squares of houses; all well-paved, supplied from the river with streams of water, arched over, so that they contribute to cleanliness and salubrity, without the least inconvenience. The number of streets is said to be 355, and of houses 3941. Towards the E. and W. parts of the city, within the walls, are many fruit and kitchen-gardens; and most of the principal houses have gardens for amusement, which are continually refreshed with water by means of canals. The whole city is divided into five parishes, and abounds with churches, convents, nunneries, colleges, and charitable foundations, which it would be tedious to recount, and it has also a famous university, founded in 1576. All the churches and chapels are large, and adorned with paintings and other decorations of great value. The viceroys of Peru usually reside at Lima, enjoying all the privileges of royalty, and, besides assisting at the courts of justice, and the councils relating both to the finances and war, give every day public audience to all sorts of persons; for which purpose, there are in the palace three very grand and spacious rooms. Under the viceroy there is a number of officers, and of tribunals for the transactions of the business of the city and audience. The Cabildo, or Ayuntamiento, that is, the municipal body of the city, enjoys particular privileges; and the revenue of the capital exceeds 36,000 dollars. Since 1786, there is also a judge of the police, assisted by an able architect, and other officers.

Upon the whole, we may observe, without reciting particulars, that Lima is not only large, magnificent, and distinguished as the capital of the kingdom, by the residence of the viceroy, and the superior courts and offices, but that it has an acknowledged superiority over the other cities in that part of the world, from the institutions that are established for the advancement of literature and the sciences. It is a place where luxury prevails to a great degree; the malls are crowded with handsome carriages; the number of coaches and calashes being computed at 1400. Nevertheless, amusements are rare, and literature is neglected. Little encouragement is given to publications of a kind most likely to interest the inhabitants of the city and its environs. The university of St. Mark is conducted on the plan of the Spanish universities. The theatre is a neat

building; but the exhibitions do not display much taste. Coffee-houses only began to be opened in 1771. Cock-fighting is a favourite amusement on Sundays and festivals; nor are bull-fights unknown.

The number of inhabitants in this city, according to the latest enumeration, amounts to 52,627; the monks and clergy being 1392; the nuns 1585; the Spaniards, in general, 17,215; with 3216 Indians, and 8560 negroes, the rest being Mestizos, and persons of other casts. The rich ecclesiastics, proprietors of entailed estates, military and civil officers, and physicians, advocates, attorneys, and artisans, may amount to 10,000; the rest being slaves or domestics. The want of occupation leads many of the females to vice; and the men are rather inclined to indolence and sloth. The population has declined since the erection of the new vice-royalty of La Plata; and it is likely still farther to decrease, notwithstanding an influx of 1400 persons of all sexes and conditions, who annually arrive as a supply; not to mention the Spanish girls, who, from the province of Piura in the north, and sea in the south, come hither to dispose of their charms either in marriage or love, those provinces being celebrated for female beauty. All the inhabitants of Lima, from the highest to the lowest, are fond of fine clothes, and they indulge their passion to great excess. The women's dress consists of a pair of shoes, a chemise, a petticoat of dimity, an open petticoat, and a jacket, which, in summer, is of linen, and in winter of fluff, to which some add a manticlette. Women of the lowest condition, whose whole stock of apparel consists merely of two chemises and a petticoat, wear bracelets, rosaries, and small gold images, about their necks and arms, to the value of fifty or sixty crowns. The females are, in general, of a middling stature, handsome, genteel, of a very fair complexion, with beautiful hair, and enchanting lustre, and dignity in their eyes. They are naturally gay, sprightly, jocular, without levity, and remarkably fond of music. The temperature of the air at Lima is agreeable; and though the difference of the four seasons is perceptible, they are all moderate, and none of them troublesome. Spring begins towards the close of the year, *i. e.* towards the end of November, or beginning of December; this is succeeded by summer, the heat of which is moderated by the south winds; at the latter end of June, or beginning of July, the winter begins, and continues till November or December, the autumn intervening. As rain is seldom or never seen at Lima, the place is equally free from tempests, and the inhabitants are totally strangers to thunder and lightning; there are, however, other inconveniences and evils to which they are obnoxious. In summer they are tormented with fleas, bugs, and mosquitoes; but the most dreadful calamity to which this country is subject is the recurrence of earthquakes, of which they have had several, which have almost ruined the city. These have occurred in 1582, 1586, 1609, 1630, 1655, 1673, 1687, 1690, 1697, 1699, 1716, 1725, 1732, 1734, 1745, and 1746; the latter being the most tremendous and destructive. As the best security against earthquakes, they build their houses mostly of wood, and the walls of wattleed osiers or canes, covered with clay, and painted. The distempers most common at Lima are malignant, intermittent, and catarrhus fevers, pleuritis, and coarctation; and these rage continually in the city. The small-pox is also known here; and when it occurs proves fatal to many. The wealth of this city is chiefly derived from the mines in the provinces to the north and south; but agriculture produces very much in the vicinity, and the fields supply food for a multitude of horses and cattle. The fertility of the soil was very early improved in ancient times by the care of the Yncas to cult

and arrange trenches in such a manner, as to conduct the water of the rivers to irrigate the soil; and when the Spaniards took possession of the country, they pursued the same plan; thus they watered the spacious fields of wheat and barley, large meadows, plantations of sugar canes, and olive trees, vineyards, and gardens of all kinds, which were rendered very productive. By the earthquake in 1687, the soil was so vitiated, that it became unfit for yielding wheat and barley; but after remaining 40 years in this state of sterility, it again so far recovered itself as in a considerable degree to become fit for grain as before. However, repeated earthquakes have been unfavourable. The fields in the neighbourhood of Lima are chiefly sown with clover, of which there is a very great consumption, as it is the common fodder for all beasts, particularly mules and horses, of which there is an inconceivable number. The bread at Lima is the best in all this part of America, both with regard to its colour and taste. The mutton and beef are also very good; and here is also plenty of poultry, pork, and fish; which latter article is supplied by the Indians of the coast, from the bay of Callao, and the villages of Cherillo and Lurín. The river of Lima, and the coasts, furnish anchovies and various sorts of shell-fish. The wines at Lima are of different sorts, white, red, and dark-red, and of each sort some are peculiarly excellent. They are imported from the coasts of Nasca, Pisco, Lucumba, and Chili, but the latter produces the best. That from Pisco has the greatest sale, and from the same place all the brandies used at Lima or exported are brought. Many of the dried fruits are brought from Chili, and by the trade carried on between the two kingdoms, Lima is supplied with all sorts of fruits known in Spain. At Lima there are no fabrics nor manufactures of any kind. Lima owes much of its magnificence and splendour to its being the capital of Peru, and the general staple of the kingdom. As it is the residence of the government and chief tribunals, it is also the common factory for commerce of every kind, and the centre of the products and manufactures of the other provinces, together with those of Europe, brought over in the galleons or register ships; and distributed from hence through the wide extent of these kingdoms. At the head of the commerce is the tribunal del Consulado, which appoint commissaries to reside in the other cities of its dependencies, extending through all Peru. The chief commerce of Lima is with Valparaiso, Concepcion, and Coquimbo, in the kingdom of Chili; the isle of Chiloe, and Arica, Ilo, and Pisco in the south; towards the north with Truxillo, Pacasmayo, and Payta, in the viceroyalty of Peru; with Guayaquil and Panama in the viceroyalty of New Granada; and with Realejo in Guatemala, and Acapulco, in Mexico. This trade is conducted by 10 ships, 14 merchant-frigates, 19 packet-boats, and a balandra, or small transport-boat; amounting in all to 354,500 quintals of tonnage, navigated by 460 seamen. After the destruction of the sea-port town of Callao by an earthquake in 1747 (see CALLAO), a new town or village was founded, at the distance of a quarter of a league, called "Ballavida." There is a fortress called "San Fernando," with a sufficient garrison to defend the bay, which in the S.W. is fenced by a barren island called "San Lorenzo." Here all the ships anchor about two leagues from Lima. The coasts of Nasca and Pisco send to Lima wine, brandy, raisins, olives, and oil; and the kingdom of Chili, wheat, flour, hard, leather, cordage, wines, dried fruits, and some gold. Every Monday, during the whole year, there is a fair at Callao, whither the traders or proprietors of commodities resort from all parts; and the goods are carried, according to the directions of the buyers,

on droves of mules kept for this purpose by the masters of the warehouses. Copper and tin in bars are brought from Coquimbo; from the mountains de Caxamarca and Chacapoyas, canvas made of cotton for sails and other stuffs of that kind, and Cordovan leather and soap are made all over Valles, the valley in which Lima is situated. From the southern provinces, as Plata, Oruro, Potosi, and Cuzco, is sent Vienna wool, for making hats and some stuffs of a peculiar firmness. From Paraguay, the herb called by that name is sent, of which there is a great consumption. The produce of the sales in the inland parts of the kingdom is sent to Lima in bars of silver, and piguas, which are porous and light masses of silver, being an amalgam of mercury and dust taken out of the mines. The silver is coined at the mint in this city. Lima has also its particular trade with the kingdoms both of North and South America. The most considerable commodity received from the former is snuff, which is brought from the Havannah to Mexico, and after having been there improved is forwarded to Lima, and conveyed from thence to the other provinces. There is no province in Peru, that does not transmit to Lima its products and manufactures; and supply itself from hence with the necessary commodities.

Lima also receives from the ports of New Spain, naphtha, tar, iron, and some indigo for dyeing. The kingdom of Terra Firma sends to Lima, leaf-tobacco and pearls, which find here a good market, as no mulatto woman is without some ornament made of them. The ladies and women of all ranks have an ancient custom of carrying in their mouths a "limpion," or cleanser, of tobacco. The intention of these is, as their name imports, to keep the teeth clean. The limpions are small rolls of tobacco, four inches long and nine lines in diameter, tied with a thread which they untwist as the limpion wastes. One end of this they put into the mouth, and after chewing it for some time, rub the teeth with it, thus keeping them always clean and white. All the timber used in building houses, refitting ships, or constructing small barks at Callao, is brought from Guayaquil, together with the cacao. S. lat. 12° 2' 31". E. long. 282° 27'. See Juan and De Ulloa's Voyage to South America, and Edalla, cited by Pinkerton's Geography. For further particulars, see PERU.

LIMA, a river of Spain, which rises in the province of Galicia, traverses the province of Entre Duero e Minho, and runs into the Atlantic, two miles below Viana. N. lat. 41° 40'. W. long. 8° 30'.—Also, a town of Arabia, in the province of Oman, near the coast; 32 miles S.E. of Julfa.

LIMACHU, a river of Chili, which runs into the Pacific ocean, S. lat. 30° 25'.

LIMACIA, in *Betany*, so named by Loureiro, from *Enax*, a snail, in allusion to the spiral furrows on its nut.—Loureir. Cochinch. 620.—Class and order, *Diacin Hexandria*. Nat. Ord. *Sarmentaceæ*, Linn. *Affragi*, Juss.

Gen. Ch. Male-flowers nearly terminal, crowded together. *Cal.* Perianth inferior, short, of six acute leaves, the alternate ones smaller, arranged altogether horizontally in a triangle. *Cor.* Petals three, triangular, almost erect, longer than the calyx; nectary equal to the calyx, divided into six, roundish, concave, fleshy segments. *Stam.* Filaments six, very short, each placed upon a segment of the nectary, and altogether forming a triangle; anthers of two cells, roundish.—Female flowers axillary, in pairs, on a separate plant. *Cal.* as in the male. *Cor.* Petals six, roundish, curved, unequal; nectary equal to the calyx, divided into six, turbinate, connivent segments. *Pist.* Germen superior, somewhat triangular; style none; stigmas three,

three, many-cleft, spreading. *Peric.* Drupa fleshy, rather kidney-shaped, containing a single seed. *Nut* spirally furrowed like a screw, the kernel simple.

Eff. Ch. Male, Calyx of six leaves. Corolla of three petals.—Female, Calyx of six leaves. Corolla of six petals. Stigmas three. Drupa kidney-shaped, spiral.

1. *L. scandens*. Cay Mè gâ of the Cochinchinese, and found in the woods of Cochinchina.—*Stem* shrubby, climbing, without tendrils, long, much branched. *Leaves* alternate, ovate-oblong, acuminate, entire, smooth. *Flowers*, both male and female, yellowish-green. *Drupa* small, smooth, acid and esculent.

LIMADASI, in *Geography*, a town of Kurdistan, on an island in the lake Van.

LIMANDA, in *Ichthyology*, a name by which some authors have called the flat-fish, which we in English call the *dab*, the *passer asper* of authors.

LIMARIA, a name given by Gaza and such other writers to the thynus or tunny-fish, called the *Spanish mackerel*.

LIMASOVA, in *Geography*, one of the smaller Philippine islands, near Leyta. N. lat. 10 1'. E. long. 125 2'.

LIMASSOL. See LIMESOL.

LIMATAMBA, a town of Peru, in the diocese of Cuzco; 25 miles W. of Cuzco.

LIMATURA *Martis Preparatoria*. See IROX.

LIMAX, in *Natural History*, the slug or snail, a genus of the Vermes Mollusca, class and order, of which the character is;—Body oblong, creeping, with a fleshy kind of shield above, and a longitudinal flat disk beneath; aperture placed on the right side, within the shield; feelers four, situated above the mouth, with an eye at the tip of each of the larger ones.

This genus, of which there are fifteen species mentioned in the *Systema Naturæ*, comprehends those animals that are commonly known by the name of slugs, or naked snails, which commit such depredations in our fields and gardens, especially in wet weather. Of the fifteen species six are common in our own country.

Species.

LEVIS. Body black, and almost without wrinkles. It is found among moss late in the autumn, and is about half an inch long. The body is glossy, with undulate transverse striae on the shield; narrower, and not so much wrinkled as the *ater*, which is the next mentioned.

ATER, or black slug; body black and furrowed with deep wrinkles. Of this species five varieties are enumerated: 1. The colour of this is deep black and pale beneath. 2. Black, with a pale greenish ridge down the back. 3. Black, beneath white; mouth yellowish. 4. Chestnut-brown, beneath white; mouth yellowish. 5. Dusky-brown, with a yellowish mouth and streak each side. This last is common in woods, meadows, fields, and gardens; and is from an inch and a half to five inches in length; it crawls very slowly, and leaves a slime upon whatever it passes over; feelers 14-ways black; the back is convex; the shield rough, with numerous dors; abdomen wrinkled.

ALBUS. This species, which is characterized by the whiteness of its body, contains four varieties. 1. The entirely white. 2. White edged with yellow. 3. White, with an orange margin and head. 4. White, with black feelers; it inhabits woods and groves, and is from a quarter to half an inch in length.

RUFUS. Body, above pale rufous, beneath white; it inhabits shady damp places, and the bottom of hills, is

about an inch and a half long; the body has neither spots nor belts; its feelers are larger than those of the *ater*.

FLAVUS. Body amber-colour spotted with white, and is found in herbage.

MAXIMUS. Body cinereous, with or without spots, there are six varieties, viz. 1. Body immaculate; shield black-blue. 2. Shield spotted with black; body with black longitudinal stripes. 3. Shield and body spotted with black. 4. Body with five whitish streaks, the lower one interrupted. 5. Body with white and cinereous wrinkles, and black spots in a double row. 6. Body edged with white; inhabits woods, gardens, and damp cellars; is from four to five inches long.

HYALINUS, takes its name from the colour of its body, which has a hyaline or glassy appearance; feelers obsolete; with a brown line reaching from the feelers to the shield; this is found in damp mossy places, and is very destructive to the young shoots of kidney-beans; belly with numerous interrupted wrinkles.

AGRESTIS. Rustic slug; body whitish, with black feelers; this species is divided into four varieties, of which the 1, is entirely whitish, immaculate; 2, whitish, with a yellowish shield; 3, whitish, with a black head; 4, whitish, with a cinereous back; 5, whitish, with scattered black specks.

The most curious of the above varieties is the second, that with a yellowish shield, or that which is characterized by Müller, in his *Hill Verm.* "*Limax albidus clypeo flavescente*," or by Gmelin, "*Limax albus, clypeo flavescente*;" it has been figured by Lillier, but more accurately, and with great care, in the fourth volume of the *Linnean Transactions*, in which it is exhibited in a state of repose, as it is seen in its progressive motion on the ground; and also as it is observed suspended from the branch of a tree, &c. both with respect to its upper and under surfaces. This variety is denominated in our own language the *springing slug*, and is commonly about three quarters of an inch long; it inhabits woods and other shady places. It was particularly noticed by Mr. Høy, and described in the first volume of the *Transactions of the Linnean Society*; at first he saw it suspended from the branch of a fir tree, and was not aware that it was a living creature. It was hanging by a single line or thread attached to its tail. This thread was in the upper part extremely fine, but near the animal it became thicker and broader, till at length it exactly corresponded with the tail. Its descent was at the rate of an inch in three minutes, a motion sufficiently slow for the minutest observations. The line by which it descended was drawn from the slimy exudation gradually secreted from the pores that covered its whole body. Apparently there was much exertion required to produce a sufficient supply of the liquid, and to force it towards the tail: it alternately drew back its head, and turned it as far as possible, first to one side, and then to the other, as if to press its sides, and thus promote secretion.

In addition to Mr. Høy's account, we shall give some farther particulars, taken from a curious paper by Dr. John Latham, in the fourth volume of the *Linnean Transactions*; a work that contains abundance of interesting matter, but which is too expensive to have a very general circulation beyond the members of the society. Speaking of the curious property belonging to the springing slug, the doctor says, "that it is a custom not unusual for this species of *limax* to pass from an height securely to the ground, by means of a thread of its own contraction seems manifest; for, on my friend's (Colonel Montague, F.L.S.) putting one of them on the projecting frame of a window, it immediately crawled forward."

forwards till it came to the projecting angle, from whence, without attempting to fix itself by its fore parts to any thing, it became visibly suspended by a thread from its tail. When it had descended two feet, the colonel took it up by the thread, and carried it to a distant room; but trying to fix it afresh, in order more accurately to observe its progress, the thread broke. He then put it on a frame about four feet from the ground; in a few minutes it was again suspended, and observing by his watch, it descended at the rate of three inches and a half in a minute." After repeated trials, the colonel, by means of glasses, was enabled to ascertain that the secretion, of which the thread was formed, was wholly from the under parts, and not from the back and sides, both of which appeared nearly dry, nor did it proceed from any orifice in the tail. This creature seems quite sensible of its abilities, for it extended itself from the bottom of the frame, with its head downwards, till the tail became suspended; and it was by means of an undulating motion of the belly that the flow of the viscous secretion was produced towards the tail, but in doing this the belly was contracted, being furnished with numerous transverse *rugæ*: at the same time the body and tentacula were fully extended, indicating no alarm whatever; the head was occasionally moved from side to side, which gave several turns to the right or left, as the centre of gravity lay; but as it was frequently turned one way as the other, the thread was not in the least twitted. The thread, on first leaving the tail, was five times as broad as it was at the eighth of an inch distant therefrom, but afterwards seemed of an equal size, and considerably smaller than the finest human hair. When a portion of this thread was placed under a microscope, it appeared contracted; it was pellucid and elastic. By another writer on this subject we are told, that by the application of the microscope, the slimy humour will be seen to come out insensibly from the glandular pores of the skin, like clear and minute points; these, by continuing a gentle pressure on the skin, will become small drops, and in the end form a considerable collection of matter. It may be also observed, that colonel Montague found several individuals of this variety that he could not induce to spin, and, as if sensible of their inability so to do, readily turned back when approaching the projected edge; while others at once let themselves down without hesitation; so that it might be known by their motion, when near the brink of the precipice, whether they were endued with the faculty or not. After these animals have spun for some time, their spinning power seems to be for a while lost, but in all those on which experiments have been made, it has been recovered again by keeping them for a few hours among wet mofs.

The fifth variety above-mentioned, or that with feathered black specks, is found in gardens, pastures, and groves, from May till the end of the year, and is the animal which has been recommended to be swallowed by consumptive persons. It is about half an inch in length, and when touched it flicks to the fingers as if dead.

CINERUS. This species is yellowish, with a cinereous belt on the shield and body; it is commonly found in groves, and is about two inches long; body without spots, and beneath it is white.

MARGINATUS. This is cinereous; shield with a dusky break on each side; the body is of a pale bluish colour; it is found on the beech; back with a white ridge, each side of which is bluish-ash; abdomen sometimes spotted black.

RAUCOLATUS. Brown, with black dots on the shield

and lines on the body; it inhabits gardens in Denmark and Germany; it is an inch and a half long.

AUREUS. Yellow, immaculate, with black feelers; it inhabits the groves of Denmark and Norway, is about half an inch long. The body beneath is white, with a black line between the feelers.

FUSCUS. This is of a reddish hue, with a blackish lateral line and back.

TENELOSUS. Greenish, with black head and feelers; is found, early in the spring, in hollows of woods filled with dry leaves; about an inch long; the shield whitish with a yellowish cast.

LANCEOLATUS. Linear-lanceolate and very sharp at each end; the margin surrounded with a membranaceous border; without tentacula or feelers; found on the coast of Cornwall.

LEMAX *Marinus*, in *Zoology*, a name given by some to the *hippatis*, or, as it is commonly termed in English, the *fish-hail*, caught in plenty at the mouths of rivers in Yorkshire, and some other places. See **CYPRINIDÆ**.

LIMAY, in *Geography*, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Mantes; situated on the Seine, opposite to Mantes. The place contains 1520, and the canton 9881 inhabitants, on a territory of 137½ kilometre, in 17 communes.

LIMB, in *Anatomy*, is used to denote certain parts of the human body, proceeding from the trunk. See **EXTREMITIES**.

The limbs, as well as the life of a man, are of such high value in the estimation of the law of England, that it pardons even homicide, if committed *se defendendo*, or in order to preserve them.

LIMBS, *Amputation of*, in *Surgery*. See **AMPUTATION**.

LIMBS, *Artificial*. Under this denomination, surgical writers speak of the various machines and contrivances which have been invented for supplying the place, and in some measure executing the office, of limbs which are naturally imperfect or wanting, or which have been amputated, or otherwise lost. Anciently, it was as much the duty of the surgeon to provide his patient with a wooden leg after amputation, as to cut off the member, which endangered life and could not be preserved. At present, however, the business of furnishing artificial limbs is left almost entirely to the mechanic, though it cannot be denied, that the attention of a judicious surgeon will often be well bestowed in taking care, that the pressure of such machines is contrived to fall as little as possible upon that part of a stump which is most tender, and inclined to ulcerate. The end of a thigh-stump, indeed, can ill bear the effects of pressure, and in this case, it is usual to make the thigh part of the wooden member in the form of a conical box, which is calculated to receive the stump, and at the same time not allow the end of the bone to meet with any material resistance below. The pressure partly falls on the sides of the remaining portion of the thigh, and partly on the pelvis, round which a strap proceeds from the upper part of the machine. The makers of artificial limbs in this metropolis, however, have in general brought their business to great perfection, and such patients as can afford it, may be accommodated with contrivances, which, without being heavy and cumbersome, bear a great resemblance to the natural limb. Artificial hands and arms may also be procured, which have moveable fingers, and by the ingenuity of the mechanism, may be made to perform many little useful offices in grasping and holding things.

LIMBS, *Dislocations of*. See **LUXATION**.

LIMBS,

LIMBS, Fractures of. See FRACTURE.

LIMB, Limbus, the outermost border, or graduated edge, of an astrolabe, quadrant, or the like mathematical instrument.

The word is also used for the primitive circle in any projection of the sphere in plano.

LIMB also signifies the outermost border or edge of the sun or moon, when the middle or disk is hid in an eclipse of either luminary.

Astronomers observe the lower and upper limb of the sun in order to find out its true height, which is that of the centre.

LIMB is also used, among *Botanists*, for the outer edge or border of plants, their leaves and flowers. See PETAL.

LIMBE, in *Geography*, an island in the East Indian sea, about 12 miles long, and 3 broad, near the E. coast of Celebes. N. lat. 1° 18'. E. long. 125° 10'.—Also, a small town or village in the N.W. part of the island of St. Domingo; seven leagues W. by S. of cape François.

LIMBECK. See ALEMNIC.

LIMBERG, in *Geography*, a town of the duchy of Soria; 12 miles S. of Voitsberg.

LIMBERS, in *Artillery*, a sort of advanced train joined to the carriage of a cannon, upon a march. See CARRIAGE.

LIMBER-holes, in a *Ship*, little square holes cut through her floor-timbers, serving to let the water to the well of the pump, which otherwise would lie between those timbers, where the keel rope runs.

Every floor-timber has two limber-holes cut through it; viz. one on each side of the keelson.

LIMBER-boards, are short pieces of plank, which form a part of the ceiling or lining of a ship's floor, close to the keelson, and immediately above the limber. They are occasionally removed, in order to examine and clear the limber-holes.

LIMBER-rope, is a long rope, frequently retained in the limber-holes of a ship, and communicating from one to another, in order to clear them, by pulling the rope backwards and forwards, so as to loosen the sand or dirt by which they may occasionally be choked.

LIMBUO, in *Geography*, a town on the E. coast of the island of Celebes. N. lat. 0° 18'. E. long. 123° 18'.

LIMBOBARYA, a town of Bengal; 30 miles N.W. of Nattore.

LIMBORCH, PHILIP, in *Biography*, a celebrated Dutch divine, was born at Amsterdam in the year 1633. He was educated among the Remonstrants, and had for his instructors among others, Barleius, and Gerard Vossius. Having completed the usual courses of learning, in ethics, philosophy, and the languages, he studied theology under Cancellarius, the successor of Episcopius, in the professorship of that faculty, among the Remonstrants at Amsterdam. Afterwards he went to Utrecht, where he attended the lectures of Gilbert Voetius, and other celebrated divines. In 1654 he undertook the office of minister at Haerlem, from whence he removed to Gouda. In 1660 he published an excellent collection of the correspondence of learned and celebrated men, under the title of “*Epistolæ præstantium, et eruditorum virorum*,” 8vo. In 1684 and 1704 he published new editions of it, greatly enlarged, in folio. In this collection, almost the entire history of the affairs of the Remonstrants may be traced from the time of Arminius down to the synod of Dort. In 1661 he published, in the form of a dialogue, a treatise in defence of toleration, which was exceedingly well received by the friends of liberty. In 1667 he undertook the pastoral charge of the church at Amsterdam, and in the fol-

lowing year he was appointed divinity professor. From this period he wholly devoted his studies to the enquiries connected with his new office, and acquired a high reputation by the manner in which he performed its duties. In the year 1686 he published his system of theology, under the title of “*Theologia Christiana ad Praxin Pietatis ac Promotionem Pacis Christianæ unice directâ*.” It passed very quickly through four editions. In this same year Limborch had a dispute with Orobio, a Spanish Jew, who had escaped from the prison of the Inquisition, and soon after he published the substance of it in a treatise, entitled “*Collatio Amica de Veritate Religionis Christianæ, cum erudito Indæo*.” This treatise very satisfactorily repels the objections which any consistent believer in the Old Testament can advance against the New. He obtained, in 1692, “*The Book of Sentences of the Inquisition of Tholouse from 1307 to 1313*,” which he published, and prefixed to it a history of that horrible and bloody tribunal drawn from the writings of the inquisitors themselves. The title of it is “*Historia Inquisitionis; cui subjungitur Liber sententiarum Inquisitionis Tholosanæ, ab anno 1307 ad 1313*,” 4to. This history is pronounced, by Mr. Locke, to be a work absolutely perfect in its kind; it was translated by Dr. Samuel Chandler into English, in two volumes 4to. with additions by the editor, by Anthony Collins, esq. and by the author. Dr. Chandler prefixed to his edition an introduction, concerning the rise and progress of persecution. In 1694 he converted a young woman to Christianity who had been drawn over to the Jewish religion by a person of whom she had learned the Hebrew language. In 1711 Limborch published his valuable “*Commentarius in Acta Apostolorum et in Epistolâ ad Romanos, et ad Hebræos*.” He died in the month of April 1712, in the seventy-ninth year of his age. A funeral oration was delivered on the occasion by Le Clerc, who, among other things, says, “He was, above all things, animated with the love of truth, and was indefatigable in searching for it, day and night, in the sacred scriptures and the best expositors, and whenever he found it, he adhered to it inflexibly. His piety was pure and ardent, untinged by superstition, or any notions dishonourable to the benevolence of the Deity. As a preacher he was methodical, argumentative, and solid rather than eloquent; and so invariably was he governed by candour, moderation, and prudence, that he never gave offence to any one. In his instructions from his professional chair, he was distinguished by the greatest perspicuity, and the most exact order; to which his memory, which retained whatever he had written, no doubt greatly contributed. His behaviour towards all who had the happiness of being acquainted with him, was so affable, kind, and conciliating, that they saw him with delight, and regretted, when they could no longer enjoy his conversation.” Gen. Biog. Moreri.

LIMBOURG, JOHN PHILIP DE, a physician at Spa, who obtained a great reputation by his knowledge of the properties of the mineral waters, and by the success with which he prescribed them in many obstinate diseases, which had resisted other remedies. He resided at Spa during the season of drinking the waters. He published several works, the principal of which detail the result of his observations on their properties and uses; viz. “*Dissertation sur les Eaux de Spa, soutenue à Leyde, le 7 Août, 1736*,” &c. Liege, 1746, 12mo. “*Traité des Eaux Minérales de Spa*,” Leyden, 1754, 12mo. “*Dissertations sur les Bains d'Eau simple, tant par immersion, qu'en douches et en vapeurs*,” Liege 1757, 12mo. “*Caractères des Médecins, ou l'idée de ce qu'ils font communément, et celle de ce qu'ils devroient être, &c.*” ibid. 1760, 12mo. “*Dissertation sur les Affinités chimiques*,”

chymiques, qui a remporté le prix de Physique de l'an 1753, au jugement de l'Académie de Rouen," *ibid.* 1761, 12mo. "Nouveaux Amusemens des Eaux Minérales de Spa," *ibid.* 1764, 12mo. "Dissertation sur les douleurs vagues, connues sous le nom de goutte vague, et de rhumatisme goutteux, &c.," a prize essay, *ibid.* 1763. "Recueil des Etillets des Eaux Minérales de Spa, de l'an 1764; avec des remarques sur le système de M. Lucas sur les mêmes eaux minérales," *ibid.* 1765. Eloy, Diet.

LIMBOURG, *Duchy of*, in *Geography*, before the revolution, was a province of the Netherlands, bounded on the N. by the duchy of Juliers, on the E. by the electorate of Cologne and duchy of Juliers, and on the S. and W. by the bishopric of Liege; about 30 miles long and 24 broad; but now annexed to France, and forming part of the department of the Ourte. It affords good arable ground, and abounds with a fine breed of cattle. Near the town of Limbourg are found mines of iron, lead, and calamine.

LIMBOURG, late capital of the above-mentioned duchy, now a town of France, in the department of the Ourte, and chief place of a canton, in the district of Malmédy; situated near the river Waze, in a fertile country, on a pleasant mountain. It was formerly fortified in a regular manner, and had a castle, built on a rock, and defended by towers and bastions, constructed of free-stone. When it was ceded to the house of Austria by the treaty of Baden, the fortifications were destroyed. Near it are quarries of different kinds of marble; the adjacent rocks are romantic; the air is healthy, and the inhabitants long-lived. Here is a considerable manufacture of woollen cloth; and in its environs some excellent cheese is made. The town is said to contain 1484, and the canton 12,759 inhabitants, on a territory of 152½ kilometre, in 12 communes; 20 miles E.S.E. of Liege. N. lat. 51° 36'. E. long. 23° 30'.

LIMBRA, a town of Hindoostan, in Guzerat; 35 miles W. of Gogo.

LIMBRY, a town of Hindoostan, in Guzerat; 68 miles W. of Amedabad.

LIMBURG, a lordship and principality of Germany, belonging to the circle of Franconia, but situated in Swabia; extending from S. to N. almost 20 miles, and from W. to E. 18 miles. Also, a town of Germany, seated on the Lahn; 26 miles N. of Mentz. N. lat. 50° 20'. E. long. 8° 3'. — Also, a town and citadel of Germany, called *Habs-Limborg*, which gives name to a county, a fief of the county of Mark, in which it is situated; about 15 miles long and 12 broad; 30 miles E. of Dusseldorp.

LIMBUS, or LIMB, is a term in the *Roman Theology*, used for that place where the patriarchs are supposed to have waited for the redemption of mankind, and where they imagine our Saviour continued from the time of his death to that of his resurrection.

Du-Cange says, the fathers call this place *limbus*, *eo quod sit limbus inferiorum*, as being the margin or frontier of the other world.

LIMBUS is also used by Catholics for the place destined to receive the souls of infants, who die without baptism; who have not deserved hell, as dying in innocence; nor yet are worthy of heaven, because of the imputation of original sin.

LIMBUS *Corollæ*, in *Botany*, the expanded part, or border, of a monopetalous corolla, supported by the tube, and analogous to the *lamina* of each petal in a polypetalous one. See *COROLLA* and *LAMINA*.

LIMBUYAN, in *Geography*, a town on the S. coast of the island of Malacca. N. lat. 12° S. E. long. 123° 36'.

LIML, *lime-stone*, in *Mineralogy*, *Kalkstein*, Germ.

Pierre calcaire, *Chaux carbonatée*, Fr. This species of the carbonates of lime is divided by Werner into four sub-species. 1. Compact lime-stone. 2. Foliated lime-stone. 3. Fibrous lime-stone. 4. Pea-stone.

1. *Compact lime-stone*, is subdivided into common compact lime-stone, and rock-stone.

A. *Common compact lime-stone*; *Gemeiner dichter Kalkstein*, Wern. *Pierre calcaire compacte commune*, Broch. *Chaux carbonatée compacte ou grassière*, Haüy. *Compact lime-stone*, Kirwan. *Tilt kalksten*, Swed.

Among the numerous colours of common compact lime-stone, the most frequent are the various shades of grey, such as smoke-grey, yellowish-grey, bluish-grey, reddish and greenish-grey; it is also seen greyish-white, greyish-black, flesh-red, with some deep tints of red and of yellow; several of these colours often occur in the same fragment, and mostly in such veined, clouded and other delineations which are distinguished by the epithet of *marbled*.

It is mostly found massive, sometimes in rolled, seldom in tabular pieces, frequently with, and almost entirely composed of, extraneous fossils, particularly shells.

Internally it is dull. Its texture is always more or less closely compact, sometimes wax-like; fracture small and fine splintery passing into large and flat conchoidal, and sometimes into even. Fragments indeterminate angular, more or less sharp-edged.

The varieties having a close texture are translucent on the edges.

It is semi-hard, sometimes approaching to soft; brittle; easily frangible.

Specific gravity from 2.500 to 2.700.

It is chiefly composed of lime, carbonic acid, and water; but is seldom without an admixture of some argil and oxyd of iron, and sometimes inflammable matter.

This widely extended substance occurs principally as fletz rock, but it is also found in the transition mountains.

The transition lime-stone is generally more translucent on the edges, and very often exhibits variegated colours, particularly black, smoke-grey, bluish and greenish-grey, and red. It contains, like the fletz lime-stone, petrifications, but mostly of sea animals, the prototypes of which do no longer exist. With regard to the petrification, both in the transition and fletz lime-stone, it is to be observed, that they occur pretty regularly disposed; different strata being generally furnished each with particular genera or even species.

Fletz lime-stone occurs, almost without exception, distinctly stratified; the strata are sometimes very thin, of which we have a remarkable instance in the lime-stone quarries of Sollenhofen, near Pappenheim, in Germany. These strata, which, as Mohs informs us, are very regular and perfectly horizontal, contain the well-known petrifications which are called after that place, but are much less frequently found than is generally imagined.

M. de Bonmon says, that in the Alps of Dauphiné lime-stone is found in strata of no more than one or two inches in thickness, in which case it is not unfrequently mixed with quartz. This lime-stone in tables, called *luyes* in Dauphiné, is employed for enclosing fields: a similar variety is found at Grenoble at the foot of the mountains of Saftinages.

Fletz lime-stone is frequently alternating with subordinate strata of marble, and bituminous marble slate; but in these cases the lime-stone is generally greatly predominating. The exterior of mountains composed of fletz lime-stone is of a peculiar kind; the hills formed by it are seldom conical, but blunt and massy, and intersected by deep valleys.

There are, besides the transition lime-stone, several other formations

formations of compact lime-stone. That called by Werner the *first fletz lime-stone* is the oldest; its lowest stratum is the bituminous and cupriferous marl slate, or the *kupfer-schiefer-fletz*, as it is called by German miners; it extends round a great part of the oldest mountains of Germany, such as the Hartz, the Thuringian forest, Suabia, &c. rests on the old red sand-stone, and is covered by the oldest fletz gypsum, or the variegated sand-stone. It contains, besides the above copper slate strata, several ores of copper, cobalt, heavy spar, &c. being the productions of veins.

The second formation of fletz lime-stone is called *shell-lime-stone*, on account of its abounding in petrifications, which, however, are not peculiar to it, nor do they consist in shells only, for the upper strata contain likewise petrified crabs, vermiculites, species of *asterias*, &c. (See SHELLS, *petrified*, and MARBLE.) It is widely extended, and appears most characteristic in Franconia, Suabia, and Bavaria. This formation is also remarkable, on account of the many caves which occur in it almost in all parts of the world, and many of them filled with the osseous remains of land animals. The most famous of these lime-stone caves are those of Muggendorf and Galenreuth in Bayreuth, at Eichstedt in Franconia, the Baumannshole on the Hartz, those of Dalmatia, Carniola, Hungary, Siberia, &c.

There are some other subordinate formations of fletz-lime-stone; which, however, require to be more closely examined before their characters can be determined with any thing like precision. Of such apparently distinct depositions the following are mentioned by professor Jamieson. 1. A fletz lime-stone, in Poland and Silesia, which alternates with beds of lead-glance and calamine. It was formerly called the calamine formation, and Karsten considers it as subordinate to the first fletz lime-stone, but, according to Werner, it belongs to the second. 2. A deposit of lime-stone between Dresden and Meissen, particularly near Plauen and in the vicinity of Göttingen, which was considered as a third fletz lime-stone formation, but is now classed as a mere variety of the second fletz lime-stone: it is generally sandy, or mixed with clay, and is therefore seldom used as lime, but principally employed as a building stone. It often contains petrifications, such as corallites, ammonites, &c. and sometimes lead-glance is disseminated through it. 3. A lime-stone formation at Weltrau, in Upper Lusatia, containing newer petrifications, such as *pectinites*, *mytilites*, &c.: it alternates with beds of sand-stone, and the whole rests upon alluvial sand. 4. A fletz lime-stone of a reddish-brown colour, frequently containing petrifications; it is horizontally stratified, and contains beds of a variety of alum slate. Also a conchoidal lime-stone of Greece is mentioned as probably constituting a particular formation.

The uses to which compact lime-stone is applied are various; it is principally employed as a building stone, and burnt for making lime and mortar; nor is it less important to the agricultural as a manure, to the miner as a flux for the reduction of ores, to the soap-boiler, tanner, &c.

The fine-grained and variegated varieties of compact lime-stone, many of which are highly valued, are known by the name of *marble*; a term which is more particularly applied to the fine varieties of granular lime-stone, and also given to various mixtures of lime-stone with other substances. See MARBLE.

B. *Roc-stone*; *Rozenstein*, Wern. *Oxiform lime-stone*, Kirw. *Oolite*, Broch. *Chaux carbonatée globulifère*, Haüy. *Mecouite*, *psammite*, &c.

Its colour is generally yellowish-brown, passing into various deeper shades of brown, such as hair-brown, clove-brown; it is also found smoke-grey, yellowish, and reddish-

grey. The colour of the globules is often different from that of the marly mass by which they are cemented together.

It is found massive. It is dull. Fracture fine splintery, a character not easily observable, on account of the fineness of the distinct concretions. Fragments indeterminate angular, blunt-edged.

It consists of spherical, granular, distinct concretions; each of which is generally composed of concentric lamellar concretions, which are either cemented together by a marly substance, or connected by simple contact; the grains vary in size, and are often so minute as to be scarcely distinguishable by the naked eye; the largest are nearly of the size of a pea, but these are seldom seen. In some varieties each globule is an aggregate of several smaller globules.

It is opaque, seldom translucent on the edges.

It is soft and semi-hard; brittle; easily frangible. Specific gravity 2.456 — 2.494, Kirw.

Its chemical character is little different from that of the common compact lime-stone. The variety analysed by Kirwan was composed of 90 parts of carbonate of lime and 10 of alumine, with some oxyd of iron.

This sub-species is much less frequently met with than common compact lime-stone. It occurs, however, in considerable quantities at Brunswick, in Thuringia, particularly in the district of Weimar, in that of Mansfeld, Sangerhausen, Klosterroda, &c. in Tyrol; in England, at Bath, in Derbyshire, at Purbeck.

It occurs chiefly, in more or less considerable beds, in the variegated sand-stone formation, to which it is subordinate, and between the strata of which it is generally interposed with great regularity. It contains no petrifications, nor is it metalliferous.

Roc-stone, being very subject to disintegration, is seldom employed for the purposes of building; but it is in some countries used as a manure. The more compact varieties take a tolerably good polish.

The name of roc-stone is given to this mineral on account of its close resemblance to fish-roses; indeed, the old mineralogists were so far misled by the imitative form of this substance, that they really considered it as the petrified roses of fish.

The origin of the structure of roc-stone is not easily explained; some have considered it as a conglomerate of rolled pieces of lime-stone; others have assigned the same origin to it as to the pea-stone; but Werner considers it as the result of crystallization.

2. *Foliated lime-stone*; *Blättriger kalkstein* of Werner, who divides this sub-species into two kinds: 1. Granular lime-stone. 2. Calcareous spar.

A. *Granular lime-stone*. *Körniger kalkstein*, Wern. *Foliated and granular lime-stone*, Kirw. *Pierre calcaire graine*, Broch. *Chaux carbonatée saccharoïde*, Haüy. *Granular, or saline marble*, *glauary marble*, &c.

Its chief colour is white, often snow-white, greyish, yellowish, and greenish and reddish-white; also bluish, greenish, ash and smoke-grey, and greyish-black; from greenish-white it passes into yellowish and olive-green, and from reddish-white into pearl-grey and flesh-red. Its colours are mostly uniform, but it also occurs sometimes spotted, and with striped and veined delineations; and on their ribs the masses are now and then marked with dendritic figures.

It is massive. Internally it alternates from shining to glistering and glimmering; its lustre being intermediate between pearly and vitreous.

Fracture foliated; sometimes, on account of the smallness of the particles, it appears almost compact and splintery.

tery. Fragments indeterminate angular, not particularly sharp-edged. It occurs almost always in granular distinct concretions, which are coarse, small, and fine-grained.

It is generally translucent; the dark-coloured varieties translucent only on the edges.

It is friable, sometimes hard when mixed with siliceous and argillaceous particles; brittle; easily frangible; seldom elastic.

Specific gravity 2.707 (white Carrara), Muschelbr.;—2.717 (the same), Kirwan;—2.837 (Parian), Briffon;—2.846 (white Saxon), Gellert;—2.836, (elastic var from Campo Lengo), H. de Bellevue.

Pure white granular lime-stone is infusible before the blow-pipe, and only crumbles to pieces. In the charcoal crucible, that of Carrara was found by Klaproth to be burnt to quicklime; while in the clay crucible it was fused into a compact, transparent, hard glass of a light glass-green colour. It instantly strongly effervesces with nitric acid, and when pure is soon dissolved in it without leaving a residue.

Granular lime-stone is almost always of primitive formation; it seldom occurs as transition rock, and scarcely ever as a production of secondary mountains, or if it be found in these, it is never in extensive depositions, but only in beds of not very considerable dimensions. As transition rock it principally occurs on the Hartz; it is found there of a grey colour, and of coarse granular texture.

Primitive granular lime-stone is seldom seen very distinctly stratified; it most commonly occurs in considerable beds in gneiss, mica slate, and clay slate, in which latter the transition lime-stone appears, which, however, principally belongs to compact lime-stone. It is generally simple, but also contains ingredients which are characteristic of it, such as mica, quartz, serpentine, tremolite, hornblende, clay slate, garnets, magnetic iron-stone, blende, &c. Mixed with noble serpentine it constitutes the *verde antico*.

The common varieties are employed for the same purposes as compact lime-stone; the finer are among the most splendid and desirable materials for statuary and architecture, and for the decoration of the interior of houses. See MARBLE, under which article also several of the numerous localities of this sub-species will be given.

Some varieties of granular lime-stone have manifested a considerable degree of flexibility; one of these was discovered by M. Fleuriau de Bellevue, at an elevation of 6000 feet, on Campo Lengo, on mount Gothard. The same phenomenon may be artificially produced by exposing granular lime-stone to a certain degree of heat.

2. *Calcareous spar.* *Calc spar*, Jam. *Kalkspath*, Wern. *Common spar*, Kirw. *Spath calcareus*, Broch.

Its principal colour is white, which is pure and snow-white, or greyish, yellowish, greenish, and seldom reddish; it occurs also olive, asparagus, pistachio and leek-green; greenish-grey, yellowish-grey, honey, ochre, wine, and wax-yellow; flesh red, brown-red, and very rarely rose-red; smoke-grey passing into black; very seldom pearl-grey, and light violet-blue.

It occurs massive and disseminated, also drused and stalactitical, but most commonly crystallized.

The primitive figure of the crystals is an obtuse rhomboid of 101° 32' 13", and 78° 27' 47", according to Hauy; and of 101° 32' and 78° 28', according to Bourron.

The integrant molecule, as observed by Mous. de Bourron, is a trihedral prism with inclined bases. The number of modifications derived from the primitive rhomboid is very considerable; those enumerated in the last mentioned author's very elaborate "Traité de Minéralogie," amounting to no less than fifty-nine.

The figures supposed fundamental by Werner, and from which all the others may be derived, are: the six-sided pyramid, the six-sided prism, and the three-sided prism. The following Wernerian description of the different varieties of calcareous spar is from Janssen's Mineralogy.

1. *The six-sided Prism.*—When perfect it is acute, and three alternate lateral edges are more obtuse than the others. It occurs 1. *Simple*; either erect or inverted. The inverted has three cylindrical concave, and three inwardly bent lateral planes, and on the upper extremity it is flatly acuminate by three planes, which are set on the cylindrically concave lateral planes. 2. *Double*, where the lateral planes of the one are obliquely set on the lateral planes of the other, in such a manner, that the edges of the common basis form a zigzag line, and the more obtuse lateral edges of the one are opposed to the less obtuse lateral edges of the other pyramid. Of this figure the following varieties occur: *a.* The extremity of the pyramid is sometimes more or less deeply and flatly acuminate by three somewhat convex planes, which are set on the more obtuse lateral edges? *b.* The angles of the common base are often more or less deeply truncated; when the truncating planes become so large that they touch one another, the transition into the six-sided prism is formed. *c.* The less obtuse edges are sometimes bevelled, and the extremities sometimes more or less deeply truncated. *d.* If two double six-sided pyramids penetrate one another in the direction of their axis, and one of them is turned around a sixth of its periphery, so that the less obtuse lateral edges of the one crystal come to be opposed to the less obtuse lateral edges of the other, the result is a twin crystal, representing a double six-sided pyramid having three alternate re-entering angles at the common base, where the more obtuse lateral edges are opposed to one another.

2. *Six-sided Prism.*—It occurs usually with three alternate lateral planes broader than the others, and rather acutely acuminate by six planes which are set on the lateral edges, and the acuminate planes meet alternately under more obtuse angles. *a.* The same prism a second time flatly acuminate by three planes, which are set on the alternate obtuse lateral edges of the first acuminations. *b.* When the planes of the second acuminations enlarge so much that those of the first entirely disappear, there results the six-sided prism flatly acuminate by three planes, which are set on the alternate and alternating lateral planes. *c.* The apex of the acuminations is often more or less deeply truncated, which produces the six-sided prism, in which the alternate and alternating terminal angles are truncated. *d.* When the truncation of the apex becomes so large that all traces of the acuminations disappear, the perfect six-sided prism is formed. *e.* When the prism becomes lower, it passes into the six-sided table, which is often extremely thin.

3. *Three-sided Pyramid.*—1. Simple three-sided pyramid, whose summit angle is of various degrees of magnitude, from obtuse to acute. 2. If the angles of the preceding figure are so deeply truncated, that the angles of the truncating planes meet each other, an octahedron is formed. 3. The pyramid is often double; in which case, the lateral planes of the one pyramid are set on the lateral edges of the other. It presents the following varieties: *a.* Flat double six-sided pyramid, which has sometimes convex lateral planes. *b.* If a number of these flat or obtuse pyramids are piled on one another, there is formed a six-sided prism acuminate by three planes, which are set on the alternate and alternating lateral planes. *c.* When this pyramid becomes very obtuse, it gives rise to the lens. *d.* When the summits of the pyramid become less obtuse, and approach to right angles, a figure differing but little from the cube is formed. *e.* When the

the summits become still more acute, an acute double three-sided pyramid is formed. *f.* The acute double three-sided pyramid is sometimes truncated on the lateral edges, sometimes bevelled: in the latter case, when the beveling planes become so large that the original ones are very small, or even disappear, the result is an acute double three-sided pyramid, having its planes length-wise divided; or it is a double six-sided pyramid. *g.* If the summits of the double six-sided pyramid are deeply truncated, it gives rise to the six-sided table, having its terminal planes set on alternately in opposite directions.

Though the preceding description of the different modifications of calcareous spar may possess the merit of speaking to the eye, yet it can by no means supersede the details of a strictly crystallographical investigation; we therefore subjoin a short abstract of the excellent classification given by Count Bournon, in the first volume of his "Traité de Minéralogie" lately published.

All the modifications of crystallized carbonate of lime are by this author divided into, 1, prismatic; 2, rhomboidal; and 3, pyramidal modifications.

I. Prismatic Modifications.

1. *Prism from the edges of the base of the primitive crystal*; or these edges intercepted each by a plane.—Of this, a variety with very short prism occurs in Cumberland and Derbyshire. That with long prism (Chaux carbon. *prismé*, Häüy, pl. 24. f. 10) is likewise found in Cumberland. The variety in which the lateral planes form rhombs, so that the crystal at first sight has the appearance of the garnet dodecahedron, is the scarcest of this modification.

2. *Prism from the solid angles of the base*; these angles of the primitive crystal being intercepted each by a plane.—The chaux carb. *imitable*, Häüy, (ib. fig. 12.) belongs to this modification. It is generally seen in combination with others. Sometimes two of the planes of the pyramid of the primitive rhomboid enlarge at the expence of the third; and sometimes one of them causes, in the same manner, the two others to disappear. Found in Cumberland, Dauphiné, and on the Hartz.

3. *Summit intercepted by a plane perpendicular to the axis*.—This modification seldom occurs in its simple state. The varieties in which this plane is of considerable extent is called chaux carb. *basée* by Häüy (pl. 23. fig. 8.) This is frequently seen united with the preceding modifications; in which case, if the new plane has caused the pyramid of the rhomboid entirely to disappear, the chaux carb. *prismatique*, Häüy, (pl. 24. fig. 14.) is produced, the finest groups of which are found in Cumberland and on the Hartz. Some of the lateral planes of these prisms frequently enlarge, at the expence of the adjoining planes; so that one, two, or even three, entirely disappear. The crystals of the regular hexahedral prismatic variety, from the Hartz, are not unfrequently seen with white opaque surface, and also sometimes to include similar crystals of smaller diameter, which now and then project above the terminal plane of the larger crystal. The prism of this variety is often so short as to represent a thin six-sided table. When both the second and the first modifications are united in the prism, we have the chaux carb. *péridodécédre* of Häüy (pl. 26. fig. 33.)

II. Rhomboidal Modifications.

A. *Obtuse Rhomboids*. Of these, Nos. 5, 6, 8, and 9, have not before been noticed.

4. *Obtuse rhomboid of 114° 19', and 65° 41'*.—One of the most common modifications, and more frequently than all the rest (except the preceding) combined with other

modifications. It is produced by the edges of the pyramid of the primitive rhomboid being replaced each by a plane equally inclining on those by which the edge itself is formed. In its complete state, this modification is the chaux carb. *équiaxe* of Häüy (pl. 23. fig. 2.), which is much more frequently met with than the different passages of the primitive rhomboid into this modification. The planes of this fourth modification are often longitudinally striated; and when they are arrived at their limits, the striae run parallel to the shorter diagonal of the rhomboidal planes.—This is found united principally with No. 2, representing various degrees of elongation of the chaux carb. *dodécédre*, Häüy (pl. 24. fig. 18.); found also as twin crystals in Derbyshire; with No. 1, belonging to the chaux carb. *bifurquée*, Häüy (fig. 17.), chiefly from Cumberland (rare); with Nos. 1 and 2, and with Nos. 2 and 3, chaux carb. *équivalente*, Häüy (pl. 25. fig. 28.), both from Cumberland; with Nos. 2 and 3, and part of the primitive planes, whence it is called chaux carb. *triforme* by Häüy (fig. 26.). The last mentioned variety is from the Hartz; and both the specimen of Häüy and that described by M. de Bournon are remarkable, for having part of the pyramid covered with crystalline matter, which appears to be deposited after the crystal had been completed, and is thus forming a passage into the regular hexahedral prism.

5. *Very obtuse rhomboid of 117° 56', and 62° 4'*.—It is produced by the edges of the primitive rhomboid being replaced each by a plane, which is inclined towards its summit. This has hitherto been found only in combination with other modifications, viz. Nos. 2 and 3. The crystals are all from the Hartz, where red silver ore is sometimes accompanied with them. The variety of calcareous spar, called *en rose*, generally belongs to the complete rhomboid of this modification, as also most of those known by the names of coxcomb and lenticular spar; but they are seldom determinable by the goniometer.

6. *Obtuse rhomboid of 113° and 67°*.—This is easily confounded with the preceding modification. Count Bournon has observed it only in a few instances, combined with the planes of Nos. 1, 2, and 36 (*vide infra*), in crystals from Derbyshire and Cumberland.

7. *Obtuse rhomboid of 107° 3', and 72° 57'*.—This is the result of a decrement of the laminae, similar to that which produces the preceding modification; but the planes thus formed are more inclined on the base of the primitive rhomboid. To this is to be referred Häüy's chaux carb. *quadrirhomboidale*. (Ann. du Mus. d'H. Nat. t. 1. pl. 8. fig. 4.) It is always observed in combination with other modifications, such as with those of Nos. 1, 2, and with those of the primitive crystal. They come from Dauphiné and Derbyshire. This modification has not yet been seen perfect; though nearly so, in a variety which has very narrow planes of No. 1. One variety from Derbyshire, which has the prism of No. 2 combined with this modification, and part of the planes of the primitive rhomboid, might be easily mistaken for prismatic rock crystal, of which it has sometimes the transparency. The planes marked *l* in Häüy's chaux carb. *retrograde*, (pl. 26. fig. 36.) belong to this variety.

8. *Very obtuse rhomboid of 118° 34', and 61° 26'*.—This most obtuse of all rhomboids known to occur in calcareous spar, is the result of a decrement of the crystalline laminae, at the obtuse angles of the planes that form the solid angle of the summit, which is thus replaced by three planes resting on those of the primitive rhomboid. This modification, which is scarce, does not occur in its complete state: besides with planes of the primitive rhomboid, it has been observed

in combination with those of Nos. 1, 3, 5, 8, 41, and 43; most of them from the Hartz. Perhaps some of the very flat lenticular varieties of calcareous spar may be also referable to this modification.

9. *Slightly acute rhomboid of $95^{\circ} 28'$, and $84^{\circ} 32'$.*—This very rare modification is produced by the obtuse angles on the base of the primitive rhomboid being replaced, each by a plane resting on the corresponding primitive planes. It is obvious, that the cleavage of this rhomboid must be different from that of the last mentioned modification, by being on the planes of the summit instead of the base; while that of all the preceding rhomboid, likewise at the base, takes place on the edges. This rhomboid has been observed perfectly in specimens from Siberia; and in combination with the planes of No. 36.

B. *Acute rhomboids.* Nos. 10, 12, 15, 16 and 18—21 of this division are new.

10. *Acute rhomboid of $65^{\circ} 28'$, and $114^{\circ} 32'$.*—The obtuse angles of the primitive rhomboid replaced each by a plane, as in the preceding; but being the result of a more rapid decrement of the laminae, its axis is three times longer than that of the primitive rhomboid. Occurs, though rarely, in Derbyshire, both in its complete state, and in combination with remains of the planes of No. 2.

11. *Acute rhomboid of $45^{\circ} 34'$, and $134^{\circ} 26'$.*—The result of a decrement on the fine angles as in the preceding, but the decrement producing a rhomboid much more acute. It is the *chaux carb. contracta* of Haüy (pl. 23, fig. 5.) one of the most common rhomboids that occur in calcareous spar. It occurs perfect, sometimes with traces of the primitive planes, and in combination with Nos. 1, 2, 3, 4, and 36. Is found in Derbyshire, Cumberland, at Grenoble in France, on the Hartz, &c. When the planes of the rhomboid of this modification are combined with those of the common acute pyramidal dodecahedron, No. 36, they replace the solid angles of the base of this dodecahedron in the form of an elongated trapezoid.

12. *Acute rhomboid of $40^{\circ} 26'$, and $139^{\circ} 34'$.*—Decrement on the same angles as in the preceding, to which it approaches closely. Occurs mostly in its complete state in Derbyshire, and has been seen combined in the same crystal with planes of the primitive rhomboid, and Nos. 1, 14, and 30, in which latter its planes are placed nearly in the same manner as those of the rhomboid of the preceding modification.

13. *Very acute rhomboid of 15° and 165° .*—Decrement on the same angles as in the preceding modifications, but giving origin to a much more acute rhomboid. Count Bournon has observed it in its complete state. It is seldom seen, and it is difficult to preserve it, on account of the great fragility of the fine termination of the crystals. Combinations of the planes of this and No. 4 occur in Derbyshire, on the Hartz, &c. and in Cumberland, generally on crystals of sulphate of barytes; the one called *chaux carb. contracta* (Haüy, pl. 24, fig. 20.) belongs to it. Fine groups of this modification in its complete state have been found in Westmoreland; and in the same specimen, combined with planes of the very acute pyramidal dodecahedron, No. 54.

14. *Slightly acute rhomboid of $87^{\circ} 42'$, and $92^{\circ} 18'$.*—This is the *chaux carb. cuboide* of Haüy, (pl. 23, fig. 7.) It occurs complete, with planes of the primitive rhomboid, and combined with the planes of several other modifications, such as Nos. 1—4, and No. 15, in Languedoc, at Strontian, Bath, in Derbyshire, and on the Hartz. This modification, combined with the planes of No. 3, is the *chaux carb. apophane* of Haüy, (pl. 24, fig. 15.)

15. *Acute rhomboid of $84^{\circ} 26'$, and $95^{\circ} 34'$.*—This rhom-

boid, the preceding, and all the following, are the result of a decrement of the crystalline laminae on the obtuse angles of the base; and the cleavage in all of them takes place at the summit, and on the edges of the crystal. Though combined with most of the other modifications, the planes of this rhomboid have never been mentioned by crystallographers, a circumstance probably owing to their smallness, and their having been confounded with the preceding, from which it is, however, easily distinguished, even without the assistance of the goniometer. It is sometimes found in a complete state on the Hartz, and at Strontian in groups, accompanied with stilbite and cross-stone, or harmotome, and in combination with the planes of Nos. 1—5, and also with the remains of those of the primitive rhomboid.

16. *Acute rhomboid of $81^{\circ} 19'$, and $98^{\circ} 41'$.*—This is oftener seen in its complete state than combined with the planes of other modifications, such as those of Nos. 1, 2, 3, 4, and 36; it also occurs with traces of the primitive rhomboid. Most of these were brought from the island of Ferroe, and from Scotland; the former mostly in groups, with stilbite zeolite, the others with analime zeolite. The variety in which it is combined with No. 4, came from Castagna-moro, in Italy. Their gangue, in the above places, is a wacke like rock.

17. *Acute rhomboid of $75^{\circ} 31'$, and $104^{\circ} 29'$.*—This is the *chaux carb. inverse* (Haüy, pl. 23, fig. 3.), so called because this rhomboid is, as it were, an inversion of the primitive. Next to No. 14, it is the most common of all the modifications of calcareous spar; but a circumstance worth remarking is, that it scarcely ever occurs in any other but shell lime-stone; while the reverse prevails with regard to the primitive rhomboid which, in its perfect state, is seldom found in any but the older formations of lime-stone. The name of *marialique*, given to this rhomboid by Ronré de Pisle, is derived from the just mentioned mode of occurring. The complete rhomboid frequently occurs in veins at Bath, in Derbyshire, and lining hollows of shell-marble in several other parts of Britain. In still greater perfection it is found, together with various combinations of the planes of other modification, in the shell lime-stone of Conson, near Lyons, and in those of Vougy, near Roanne, in Forez; in the former of these places it is generally seen in the interior of siliceo-calcareous geodes; in the latter in geodes of black, earthy, and compact black manganese, with manmillary internal surface. It has been observed by M. de Bournon combined with the planes of the primitive rhomboid, and with those of Nos. 1 to 4, and Nos. 11, 14, 36, 37, and 49. That with narrow remains of the primitive planes is Haüy's *chaux carb. unitaire* (pl. 23, fig. 9.); that with remains of the primitive planes, and those of the prism No. 2, has been described by the same crystallographer under the name of *chaux carb. unibinaire* (Ann. du Mus. Par. vol. i.); that with the planes of the same prism No. 2, and with those of No. 3, is Haüy's *chaux carb. persiflante* (pl. 25, fig. 29.); the same with additional remains of the planes of No. 4, is his *chaux carb. coordonnee*; and a variety in which this rhomboid is combined with narrow planes of Nos. 1, 2, 3, 4, and 37, is described by him under the name of *chaux carb. quadruplante*. (Ann. du Mus. vol. i.)

18. *Acute rhomboid of $70^{\circ} 18'$, and $109^{\circ} 42'$.*—This rhomboid is very rare, and has been seen in combination only with the planes of the prism No. 2, accompanied by planes of Nos. 23, 37, 39, and of the primitive rhomboid. These crystals occur in Cumberland and in Derbyshire.

19. *Acute rhomboid of $61^{\circ} 12'$, and $118^{\circ} 48'$.* This has been observed by count Bournon, in its complete state, in 2

mafs of brown iron-ftone; and alfo in combination with the planes of the primitive rhomboid and thofe of Nos. 1, 2, 3, 4, 11, and 36. The cryftals exhibiting this modification are, with a few exceptions, all from Derbyfhire.

20. *Acute rhomboid of 55° 34', and 124° 26'.*—This rhomboid, which has been obferved complete, and in combination remains of the primitive planes, and thofe of Nos. 2 and 3, is of ftill rarer occurrence than the preceding. Found in Derbyfhire and Cumberland. The preceding, and the next modification, fometimes exhibit, underneath their pyramidal edges, the planes of the primitive rhomboid, which, efpecially when of a different tint from the reft, are vifible through the fubftance of the cryftal; a phenomenon produced by a fuperpofition of cryftalline matter on the cryftal already formed.

21. *Acute rhomboid of 50° 54', and 129° 6'.*—This occurs both fimple and combined with other modifications, fuch as Nos. 1, 2, 3, 4, 11, 17, and 46, in the Hartz, in Cumberland, and more frequently in Derbyfhire. It is often feen to accompany ftalactitical varieties of calcareous fpar.

22. *Very acute rhomboid of 37° 31', and 142° 29'.*—This is the chaux carb. *mince* of Haüy (pl. 23, fig. 6.) It is, like the preceding, not unfrequently met with, particularly as accompanying ftalactitical lime-ftone; it occurs as often in a complete ftate as combined with the planes of other modifications, among which are Nos. 2, 3, 4, 7, 11, 14, and 46. They are principally found in Derbyfhire. The variety which is combined with the planes of No. 4, has been defcribed by Haüy under the name of *ministe* (Ann. du Mus. vol. i.); and that with the planes of No. 11, and remains of the primitive planes, is called by the fame cryftallographer chaux carb. *tri-rhomboidale* (Min. pl. 25, fig. 17.); that with additional traces of the planes of No. 7, is his chaux carb. *quadrirhomboidale* (Ann. du Mus. vol. i.). When the planes of this variety, and thofe of Nos. 11 and 3, are united at the extremities of the prismatic modification No. 2, it is Haüy's chaux carb. *annulaire* (ibid.)

23. *Extremely acute rhomboid of 12° 6', and 165° 54'.*—This is the moft acute of all the rhomboids that belong to calcareous fpar. It is feldom feen in its complete ftate, both on account of its minutenefs and its extreme fragility; M. de Bournon has, however, obferved it feveral times on the groups of calcareous fpar from the Hartz, which are confidered as filiform and indeterminable. The combination of the planes of this with thofe of No. 4, is named chaux carb. *dilatée* by Haüy (pl. 24, fig. 21.), which occurs alfo as made; that with traces of the planes of Nos. 3 and 17 is the fame cryftallographer's chaux carb. *hyperacide* (pl. 25, fig. 30.); and that with Nos. 4 and 7, his chaux carb. *retrograde* (pl. 26, fig. 36.) It occurs alfo with the planes of feveral other modifications. This rhomboid might eafily be miftaken for that of No. 13, which is, however, the refult of quite a different decrement of the cryftalline laminae, and confequently has a different cleavage.

III. Pyramidal Modifications.

The feveral pyramidal dodecahedrons belonging to this divifion, are here diftinguifhed from each other by the meafure of the folid angle of their fummit, taken on two oppofite edges of the pyramid.

A. *Pyramidal obtufe dodecahedrons*—The modifications of this fub-divifion of pyramidal dodecahedrons are, upon the whole, very rare, and almoft peculiar to England, where they occur in Derbyfhire, Cumberland, and Durham. When the planes of feveral of thofe modifications are combined in the fame cryftal, their narrownefs, together with the very obtufe

angles they form with one another, fometimes produces curvilinear planes, efpecially when they are, at the fame time, combined with the planes of feveral of the rhomboidal modifications.

The following ten modifications, with the exception of Nos. 27 and 30, have not been noticed before.

24. *Obtufe pyramidal dodecahedron of 134° 28'.*—This modification (as well as thofe that follow), is the refult of a retrogradation of the cryftalline laminae, along, and parallel with, the edges of the pyramids of the primitive rhomboid, replacing each of thefe edges by a double plane or bevelment. Three of the edges in each pyramid of this modification muft, therefore, be exactly in the fame direction with thofe of the primitive rhomboid. It has not been obferved either in its paffage from the primitive rhomboid, or as complete dodecahedron, but only in combination with very fhort planes of the prifm No. 2 (from Cumberland); with thofe of Nos. 2, 4, and 36, in a pyramidal cryftal from Derbyfhire; and with thofe of Nos. 2 and 35, from the fame county.

25. *Obtufe pyramidal dodecahedron of 126° 51'.*—This modification, if it exifted in a complete ftate, would exhibit pyramids with planes forming ifofceles triangles, and confequently with all the angles of the common bafe on the fame level. M. de Bournon has but twice obferved this modification; and in both cafes combined with the planes of feveral other modifications, among which thofe of the prifm No. 2 are the moft apparent. From Derbyfhire.

26. *Obtufe pyramidal dodecahedron of 124° 36'.*—This is of much more frequent occurrence than the preceding, from which it differs effentially, in having fcalene triangles. The complete dodecahedron comes from Derbyfhire; a combination of its planes with thofe of No. 2 from Cumberland. In Derbyfhire it is alfo found combined with the planes of feveral other modifications, of which thofe of Nos. 2 and 36 are the moft characteristic.

27. *Obtufe pyramidal dodecahedron of 121° 26'.*—The planes that terminate Haüy's chaux carb. *fonftrodive* (pl. 26, fig. 37.) belong to this modification. They are alfo feen in his chaux carb. *furcompofée* (pl. 28, fig. 50.), in which five modifications are combined. Cryftals with planes of this dodecahedron are common in Derbyfhire and Cumberland, where it occurs combined with the planes of feveral other modifications. The complete dodecahedron is fcarce.

28. *Obtufe pyramidal dodecahedron of 118° 26'.*—Has not yet been found in a complete ftate. The fimpleft combination is that with the very fhort planes of the prismatic modification No. 2. But it generally occurs together with the planes of feveral other modifications, fuch as with Nos. 4, 7, 11, 27, 28, and 36, and in fome of thefe alfo, with remains of the planes of the primitive rhomboid. Found principally in Derbyfhire and Cumberland.

29. *Obtufe pyramidal dodecahedron of 117° 25'.*—Differs but little from the preceding. It has not been found in a complete ftate, nor are its planes often feen combined with thofe of other modifications; among thofe figured by M. de Bournon are Nos. 2, 15, 17, and 36. The cryftals which exhibit its planes are moftly from Derbyfhire.

30. *Obtufe pyramidal dodecahedron of 115° 17'.*—Its planes are represented in Haüy's chaux carb. *dijointe* (pl. 26, fig. 38.), in which it is combined with thofe of Nos. 2 and 36. In the fame author's chaux carb. *binénaire* (Ann. du Mus. vol. i.) it is feen without the planes of the prismatic modif. No. 2, but with thofe of No. 30; and his chaux carb. *additive* (ibid.) is the bifonare, augmented by the planes of No. 4. Thefe cryftals are faid to come from Derbyfhire. M. de Bournon has not himfelf feen cryftals with planes of this modification.

31. *Obtuse pyramidal dodecahedron of 100° 24'.*—The planes produced by the retrogradation of the crystalline laminae replace the edges of the primitive rhomboid, but instead of being parallel to them, as in the preceding modifications, they become narrower towards the summit of the rhomboid. The two pyramids of this dodecahedron are, like those of No. 25, composed of isosceles triangles, whence the angles of their base must be upon a level. It has not yet been observed in its complete state; but in a variety composed of its planes and those of Nos. 35 and 2, M. de Bournon has seen it terminate the crystal in a very regular manner. It has also been observed in a crystal in which the planes of No. 2, and in another in which those of No. 36, are predominant. The crystals exhibiting the planes of this modification are rare, and have been found only in Derbyshire and Cumberland.

32. *Obtuse pyramidal dodecahedron of 101° 6'.*—This has not been seen complete, but in combination with the planes of several other modifications producing very complicated crystals. They occur in Derbyshire, but rarely. The cleavage of this dodecahedron takes place at the base on the less obtuse edges.

33. *Obtuse pyramidal dodecahedron of 95°.*—The crystals in which are seen the planes of this modification occur but seldom, and are still more complicated than those with the planes of the preceding modification. One of the two crystals figured by M. de Bournon comprehends 72, and the other no less than 84 planes, of which those of the prismatic modification, No. 2, are the principal ones. They were found in Derbyshire. The cleavage of this dodecahedron is the same as that of the preceding modification.

B. *Acute pyramidal dodecahedrons.*—The following modifications, with the exception of Nos. 34, 36, 39, 48^s and 50, are all new.

34. *Acute pyramidal dodecahedron of 88° 53'.*—The planes of this dodecahedron are the result of a decrement of the crystalline laminae along the edges of the base of the primitive rhomboid: the cleavage at the summit on the more obtuse edges. Their planes are marked in Haüy's figure of his chaux carb. *ligiminte* (pl. 27 fig. 49). Besides in this combination, (in which the planes of No. 36, are the most prominent,) M. de Bournon has observed them with the planes of Nos. 2, 29, and 34, in two crystals from Cumberland, where also the complete dodecahedron has been found. The planes of this modification are of rare occurrence.

35. *Acute dodecahedral pyramid of 78° 40'.*—This is far less scarce than the preceding modification, with which it agrees in the nature of the decrement and the cleavage. Has not yet been observed in its complete state. Its planes are represented in Haüy's figure of chaux carb. *ascendante* (pl. 27, fig. 44, n), in which they are combined with those of Nos. 2 and 11. Another crystal has been described by Haüy, under the name of *sousquadruple* (Ann. du Mus. vol. ii.), which differs from the latter in having also traces of No. 28. The dodecahedron has not been seen in its complete state, but our author possesses crystals in which the two pyramids are separated from one another only by short planes of the prismatic modification No. 2. Besides this, its planes have been observed in combination with some other modifications. These crystals have been found in Derbyshire.

36. *Acute pyramidal dodecahedron of 48° 22'.*—This is Haüy's chaux carb. *mitigative* (pl. 40, fig. 70), a modification which, both in its complete state, and in conjunction with the planes of other modifications, is of most frequent occurrence in the crystals of calcareous spar. We shall mention the more interesting varieties.

When, in the progress from the primitive rhomboid into this dodecahedron, only small planes of the former remain at the top of the pyramid, it is the chaux carb. *linaire* of Haüy (pl. 24, fig. 11.) The complete dodecahedron is still more common than this; it is sometimes found with planes of the pyramids unequal, and not meeting in a point; also as macle. Combined with small planes of No. 2, it is Haüy's chaux carb. *bifalterne* (pl. 25, fig. 23); which likewise occurs as macle. When the planes of the prismatic variety are more considerable than in the just-mentioned variety, and, consequently, hexagonal, it is the chaux carb. *prism* of Haüy (pl. 25, fig. 24); this is very common. If, in addition to the latter, small planes of No. 4, are seen, it is the chaux carb. *analogique prism* of Haüy (pl. 26, fig. 35); from which the chaux carb. *analogique disjointe* (Haüy, pl. 26, fig. 38.) only differs in the magnitude of the planes of Nos. 4 and 36. The combination of Nos. 2, 4, and 36, is also sometimes seen in the shape of that beautiful macle called "heart-shaped calcareous spar," and explained and figured by M. de Bournon. The prism of No. 2, having planes of this 36th modification, together with remains of the primitive planes at the summits of the pyramid, is Haüy's chaux carb. *linaire* (pl. 25, fig. 26.) In combination with the prism of No. 1, and with Nos. 1 and 37, this dodecahedron is seldom found; in the latter the line which separates the pyramidal planes from the prism is sometimes imperceptible, so that the crystal appears composed of curvilinear planes.

A variety, remarkable on account of its simplicity, is the chaux carb. *analogique* (Haüy pl. 26, fig. 34.); it is likewise composed of the planes of this modification, and those of Nos. 2 and 4, forming altogether a crystal of 24 trapezoidal planes, not unlike those of the leucite, except that in the former the planes are of three different dimensions.

This modification is also often seen in combination with the planes of No. 11; the variety in which these latter have much increased in size at the expense of the former, is Haüy's chaux carb. *linaire* (pl. 25, fig. 25.); the same crystal is also observed as macle. A similar variety, but which contains also narrow planes of Nos. 4 and 17, is the chaux carb. *doublante* of the same crystallographer, (pl. 27, fig. 47.)

The pyramidal variety of this modification with planes of Nos. 17 and 11, is Haüy's chaux carb. *prism* (pl. 27, fig. 41.); and a similar one, but with the planes of No. 2 instead of 11, is the same author's chaux carb. *emouffée* (pl. 26, fig. 40.); the latter occurs also as macle.

Many more combinations of the planes of this modification, with those of others, are described and figured by count Bournon; among others a crystal, composed of seven modifications, contains, in all, sixty planes, and another, composed of eleven modifications, exhibits no less than 96 planes. The same author has illustrated this modification by 129 figures.

37. *Acute pyramidal dodecahedron of 40° 14'.*—Though the dodecahedron of this modification is considerably more acute than that of the preceding modification; yet it appears to have hitherto been confounded with it. It has been found in combination with the planes of the primitive rhomboid, and those of Nos. 36, 2, and 11, and also in its complete state. The crystals exhibiting this modification are pretty large. They have been found only in the Dauphiné Alps of Loisan, and in Derbyshire.

38. *Pyramidal dodecahedron of 37° 5'.*—This might easily be mistaken for the dodecahedron of the preceding modification. It has not yet been observed in its complete state, but

in combination with the planes of Nos. 2, 3, 15, 17, 22, and with remains of the planes of the primitive rhomboid. Has been found in Hungary, and other places; but does not appear to occur in England.

39. *Pyramidal dolomite* of 29-5°.—The complete double form occurs in Germany; nearly completely, with planes of No. 17 at the points of the pyramids, it is Hädy's *chaux carb. subulnaire* (pl. 25, fig. 22); with the summit intersected by N. 3, and with trapizoidal planes of No. 2, it constitutes the fine crystallographer's *chaux carb. subulnaire* (ib. fig. 31.); its planes are also seen in his *chaux carb. zéolite* (pl. 29, fig. 39.) in combination with those of No. 1, and of No. 17, which latter are the characteristic planes. Also the variety described by Hädy under the name of *quartziforme*, (Ann. du Mus. vol. ii.) has small planes of this 39th modification, which has hitherto been found principally in Germany.

45. *Acute pyramidal Lohschtron* of $26^{\circ} 34'$ —This dodecahedron is not unfrequently seen in its complete state, but its points, on account of their great fragility, are generally broken. It occurs in Germany, from which country, and from Derbyshire and Cumberland, are also procured groups of crystals, including the planes of this modification, in combination with others, such as Nos. 1, 2, 3, 17, 19, 21, 22, 30, and 35.

31. *Acute pyramidal dodecahedron of 15 53'.*—This is the last, and at the same time the most acute, of the series of pyramidal dodecahedrons produced by a decrement along the edges of the base of the primitive rhomboid, and consequently with cleavage at the summit on the more obtuse edges of the pyramid. This dodecahedron occurs complete, but, on account of its great fragility, is generally seen in a broken state; sometimes two opposite planes of the pyramid, having increased in size, so that they meet no longer in a point, give rise to coniciform pyramids. Nor is it uncommon to see four opposite planes in the same case. Such crystals bear great resemblance to certain varieties of arragonite, from which they are, however, easily distinguished by their much greater fragility, and by their lamellar structure. It has been observed with vestiges of the primitive planes, and in combination with those of several other modifications: in one crystal there are no less than 60 planes, being the result of seven different modifications. The crystals exhibiting planes of this modification are mostly found in Cumberland, Derbyshire, and on the Hartz.

42. *Acute pyramidal dodecahedron* of 67° 55'.—With this begins the series of those dodecahedrons which are the result of a decrement of the laminae at the acute angles, on the life of the primitive rhomboid. Hence the cleavage takes place at the summit on the less obtuse edges. Is found in its complete state, and combined with the planes of Nos. 36, and 36 and 2, in Derbyshire; but belongs to the more feeble modifications of calcareous spar.

43. *Acute ditetrahedral pyramid* of $62^\circ 36'$ —This has been found in a complete state in Derbyshire, where, as well as in Cumberland, it occurs also combined with the planes of several other modifications, for example, in some instances, very complicated crystals, such as that of fig. 476 in the work before us, the 102 planes of which are the result of eleven modifications.

44. *Acute dodecahedral pyramid* of $61^{\circ} 47'$.—Though the solid angle of the summit of this dodecahedron differs but little from that of the preceding modification, yet there is a great difference in the inclination of their planes: in the preceding dodecahedron these meet each other under three angles of $158^{\circ} 22'$, and three others of $95^{\circ} 40'$, while in this 44th modification they meet three of them under an angle of 140°

42', and three under one of 112° 44'. The complete decahedron of this modification is scarce, but occurs in Derbyshire. In combination with the planes of other modifications, particularly with Nos. 2 and 14; 3, 14, and 47; 2, 4, and 50, it is found in Derbyshire and Cumberland; and combined with planes of several other modifications, count Bourne has seen it among the crystals of calcareous spar that accompany the silver ores of Potosi; one of these crystals, the result of eight modifications, has 46 planes.

Hall's chaux carb. *summe* 1. des Min. N^o. 1860. n^o. 1.
approches very near this modification in the measurement of
its angles.

45. *Acute pyramidal dodecahedron of 56° 30'*.—Might easily be mistaken for the dodecahedron, No. 36, in which, however, the cleavage takes place on the more outside edges. The dodecahedron in its complete state has been found in Derbyshire, where this modification occurs in combination with the planes of several others; the most complicated among them is a crystal, produced by ten modifications, five of which belong to rhomboid, and four to dodecahedrons, which, together with the planes of the prism No. 2, form a crystal of 84 planes.

46. *Acute pyramidal dodecahedron of 49° 23'.*—Resembles the dodecahedron, No. 43, with regard to the inclination of its planes to each other; but it is much more acute. On the other hand it approaches near the dodecahedron, No. 56, in the measurement of the solid angle of its summit; but in this the inclination of the planes is different, not to mention the difference in the cleavage. This dodecahedron in its complete state is very scarce, it has, however, been found in Derbyshire and Cumberland; the combinations of its planes with those of other modifications, such as Nos. 1, 2, 3, 4, 6, 17, 36, and those of the primitive rhomboid, are more frequently met with in those parts of England.

47. *Acute pyramidal dodecahedron of* $45^{\circ} 2'$.—This appears to be peculiar to the same places, in which the crystals with the planes of the preceding modification are found. The complete dodecahedron is seldom seen. It is most frequently found in combination with the prism No. 2: the angles of three alternate edges being very obtuse, its pyramid appears almost triangular. These crystals are in general very transparent and beautiful.

48 *Acute pyramidal dodecahedron of 44° 30'.*—This is but little more acute than the dodecahedron of the preceding modification; but the planes of the latter meet each other, three under an angle of 163° 50', and three under one of 84°; while in this 48th modification the same planes meet three under 150° 8', and three under 57° 12'. The dodecahedron in its complete state has not yet been found. Its planes occur in crystals from Cumberland and Derbyshire, in combination with those of Nos. 2, 14, 32, 36, and 45.

48*. *Acute pyramidal dodecahedron of 41° 31'*.—The planes of this modification are those marked *x* in the figures of Haidy's chink carb. *prismatic* (pl. 27, fig. 42.), *all-faces* (ib. fig. 46.), and *complané* (ib. fig. 43.)

49) *Trigonal trisphenoidal*, rhedron of 50 9. — The dodecahedron of this modification in its complete state is from Hungary. Combined with the planes of several other modifications, it occurs principally in Derbyshire; one of the crystals from thence, figured by count Bournon, is composed of 90 planes, being the result of nine modifications.

50. *Acute pyramidal dodecahedron of 25° 25'*.—To this probably belong the pyramidal planes of Huüy's *chaux carb. acutangule*. This modification has hitherto been principally found on the Hartz, it occurs however also, combined with the planes of several others, in Derbyshire and other parts

of England; the crystals that exhibit its planes frequently accompany it. It is a crystalline carbonate of lime. The complete dodecahedron has not yet been found.

51. *Acute pyramidal dodecahedron of 14° 30'.*—The planes of the very acute pyramids of this modification are of rare occurrence; and in its complete state the dodecahedron has not been seen at all. The crystals from Derbyshire, on which its planes have been observed, are the result, some of six, others of seven and eleven, different modifications.

52. *Acute pyramidal dodecahedron of 18° 26'.*—Though this and the two following dodecahedrons are, like those of the preceding modifications, the result of an intermediate decrement of the crystalline laminae on the acute angles of the planes at the base of the primitive rhomboid, yet they differ from the latter in the cleavage, which takes place on their more obtuse edges. This dodecahedron has not yet been found in its complete state; in combination with the planes of several other modifications, of which those of No. 36 are the most considerable, it is found in Derbyshire.

53. *Acute pyramidal dodecahedron of 16° 35'.*—M. de Bournon has observed the planes of this modification only in two crystals from Strony, where they sometimes accompany red silver ore. This is undoubtedly the feeblest of all modifications of calcareous spar, and one of the few that are not found in England.

54. *Acute pyramidal dodecahedron of 14° 4'.*—This is the most acute of all dodecahedrons hitherto observed in calcareous spar. It differs but little in this respect from that of No. 51; but independently of the considerable difference in the respective inclination of their planes to each other, the cleavage of the former is on the less obtuse edges, while that of this modification takes place on the most obtuse edges. M. de Bournon has observed the planes of this modification in two varieties only; the one is the dodecahedron in its complete state; the other exhibits its planes combined with those of No. 13, which latter happens to be the most acute of all rhomboids hitherto observed of this substance. Both varieties were found in Westmoreland.

55. *Acute pyramidal dodecahedron of 34° 12'.*—This dodecahedron, like those of Nos. 25 and 31, is composed of isosceles triangles. Count Bournon has observed this rare modification in a few crystals from Derbyshire, in combination with the planes of the primitive rhomboid, and those of Nos. 2 and 4.

IV. Dodecahedral prismatic Modification.

56. *Dodecahedral prism formed at the solid angles of the base.* (not before described). Its planes are produced by a retrogradation of the crystalline laminae on the solid angles, so as to replace each of them by two planes which meet under an angle of 142° 2'. Its planes are found combined with those of the hexahedral prism No. 2, which give the crystal the form of a prism of 18 sides; in other crystals which, besides the just mentioned planes, comprise also those of No. 1, the prism is composed of 24 sides. It has been likewise found in combination with the planes of six different modifications, four of which belong to dodecahedrons, one to the prism of No. 2, and one to No. 56, producing in all 66 planes. Another variety has been observed by Count Bournon, which, in addition to the planes of the last-mentioned variety, contains also those of the prism No. 1, and is consequently composed of 72 planes. This modification, which has been found in Cumberland, is rare, but it is not improbable that its planes may be those of several of the curvilinear varieties already mentioned, but which cannot be determined by the goniometer.

The crystals of calcareous spar are variously aggregated,

and often so deeply imbedded, that their summits only are visible. They occur of all degrees of magnitude, from minute to 14 inches in length; their surface is generally smooth, sometimes streaked or drused. Externally from shining and splendid, to dull, sometimes pearly; internal lustre from splendid and specularly splendid, to shining and glistering; it is mostly a vitreous lustre, the intensity of which is generally in proportion with the transparency of the crystal.

Fracture foliated, rarely curved foliated; fragments rhomboidal. The massive is generally found in large-grained distinct concretions, but also sometimes in testaceous, wedge-shaped, and diverging, more or less streaked prismatic concretions.

Transparency both of massive and crystallized calcareous spar is various; the former is however generally only translucent, while the crystals are mostly semi-transparent and transparent; and these possess the double refraction in a high degree.

It is semi-hard, between gypsum and fluor spar, or, (as Count Bournon characterises its hardness,) just scratched by common brags. It is brittle, easily frangible.

Specific gravity 27.17 as a mean. Bourn.

Some varieties, especially that of brownish-yellow colour, and part of those found in the shell marble of Derbyshire, are phosphorescent when laid on a hot coal. The same quality has been observed, by Schumacher, in varieties from Norway.

Its chemical characters agree with those of the preceding sub-species. The purest Iceland spar is composed of

Lime	55.0	55.5
Carbonic acid	34.0	44.
Water	11.0	0.5
	100 Bergm.	100.0 } Phillips Phil. Mag. xiv.

This sub-species is found in most parts of the world; but most abundantly it occurs in England (where almost all modifications have been found), in Saxony and France. Certain crystal-forms appear to be peculiar to certain countries or localities; but this requires farther observations.

With regard to the Iceland spar it should be remarked, that this very pure massive variety of calcareous spar, is far from being peculiar to that island; at Pergine, in Italy, as we are told by Buch, the same occurs in mica slate, as masses sufficiently large to be cleft into rhomboids of upwards of two feet in length.

Calcareous spar is, almost without exception, the production of particular repositories; it is never seen to form independent beds or strata. It occurs venigenous in the rocks of almost all formations; in the oldest; in Switzerland and the Pyrenees, it is accompanied with feldspar, rock-crystal, &c. Also frequently in various metalliferous veins in gneiss, mica slate, clay slate, sienite, porphyry, more seldom in granite, frequently in grauwacke, and with ores of cobalt and copper, in the older fletz lime-stone. The newer fletz lime-stone is sometimes traversed by veins entirely composed of calcareous spar.

The minerals usually accompanying calcareous spar are granular and compact lime-stone, brown spar, quartz, feldspar, barytes, fluor spar, clay slate, chlorite, iron and copper pyrites, spathose iron, brown iron-stone, galena, blende, grey copper ore, malachite, &c.

3. Fibrous lime-stone.

This sub-species is divided into two kinds, *a*, common, and *b*, stalactitical fibrous lime-stone (*Kalkstein*, Wern.)

A. Common fibrous lime-stone Gemiciner safriger Kalkstein, Wern. *Satin spar*.

Its

Its colours are white, greyish, reddish and yellowish-white.

It occurs massive.

Internally it is between glistening and shining, with a pearly or satiny lustre.

Cross-fracture compact splintery; longitudinal fracture straight or wavy, fibrous (which may be considered as indeterminable crystals) are either strongly adhering to each other, and parallel, or partly detached, and tapering; they have also been seen reticularly aggregated. Fragments in most varieties splintery, also flattened fibrous; strongly translucent. Hardness rather less than that of calcareous spar, which it resembles in the remainder of its characters.

Its constituent parts were found by Mr. Pepys to be

Carbonic acid	47.6
Lime	50.1
Water and loss	2.3

100.0 Phil. Mag. xñ.

It is a product of veins.

The finest variety of fibrous lime-stone is that of Cumberland, to which the name of fatin spar is peculiarly applicable. It forms veins or trunks of a few inches thick, in a calcareous clay; the falbands or lifts of these small veins are thin layers of a blackish clay slate mixed with iron pyrites. This variety, which has sometimes a beautiful pale rose red tint, and perfectly pearly lustre, is cut and polished, and employed for inlaid and other ornamental works; when cut en cabochon, it sometimes passes for white cat's-eye, a name which is also sometimes erroneously, sometimes fraudulently, given to pieces of fibrous gypsum, cut in the same manner.

M. de Bourbon has described a pretty variety of this substance from Matlock in Derbyshire; it forms a very light, cellular mass, in which the fibres, of a yellowish-grey colour, cross and decussate one another so as to form the same kind of net which is seen in some fibrous zeolites. A variety with detached parallel fibres, which forms small veins of an inch or two in thickness, is mentioned by the same author as occurring in shell lime-stone; its fibres, of a yellowish-brown colour, are very delicate, and separable from one another by the slightest touch. A variety with detached diverging fibres is found at Schemnitz in Hungary.

B. *Stalactitical fibrous lime-stone.* *Kalkfinter*, Wern. *Stalactite* or *Sinter*.

Its more common colours are snow, greyish and yellowish-white, which latter passes into wax and honey yellow, and yellowish-brown; less common are the green varieties of colour, such as siskin, pistachio, asparagus, mountain, and verdigris green, which latter passes into sky blue; sometimes, though rarely, it is flesh, or peach-blossom red, and reddish-brown. When several of these colours occur in the same piece, they are in stripes, sometimes running into each other, at other times perfectly distinct.

It occurs massive, tubular, reniform, globular, botroidal, coralloidal, stalactitic, and tuberoso. Its surface is generally rough, or drusy, with minute indeterminable crystals; internal lustre commonly glimmering, and pearly.

Fracture from very delicately to coarse fibrous; fibres generally straight, stellularly diverging, or parallel. Fragments coniform and splintery, also indeterminately angular. It generally occurs in curved lamellar distinct concretions, parallel to the external surface.

It is more or less translucent, passing into semi-transparent. The remaining characters are those of calcareous spar.

Specif. grav. 2.325—2.876, Brissou; 2.741 (yellowish-
Vol. XXI.

white from Poland), Kirwan. This must of course vary according to the different degrees of purity.

Stalactitical fibrous lime-stone is generally found in caves, crevices, and old shafts, in transition, and flint lime-stone, hanging from and covering the roofs, wall, and floors of the caves, and thus producing groups of figures, which fancy readily transforms into statues, pillars, pulpits, fountains, &c. The most celebrated stalactite caves are, the grotto of Antiparos in Greece, the Bauman's hole on the Harz, the caves of Baden, those of Orenburg and Nerthinsk in Siberia, those of Matlock in Derbyshire, of Yorkshire, Auxelles, d'Arcy, de la Balme in France, &c.

The massive variety of this substance, produced by the trickling down from the roof and walls, and covering the floor of caves, is sometimes distinguished from stalactite by the appellation of *stalagmites*.

Sometimes the conical or cylindrical stalactites are terminated by a small crystal.

The common varieties are used for burning to lime; the finer sorts are employed by the statuary and mason, in countries where they occur in large masses. They are called *marmo alabastrino* by the Italians. See MARBLE.

The beautiful coral-like calcareous substance, called *ferri*, and commonly referred to stalactitical fibrous lime-stone, is a variety of *arragonite*.

4. *Pea-stone.* *Erbsestein*, Werner. *Pierre de pois* or *Pisolite*, Broch.

Its principal colour is yellowish, reddish, and greyish, less frequently snow-white; the yellowish passes through yellowish-grey into cream yellow and yellowish-brown.

It occurs commonly massive, but also reniform and botroidal.

Internally it is dull. Fracture even. Fragments indeterminately angular.

It is composed of spherical distinct concretions, which are again composed of thin concentric lamellæ. These globules are generally connected either by a calcareo-ferruginous cement, or they are detached; their size varies from that of a pea to that of a hazel-nut.

It is opaque, seldom rather translucent on the edges. Soft; brittle; easily frangible.

Specific gravity 2.396, Wiedenmann.

Its chemical characters and constituent parts appear to be those of the preceding sub-species.

The principal locality of pea-stone is Carlsbad in Bohemia. A handsome variety, consisting of detached globules, which are generally composed of fine granular distinct concretions, is found at the baths of St. Philip in Tuscany, and known by the name of *confetto di Tivoli*. Pea-stone is also said to occur in Hungary and Silesia.

Several opinions have been broached to account for the origin of these globular concretions, each of which is furnished with a nucleus of various dimensions, but generally very minute; it is sometimes a small angular or rounded grain of quartz, or a particle of slate; and even small fragments of granite have been seen in the centre of these globules. This circumstance points out the only possible manner in which these concretions can have been produced. The small bodies which serve as nucleus to each globule, must have been raised by, and kept floating in the agitated water of the springs, which being highly impregnated with calcareous particles, gradually deposited round each of them the concentric laminae; the globules thus produced afterwards sunk to the bottom, where, according as circumstances permitted it, they either remained unconnected, or were cemented into solid beds, such as they are seen near the hot springs of Carlsbad.

The similarity which some writers find between the pearl-stone and the variety of compact lime-stone, called roe-stone, is not found in reality.

Lime may be obtained in a state of absolute purity, by several processes from the native substances containing this earth. The analysis of the carbonates of lime is by far the most simple, especially when no other earth or metallic oxyd is present. This is pretty much the case with several of the marbles, particularly the white or statuary marble. If the lime in any of these substances be combined with no other acid but the carbonic, let 100 grains in fine powder be dissolved in muriatic acid. If there be any residuum, it may be considered as flex, or some salt of lime not decomposable by the muriatic acid, and must be set apart. Add to the muriatic solution as much pure ammonia as will make it smell of this alkali, and all the earths, excepting lime, with metallic oxyds, if there be any, will be precipitated, leaving the lime in solution. If no substance be suspected which is soluble in ammonia, the lime may be considered as separated from the other substances, and if such a suspicion should exist, the substance may be separated by adding only just as much ammonia as will make the solution neutral. The lime may be precipitated from the acid with carbonate of potash, or that salt commonly called the sub-carbonat, by which a carbonate of lime is obtained. This white powder, being separated, must be exposed to a strong heat in a platina crucible, to separate the carbonic acid, which leaves the lime in a state of purity. The precipitates by the ammonia may consist of magnesia, iron, and sometimes manganese. The magnesia and manganese will be dissolved by adding a solution of super-carbonat of potash, leaving the oxyd of iron behind, which must be washed and dried. The manganese may be precipitated by the hydro-sulphuret of potash in a state of sulphuret of manganese, which being washed, dried, and exposed to a strong heat in a platina crucible to expel the sulphur, will leave the pure oxyd of manganese. The magnesia, which is yet held in solution by the excess of carbonic acid, may be finally precipitated by pure potash. The precipitate, being separated, may be exposed to a strong heat in a platina crucible, which will give this earth in a state of purity. The resulting substances, on being weighed, will not amount to the original weight of the lime-stone; for, independent of the loss by analysis, allowance must be made for the loss of carbonic acid and water. The total amount of the latter substances may be known, by exposing a given weight in powder in a platina crucible. The loss by weight will be carbonic acid and water. If the carbonic acid alone be required, let a given weight in powder be taken, and let a quantity of dilute sulphuric acid, amply sufficient to saturate all the substances, be accurately weighed; then let the acid and powder be mixed together, and stirred till the effervescence ceases: afterwards weigh the mass; the loss of weight will be carbonic acid. The same may be ascertained by putting the powder into a gas bottle, and adding muriatic acid by degrees from an acid holder, and then collecting the gas in lime-water. The carbonate of lime so collected being weighed, 45 of carbonic acid may be allowed for every 100 of the carbonate.

The example given is supposed to be the most complicated of the carbonates of lime. If flex be a component part, it will be separated in the first solution, and must be washed and dried. Manganese is seldom found in lime-stone. It is said to constitute the property which some lime has of setting under water.

The native sulphat of lime or gypsum may be analysed by the following process. Let a hundred grains of the

crystallized salt, in fine powder, be exposed to a red heat for some time: the loss by this treatment is the water of crystallization. Let the powder, after weighing, be boiled for some time in a solution of pure carbonate of potash, by which is obtained a carbonate of lime, and a sulphat of potash, the latter being soluble, and the former insoluble. To the sulphat of potash, when separated, add muriat of barytes, and the sulphuric acid will be precipitated combined with the barytes. For every 100 of this salt, allow 33.3 of acid, by which the proportion of sulphuric acid will be known.

The insoluble matter first produced will consist of carbonate of lime, and perhaps iron. By adding to this the super-carbonat of potash, the whole of the lime will be dissolved, but the oxyd of iron will be left behind.

The lime which is dissolved by the super-carbonat of potash may be precipitated in the state of carbonate, and made pure by a strong heat in a platina crucible, to drive off the carbonic acid.

Phosphate of lime is analysed by dissolving the native crystals in nitric acid, and adding to the solution acetat, or nitrat of lead, till no more is precipitated: the substance is the phosphat of lead, which being separated and weighed, will determine the quantity of phosphoric acid, by allowing 18.4 of acid for every 100 of the phosphat of lead. The lime which is dissolved in the nitric acid may be precipitated by carbonate of potash.

The flux of lime may be analysed by first boiling it in a state of fine powder with carbonate of potash, or soda, by which a flux of potash or soda is obtained, from which the fluoric acid may be again precipitated by acetat or nitrat of lead, from which the proportion of fluoric acid may be obtained.

The first residuum, which is carbonate of lime, and generally oxyd of iron, must be treated as in the analysis of sulphat of lime, to separate the oxyd of iron from the lime.

The native borat of lime contains more magnesia than lime; for its analysis, see the *Borat of Magnesia*.

Chemical Properties of Lime.—To obtain lime in a pure state, the most perfect crystals of the carbonate should be put into a covered vessel, and exposed to a strong heat, considerably above redness, for several hours. The crystals will retain their shape, but will have lost their transparency, and become beautifully white. By this process the carbonic acid and water of crystallization are expelled, leaving the lime in a state of purity.

The lime thus obtained has a caustic alkaline taste, and like bodies of those qualities, to a certain degree, destroys the texture of the skin, and in other respects acts upon animal substances in general: it also changes vegetable blues to green. Its specific gravity is various; according to Kirwan it is 2.3. In this state it is called quick-lime. Its hardness, immediately after it is produced from the carbonate, is not much diminished; but if exposed to the air for a certain time, it falls into an impalpable powder, which appears of a more splendid white than in the solid state.

In assuming this form by exposure, it is found to be heavier by one-third of its original weight. For this fact we are indebted to Mr. Dalton, who terms lime in this state an *hydrat of lime*.

If it be exposed to the air a longer time, it combines with carbonic acid, and would ultimately acquire the original weight of the carbonate.

When water is poured upon newly burned lime, it quickly swells with a hissing noise, absorbing the water with great avidity, while much heat and even light are evolved.

These

These phenomena do not cease till it has absorbed one-third of its weight: in this state it is called *slacked lime*.

Many other substances are capable of furnishing lime in a state of tolerable purity. Of these are the stalactite of Derbyshire, chalk, white marble, and some of the other marbles.

Lime is not fused by the greatest heats hitherto produced, although it is susceptible of fusion by very slight admixture of some earths and metallic oxyds.

The change which takes place in all these bodies which afford lime by burning, was not explained before the discovery of carbonic acid by Dr. Black. The peculiar qualities of quick-lime were supposed by Boyle and by Newton to arise from the fire fixed in it by the process of burning. Others supposed its causticity to arise from the presence of an acid formed by the heat. Dr. Black, however, demonstrated that the qualities of lime were not to be attributed to the presence of any substance in lime, but to the absence of water and carbonic acid, the latter of which he at the same time discovered.

If lime be added to water at 60°, it dissolves about .005 of its weight. It appears from the experiments of Dalton, that cold water dissolves more lime than hot; a property not common to other bodies. According to this ingenious chemist, water at 60° dissolves $\frac{1}{13}$ of its weight; at 130, $\frac{1}{24}$ part; and at 212°, $\frac{1}{137}$ part.

The solution of lime in water is commonly called *lime-water*. When lime-water is exposed to the air, it soon becomes covered with a pellicle, exhibiting the prismatic colours, which gradually thickens into a crust, and by its weight falls to the bottom of the liquid. This has been called the cream of lime. It is produced by the lime combining with the carbonic acid of the atmosphere, by which it becomes insoluble, and is separated from the water.

The same separation takes place by breathing through lime-water, from the presence of the carbonic acid afforded by respiration.

Lime combines with several of the combustible bodies, forming peculiar compounds. When two parts of lime and one of sulphur are heated together in a crucible, they unite in forming a reddish mass, which is the sulphuret of lime. When this compound is moistened with water, the latter is decomposed. One portion of the hydrogen of the water unites with a portion of sulphur, and escapes under the form of sulphuretted hydrogen gas. Another portion combines with a part of sulphur and lime, forming a triple compound of sulphur, hydrogen, and lime, called an hydroguretted sulphuret of the earth, while the oxygen of the decomposed water, with the remainder of the sulphur and lime, forms the sulphat of lime.

The hydroguretted sulphuret of lime is of a greenish-yellow colour. If exposed to the air for some time, it gradually absorbs oxygen, and is converted into sulphat of lime. If, however, it be kept in solution in water in a close vessel, some of the sulphur gradually precipitates, leaving in solution the hydrosulphuret of lime. See *Sulphuretted Hydrogen*.

The hydroguretted sulphuret of lime has the property of dissolving charcoal as well as some metals, and metallic oxyds.

The hydrosulphuret of lime is formed by passing sulphuretted hydrogen gas through lime-water. This gas unites with the lime, forming a compound of a disagreeable bitter taste.

Phosphuret of Lime.—This substance may be formed as follows: into an earthen tube about 12 inches long, or a glass tube coated with equal parts of sand and pipe-clay,

and closed at one end, put some pieces of phosphorus, so as to lie at the closed end of the tube. Let the remainder of the tube be filled with bits of newly burned quick-lime, about the size of large peas, and then stop the end of the tube with a chalk or dry clay stopper, not fitting very tight. Let the tube be now passed through two holes of a portable furnace, the furnace being about six inches in diameter. One of the holes must be a little below the other, so as to give the tube a small inclination to the horizon, the open end being highest. Let the middle part of the tube be heated red-hot, and then draw gradually the end containing the phosphorus into a heat sufficient to sublime the phosphorus. The vapour of the latter will now pass through the red-hot lime, a great portion of which will combine with it, forming the phosphuret of lime. If the vapour of the phosphorus come too rapidly it passes by the loose stopper, but so soon as the whole has been sublimed, let the end be stopped more closely; and let the tube be withdrawn, keeping it well stopped till it is perfectly cold. The whole of the contents of the tube may now be shaken out, and the darkest coloured pieces selected, which must be kept in a well stoppered dry bottle.

The phosphuret of lime, thus prepared, is of a deep brown colour.

When thrown into water it does not dissolve, but bubbles of gas are seen to proceed from it, which coming to the surface burst, and inflame spontaneously, producing a beautiful ring of white smoke.

These phenomena are occasioned by the presence of a substance called phosphuretted hydrogen gas, which has the singular property of taking fire at the common temperature. The water is decomposed by the phosphuret. The hydrogen combines with a portion of the phosphorus, forming the gas above-mentioned, while the oxygen of the same combines with the remainder of the phosphorus, forming phosphoric acid, which with the lime forms phosphat of lime. Besides this, a portion of the gas first combines with the phosphuret, forming an hydroguretted phosphuret, which, if taken from the water before it is decomposed, and wiped dry, retains the gas. On pouring muriatic acid upon it the gas is liberated, and instantly inflames.

Lime does not combine with any other of the inflammable bodies, but it combines with several of the metallic oxyds.

When any of the oxyds of lead are boiled with lime and water, a portion of the oxyd is dissolved. The solution, on evaporation, affords small crystals.

This compound has the property of staining wool, hair, nails, horn, and some other animal substances, of a deep and agreeable brown, which by exposure to the air disappears. This colour appears to be the brown oxyd of lead combined with the substance. An acid instantly dissolves it, and the colour disappears.

Lime also dissolves the red oxyd of mercury, of the solution affording yellow crystals.

Lime has the property of combining with some of the other earths and metallic oxyds, forming mortars of different qualities. Dr. Higgins, in his book upon cements, proposed the following as the best composition for common mortar: three parts of fine washed sand, four parts of coarser sand, one part of newly slacked lime made up with as little water as possible, which he recommends to be moist water. Mortar, thus formed, becomes very hard in a little time, and continues to become harder for a great length of time. Hence has arisen the mistake, of the ancients being in some secret of making mortar, which is not known to the moderns.

A great improvement has lately been made in making

cements by combining lime with oxyd of iron and manganese. An iron ore abounding with clay, a calcareous matter, and pyrites, have been introduced under the name of "Parker's cement," from the name of the inventor and patentee. After burning and grinding to powder, it has the property of setting rapidly when mixed with water, and even under water. This rapid induration can be explained, only by supposing a great affinity to exist between the different earths and metallic oxyds in its composition.

Lime had long been suspected to be a compound body; but it is only lately that this fact has been verified by experiment. From the general resemblance of the earths to the oxyds of many of the metals, Lavoisier supposed them to be oxyds of metals, which had to great an affinity for oxygen as not to be reduced by ordinary means. Several unsuccessful attempts were made to realize this conjecture by different philosophers.

In the late experiments of Mr. Davy, in which he discovered the fixed alkalies to consist of metallic bases united to oxygen, this philosopher was led to suppose that the earths, at least those having alkaline qualities, might be compounds of peculiar bases united to oxygen; and in this conjecture he seems not to have been misled.

Mr. Davy did not succeed in obtaining the metalloid of lime in a pure state, as in the instances of potash and soda. He fused a portion of lime and potash together, and exposed this compound to the action of the Galvanic battery, in the same way he had done potash and soda. He obtained by this means a metallic substance, which differed from the metal of potash in being less fusible, and took fire as soon as it was formed. He succeeded better by moistening the lime, and mixing it with red oxyd of mercury. These were placed upon a plate of platina, connected with the positive end of the battery. A cavity being made in the mixed mass, a globule of mercury, weighing about 60 grains, was placed in it, and a connection formed between the mercury and the other end of the battery by means of a platina wire. By this means, the lime underwent decomposition; its metallic base combining with the mercury. This amalgam was then distilled in a glass tube, filled with the vapour of naphtha; by which the mercury, to a certain extent, was expelled, leaving a white mass of a metallic appearance, and of the colour of silver. This substance, which no doubt was the basis of lime, had so great an attraction for oxygen, that Mr. Davy could not succeed in examining its properties before it was burned and reconverted into lime. He has given it the name of *Calium*.

Salts of Lime.—Lime combines with the different acids, forming peculiar compounds called salts.

It possesses a stronger attraction for the acids than alumina, magnesia, or any of the metallic oxyds: hence the existence of aluminous, magnesian, and metallic salts are incompatible with lime. Several of the salts of lime are found native in great abundance, particularly the carbonate and sulphate. We rarely find a mineral water free from some of the salts of lime. They are mostly, however, the carbonate, sulphate, and muriate; the rest of the native salts being insoluble in water.

Sulphate of Lime.—This salt may be formed by dissolving lime in the maritine or nitric acid, and adding sulphuric acid to the clear solution, till the precipitation ceases. The substance which falls to the bottom is the sulphate of lime, in a state of white powder. It abounds so plentifully in nature, that it is never manufactured for sale. The native crystals are right-angled prisms, with rhomboidal bases. It is also found sometimes in crystals of the form of four

and six-sided prisms, which are generally very transparent. In some specimens these crystals are very small, giving the mass a fibrous appearance. It occurs in Derbyshire, in large semitransparent masses, mostly abounding with yellowish-brown streaks, occasioned by the presence of iron. Great quantities of this salt is worked into ornaments, and used also in sculpture.

This salt is soluble in 460 parts of water at 60°.

It is not altered by exposure to the air, at the common temperature: if, however, it be heated to ignition, it loses its water of crystallization, and falls into a fine white powder. This powder, if left in the air, would re-absorb the water, and assume its chemical qualities. When this powder, newly calcined, is mixed with water to the consistence of pulp, it soon begins to stiffen, becomes warm, and in a little time becomes very hard. During this state it expands with great force, so as to break very strong vessels. It admits of the most delicate casts being taken by means of it. The sudden expansion, at the time it is losing its liquid form, forces it into the most minute cavities. It is employed by artists for making casts of busts, and different ornaments. The same properties render it of great value to the manufacturers of pottery and porcelain. It is used in some countries for making the floors of upper rooms, as a substitute for wood. In the laying of these floors, some idea may be given of its expansive force when setting. Thin slips of wood, of a thickness equal to the expansion of the floor, are placed between the wall and the pulpy mass, till the time it begins to assume the solid form. These slips are then instantly removed, to make room for the expansion. If this precaution were not taken, so great would be the force, as to push out the wall in that part.

Sulphate of lime is composed, according to Bergman, of 46 acid, 52 base, and 22 water, in the 100. Kirwan's analysis gives 59 acid and 41 base in the 100. Wenzel makes it 59.84 acid and 40.16 base.

Dalton makes the atom of lime 24, and sulphuric acid

$13 + 3 \times 7 = 34$: hence, $\frac{24 + 34}{34} = \frac{100}{58.6}$, which gives 58.6 acid, and 41.4 base, = 100.

This salt is said to be used in America as a manure with much success; but has not been used in this country.

Sulphite of Lime.—This salt may be formed by adding sulphurous acid to the nitrate or muriate of lime. A white powder is precipitated, which is sulphite of lime. This salt is soluble in 100 parts of water. It is slightly efflorescent in the air, and ultimately is converted into sulphate. When heated, some sulphur is sublimed, and it assumes the state of sulphate. This salt is composed of 48 acid, 47 lime, and 5 water, = 100. It has not been applied to any use.

Nitrate of Lime.—The nitrate of lime may be formed by adding powdered carbonate of lime to nitric acid, till the effervescence ceases. When the solution is evaporated to the consistence of syrup, and placed in a very cold situation, small needle-shaped crystals, after some time, will appear: the shape of these is six-sided prisms. This salt is crystallizable, but with difficulty, owing to its great solubility; or, in other words, to its great affinity for water; and when the crystals are formed, they soon attract moisture from the air, and disappear.

When the solution is evaporated to dryness, and the heat continued a short time, the mass acquires the property of glowing in the dark. This salt is known by the name of Baldwin's phosphorus.

When a stronger heat is applied, up to ignition, the salt is decomposed; the acid is resolved into nitrous gas, oxygen,

gen, and nitrogen. It might be employed, like nitre, to obtain a tolerably pure oxygen for experiments of combustion. Its decomposition by heat also furnishes an elegant method of procuring lime in a state of purity. The analysis of this salt by Richter gives, in the 100, 63.9 acid, and 36.1 base. That of Kirwan gives, in the 100, 54.44 acid, 32 base, and 10.56 water. Dalton makes the atom of nitric acid $5.4 + 2 \times 7 = 19.4$, and concludes the soluble

nitrats to be super-salts: hence, $\frac{10.4 \times 2 + 24}{19.4 \times 2} = \frac{100}{58.6}$,

which gives 78.6 acid, and 41.4 of lime, = 100.

Muriat of Lime.—This salt is generally formed in manufacturing the carbonat of ammonia. The muriat of ammonia is mixed with carbonat of lime, in a vessel which is exposed to a heat capable of fubliming the carbonat of ammonia, which leaves behind the muriat of lime. It may be also formed by adding carbonat of lime to muriatic acid. When the solution is evaporated to the consistence of syrup, and set in a cool place equal to 32° , it crystallizes into fixed prisms, terminated by pyramids. These crystals, however, soon deliquesce, from their great attraction for moisture, and assume the liquid form. Reduced to a state of dryness, it is used for the purpose of drying different gases.

Water at 60° dissolves four times its weight of this salt; while at 100° , it dissolves in any proportion. It dissolves in alcohol in a great proportion, producing heat. When the dry salt is mixed with snow, it produces great cold, and is employed to great advantage in freezing mixtures. When it is exposed to heat above ignition, some of the acid escapes, reducing it to the state of submuriat. In this state it has the property of shining in the dark, and has, in consequence, been called the phosphorus of Homberg. It is composed, according to the analysis of Bergman, of 31 acid, 44 base, and 25 water, in 100. Kirwan makes it 42 acid, 50 base, and 8 water; and Wenzel, 51 acid and 49 base. Dalton makes an atom of muriatic acid 22; then lime being

24, $\frac{24 + 22}{22} = \frac{100}{47.83}$: hence we have, from these data,

47.83 of acid, 52.17 of base.

Oxymuriat of Lime.—It appears that such a salt does not exist, except in the dry state. When it is thrown into water, it is converted into the muriat, and oxygen escapes.

The salt, which the bleachers call the oxymuriat of lime, is in fact the hyper-oxymuriat. It is made by passing the oxymuriatic acid gas through a mixture of lime and water, in a Woulfe's apparatus. (See LABORATORY.) The lime is at length taken up, and the liquid becomes colourless. It is decomposed by the muriatic acid, affording oxygen and oxymuriatic acid. It is used in bleaching to a great extent. See BLEACHING.

Phosphat of Lime.—This salt constitutes the basis of bones, and is a component part of most animal substances. It may be prepared by adding muriat or nitrat of lime to phosphat of soda; or, cheaper, by dissolving the earth of bones, which is a mixture of the subphosphat and carbonat of lime, in muriatic acid, and adding pure ammonia to the solution. The phosphat of lime will be precipitated alone, leaving the excess of lime dissolved in the acid. This salt is in the form of powder of a white colour; the native salt, which has been described, being alone capable of the crystalline form.

Several of the acids, but particularly the sulphuric, decompose this salt, by taking a part of the lime, and leaving it in the state of superphosphat. Phosphat of lime is com-

posed, according to the analysis of Klaproth, of 32.5 of acid and 69.5 base. Fourcroy and Vauquelin make it 41 acid and 59 base; Richter, 45 acid and 55 base; and Ekeberg, 39 acid, 36 base, and 25 water. By Dalton's hypothesis, the phosphoric acid is $9 + 2 \times 7 = 23$: then, $\frac{23 + 24}{23} = \frac{100}{48.9}$, making the acid, in 100, 48.9 acid, the base being 51.1.

Superphosphat of Lime.—When sulphuric acid is added to the phosphat of lime, the former being one-third of the latter by weight, a portion of fulphat of lime will be formed, which will be precipitated, leaving the superphosphat dissolved. It may also be formed by dissolving 47 parts of the phosphat in 23 parts of real acid.

This salt crystallizes by evaporation, in brilliant plates, having a pearly appearance. The taste of these crystals is strongly acid. Indeed it was once taken for the phosphoric acid, and was distilled with charcoal, to obtain phosphorus. This salt is now decomposed by the acetat of lead; and the phosphat of lead is used for that purpose, which is found a great improvement in the preparation of phosphorus.

When this salt is heated in a crucible at a little more than a red heat, it fuses; and, on cooling, assumes the appearance of a transparent glass, which has been called phosphoric glass. Its composition, according to the analyses of Fourcroy and Vauquelin, is 54 acid and 46 lime.

Fluat of Lime.—This salt is not a product of art, but is found native in Derbyshire, and other counties abounding with lead. Its crystals are in the form of cubes.

When this salt is coarsely powdered, and laid upon a hot plate, a little short of ignition, it gives a beautiful blueish light, not much unlike the flame of burning sulphur in common air. The artificial fluat also possesses this property.

When the fluat of lime is exposed to a strong heat, it melts, and, on cooling, becomes transparent. The facility with which it fuses, and renders other earthy substances fusible, is taken advantage of in the reduction of lead, and other metals. Hence it has derived its name from acting as a flux.

This salt is decomposed by the nitric and sulphuric acid, by seizing the lime, while the fluoric acid gas is disengaged. Guy Lussac and Thenard have lately shewn, that the gaseous form of its acid is caused by the presence of silic; since, when it is disengaged from any base where silic is not present, the acid assumes the liquid form. See SILEX.

Its analysis, by Klaproth, is 32.25 acid and 67.75 base; by Dr. Thomson, 32; acid and 67½ lime.

Borat of Lime.—This salt may be formed by mixing the muriat of lime with a solution of borat of soda. The salt is precipitated in the state of white powder, which is insoluble in water: few of its properties are known.

Carbonat of Lime.—This salt, in the native state, is the most abundant of all the calcareous salts.

Although the primitive forms of the crystals of it are rhomboidal prisms, this figure has been to differently arranged as to form a numerous variety of secondary forms. The neutral salt of this species is insoluble in water; but it becomes soluble, to a certain degree, with an extra dose of acid.

The carbonat of lime may be formed by adding carbonat of potash to muriat of lime. It consists of 45 acid and 55 lime.

According to the experiments of sir James Hall, when the carbonat of lime is exposed to a red heat, in a close vessel, such as a gun barrel, it melts; and, on cooling, is found

found to retain its original properties, with the exception of losing something less than 4 or 5 per cent. of carbonic acid.

Supercarbonat of Lime.—When the supercarbonat of potash is added to muriat of lime, a portion of lime will remain on solution, which is not the carbonat of lime, but a supercarbonat. This salt is very frequently found in mineral waters, especially in lime-stone countries, and in countries abounding with marble.

A carbonat of potash being added to a solution of this salt, takes one dose of acid from it to form a supercarbonat, and the carbonat of lime is thrown down. When the supercarbonat of potash is added, no change takes place. When lime-water is added to water dissolving the supercarbonat of lime, the lime of both assumes the state of carbonat, and fall down together.

When the supercarbonat of lime is exposed to a boiling heat for some time, the second dose of acid is expelled, and the remaining carbonat is precipitated. This salt, however, is not immediately decomposed by boiling, but requires to boil for some time.

Acetat of Lime.—If carbonat of lime be added to the acetic acid, an effervescence will take place, and the lime will be dissolved in the acetic acid, forming acetat of lime. If the solution be evaporated, it affords small crystals of a white colour, having a silk appearance.

It has a bitter acid taste.

It is composed of 65.11 acid and 34.89 lime.

Oxalat of Lime.—This salt is formed by dropping the oxalat of ammonia into any solution of lime. It appears to be the most insoluble of all the salts of lime. It is in the form of white powder, and is composed, according to Bergman, of 48 acid, 46 lime, and 6 water.

Tartrat of Lime.—If carbonat of lime be added to a solution of the supertartrat of potash, the excess of tartaric acid combines with the lime, which falls in the state of insoluble powder. It is from this insoluble tartrat that the tartaric is obtained, by means of sulphuric acid.

Citrat of Lime.—This salt, like the last, is formed by adding the carbonat of lime to citric acid in the lemon juice. The salt is the insoluble powder which falls to the bottom. It is from this salt that the citric acid is obtained pure, by the superior affinity of sulphuric acid.

It consists of 62.66 acid and 37.34 lime.

Prussiat of Lime.—The prussiat of lime is formed by dissolving lime in the prussic acid. It is decomposed by all the acids, and is of little permanence. The salt commonly, but improperly, called by this name, is a triple salt, containing both lime and iron. It is made by adding 56 parts of lime water to two parts of Prussian blue, well washed in hot water, boiling them for some time till the lime is saturated. The solution is of an olive colour, and affords crystals by evaporation. The solution of this salt is a valuable test for iron in mineral waters.

The rest of the salts of lime are not of any importance, as far as we at present know.

The arseniats and molybdat of lime are insoluble in their neutral state: the former is soluble in excess of acid.

Succinat of Lime is difficultly soluble.

Benzolat of Lime is soluble, and may be obtained in crystals.

Chromat of Lime is soluble and crystallizable.

Suberat of Lime dissolves in hot, but little in cold water.

Camphorat of Lime is sparingly soluble.

LIME, in Agriculture, a soft friable substance, obtained

by calcining or burning various calcareous materials, such as chalk, marble, lime-stone, shells, &c.

This is a substance which is in different states, according to the particular circumstances under which it exists. When newly made, from its great power of destroying the texture of bodies, it is termed caustic or quick lime. It is also sometimes called shell-lime or shells. In this state, when used as manure, it operates with the greatest violence, dissipating and robbing the soils, to which it is applied, of their moisture and other fluid matter: but after being exposed to the atmosphere for some time, from its property of quickly absorbing moisture and carbonic acid from it, it becomes mild or effete, and is termed carbonat of lime. When applied to land in this state, it acts with much more mildness, only promoting the resolution of the matters in which it comes in contact, by forwarding the natural process of putrefaction. It has also less tendency to produce a mortary hardness in the poorer sorts of clayey soils. But besides these differences, there are others arising from the substances which are combined with the calcareous matters employed, as has been lately shewn by the ingenious experiments of Mr. Tennant, stated in the second part of the Philosophical Transactions for the year 1799. Having been informed that two kinds of lime were used in agriculture, which differed greatly in their effects,—one of which it was necessary to use sparingly, and to spread very evenly over the land, as it was said that a large proportion of it diminished the fertility of the soil, and that, wherever a heap of it had been left on one spot, all vegetation was prevented for many years; and that of this kind of lime, 50 or 60 bushels on an acre were as much as could be used with advantage; while of the other sort of lime, a large quantity was never found to be injurious, and that the spots which were entirely covered with it became remarkably fertile, instead of being rendered barren:—having analysed those two kinds of lime, he found that the latter consisted solely of calcareous earth; but that the former contained two parts of magnesia, with three parts of calcareous earth. He afterwards proved, that though vegetable seeds would grow equally well in both these kinds of lime-stone, when simply reduced to powder; yet that, when they were calcined so as to become lime, and both of them strewed about the tenth of an inch thick on garden mould, the magnesian lime prevented nearly all the seeds which had been sowed from coming up, while no injury was occasioned by the calcareous lime, when used under the same circumstances.

It may be noticed, that this valuable discovery seems in some measure to explain the cause of the variety of opinion that has been maintained respecting the application of lime, which some have supposed to be of little or no advantage, and even injurious to land; which has been owing probably to their having employed the magnesian lime, or used it in too large proportions.

This philosophical inquirer first found magnesian lime near the town of Doncaster, and afterwards at York, at Matlock in Derbyshire, at Breeden in Leicestershire, and at Worklop in Nottinghamshire. He asserts, that the cathedral and walls of York are built with this magnesian lime-stone; and that at Matlock the magnesian and calcareous lime-stones are contiguous to each other, the rocks on the side of the river Derwent, where the houses are built, being magnesian, and on the other side calcareous. He found also, that in this situation the magnesian lime-stone was incumbent on the calcareous: for, in descending into a cavern formed in that rock, he found a separate vein of calcareous lime-stone, which was full of shells, but contained no magnesia.

nesia: and concludes, that, in general, the magnesian lime-stone may be easily distinguished from the calcareous, by its solution in acids being much slower, and that it contains generally very few shells; but that these, when present, are impregnated with magnesia.

In the Philosophy of Agriculture it is remarked also, that all lime-stone may be divided into three kinds: first, the rocks which remain, where they were formed from shells beneath the ocean, except that they were afterwards elevated by sub-marine fires: secondly, into alluvial lime-stone, as those which have been dissolved in water, and simply precipitated, as the beds of chalk, which contain only the most insoluble remains of sea animals, as the teeth of sharks; and, thirdly, those which, after having been dissolved and precipitated, have been long agitated beneath the sea, till the particles have been rolled so against each other, as to acquire a globular form, which is said to resemble the roe or spawn of fish, and which contain very few shells, or none, as the Ketton stone, and that which he has seen on Lincoln heath, extending almost from Sleaford to Lincoln. Now, says he, as the salts of the sea consist of only two kinds; common salt, or muriat of soda, and vitriolated magnesia, commonly called Epsom salt, which, in the sea-waters surrounding this island, are found at a medium to exist in the proportion of one-thirtieth part of common salt and one-eightieth part of vitriolated magnesia, compared to the quantity of water; and, secondly, as these salts are believed by many philosophers to have been formed by vegetable and animal matters, which principally grew upon the surface of the dry land, after it was raised out of the primeval ocean; and that, in consequence, the saltiness of the sea was posterior to the formation of the primeval rocks of lime-stone; we may understand why those lime-stone strata, which have not been dissolved or washed in sea-water since the sea became salt, are not mixed with magnesia. The chalk, he supposes, must have been dissolved and precipitated from water, as it exactly resembles the internal part of some calcareous stalactites which he has in his possession; yet there is no appearance of its component particles having been rubbed together into small globules, and may not, therefore, have been removed from the situation where it was produced, except by its elevation above the surface of the ocean. But that alluvial lime-stone, which consists of small globules adhering together, called Ketton lime-stone, and of which there appears to be a bed 10 miles broad from Beekingham to Sleaford in Lincolnshire, and 20 miles long from Sleaford to Lincoln, he suspects may probably consist of magnesian lime-stone; which is also said in that country to do no service to vegetation: for this alluvial lime-stone, by having evidently been rolled together beneath the sea, by which the small crystallized parts of it have had their angles rubbed off, is most likely to have thus been mixed with the magnesia of the sea-water, which, as has been observed, is said to contain one-eightieth part of its weight of vitriolated magnesia.

It is further remarked, that at the lime-works at Ticknal, near Derby, there appears a stratum of alluvial lime-stone, like Ketton lime-stone, which they do not burn for sale, over the bed of the calcareous lime-stone, which they get from beneath the former, and calcine for sale. It is probable, he thinks, that the superior bed may contain magnesia, which has rendered it not so useful in agriculture. It is still more probable that alluvial lime-stone has acquired its mixture of magnesia from the sea-water; as magnesia, in its uncalcined state, will precipitate lime from water, as observed by Dr. Alison, who thence proposes to render water pure and potable, which has been long kept at sea free from

putridity by having lime mixed with it, by precipitating the lime by the addition of mild magnesia.

The lime from Breedon is magnesian, that from Ticknal (which is sold) is calcareous, he believes; and some farmers in the vicinity of Derby assert, that two loads of Breedon lime will go as far, that is, will apparently do as much service to their land, as three loads of Ticknal lime. Breedon lime, he is also informed, is preferred in architecture, and is said to go further in making mortar; which, he supposes, means that it requires more sand to be mixed with it. In the Account of the Agriculture of the Midland Counties, lime made at Breedon, near Derby, is said to be destructive to vegetables, when used in large quantities; and in Nottinghamshire it is asserted, that the lime from Critch, in Derbyshire, is so mild, that thistles and grafs spring up through the edges of large heaps of it, when laid in the fields. Dr. Fenwick of Newcastle observes, that the farmers in that country divide lime into hot and mild; which Mr. Tennant believes to mean magnesian and calcareous lime.

By experiments which were made by Mr Tennant, by sowing seeds of colewort on various mixtures of calcined magnesia with soil, and of calcareous lime with soil, he found thirty or forty grains of lime did not retard the growth of seeds more than three or four of calcined magnesia: hence, what can we conclude, but that, as they both injure vegetation in large quantities, they may both assist vegetation in small ones? and that this is more probable, as the farmers believe that they find both of them useful, though in different quantities; and as the magnesia would form Epsom salt, if it met with vitriolic acid, which Dr. Home found, from his experiments, to be friendly to vegetation, when used in very small quantities. More accurate observations and experiments are, however, Dr. Darwin thinks, wanting on this subject.

The most certain way to know whether any sort of stone be fit for making lime is to drop upon it a little aquafortis, spirit of sea-salt, or oil of vitriol. All stones on which the above, or any other strong acid, effervesces or rises in bubbles, are calcareous stones, or will burn to lime; and the stronger the effervescence is, the fitter they are for that purpose.

And as in the use of calcareous matter as a manure, much depends upon its being brought into a fine powdery state, it should always, where fuel can be obtained at a moderate expence, be prepared by burning, as that is the easiest and most efficacious mode of reducing lime-stone to powder that ever was invented, and therefore ought always to be adopted where necessity does not prevent it. Reducing lime-stone to powder by calcination is also, he remarks, attended with this farther advantage to the farmer, that it considerably diminishes his expence of carriage. Pure lime-stone loses about two-thirds of its weight by being thoroughly burned; so that the man who is obliged to drive this manure from a great distance, will find a very considerable saving by driving it in the state of shells; but if it were reduced to a powder by mechanical triture, he could not be benefited by this circumstance. Many persons choose to drive lime-stone from a considerable distance and burn it at home; but it is obvious they then subject themselves to a very heavy charge in carriage, which would be avoided by an opposite conduct. This, therefore, ought never to be practised but where other circumstances may counterbalance this unfavourable one. But as lime-stone is often in its native state mixed with sand in various proportions, and as sand loses nothing of its weight by calcination, it must happen that those kinds of lime-stone which contain the largest proportion of sand will lose least in calcination, and of course afford the weightiest lime-shells.

Hence

Hence it is obvious, that those who are under the necessity of driving lime from a great distance ought to be particularly careful to make choice of a kind of lime-stone as free from sand as possible, and to drive it in the state of shells, as they will thus obtain an equal quantity of manure at the least expence of carriage that is possible; and the lightest shells ought, of course, to be always preferred. When lime is flaked, that which contains most sand falls most quickly, and absorbs the smallest proportion of water. What is pure requires a very large proportion of water, and is much longer before it begins to fall. Hence it happens that those who drive sandy lime-shells in open carriages, must be very careful to guard against rain, because a heavy shower would make the whole fall, and generate such a heat as to be in danger of setting the carts on fire; whereas pure lime-shells are in no danger of being damaged by that circumstance. The writer has seen a cart loaded with such shells, which had been exposed to a continued shower of rain, as violent as is ever known in this country, for more than three hours, and seemed hardly to be affected by it in the smallest degree. He ought, he says, to observe, however, that his experiments were confined to only one kind of pure lime, so that it is not from hence demonstrated that all kinds of pure lime will be possessed of the same qualities. Lime-shells formed from the purest lime-stone require more than their own weight of water to flake them properly; whereas, some kinds of lime-shells that contain much sand do not require above one-fourth part of that quantity. He has found, by experiment, that pure lime-shells cannot be flaked with less than about one-fourth more than their own weight of water. When flaked in the ordinary way, the same lime-shells took more than double their weight of water.

Hence it is much worse economy, in those who have pure lime-shells, to flake and carry them home in the state of powdered lime, than it is in those who have only a sandy kind of lime-shells to make use of.

It is farther suggested that it is even, on some occasions, more advisable for those who have very sandy lime, to drive it in the state of powdered lime than in that of shells; for, as it is dangerous to give that kind of lime-stone too much heat, lest it should be vitrified, those who burn it can never be certain that the whole of the stone will fall to powder when water is added, till they have actually tried it; nor do they think it a great loss if some part of it should be imperfectly burned, as it requires much less fuel on a future occasion than fresh lime-stone; and therefore they much rather choose to err on this than on the opposite extreme. But should any one attempt to drive this poor sort of lime in the state of shells, he would be in danger of carrying home many stones that would never fall; which would more than counterbalance the benefit he would derive from the want of the small quantity of water that is required to flake it. On these accounts it is supposed it may be admitted as a general rule, that those who can have access to lime-stone which is free of sand, will save a great deal in the carriage of it by driving it in the state of shells; and that, on the contrary, it will be most economical, to those who can only get lime of a very sandy quality, to drive it in the state of powdered lime. Hence it follows, that the practice which now prevails, of carrying shell-lime by water from one part of the country to another, is only an imaginary saving, obtained at a very high risk, to those who drive shells of a sandy quality; but a real and unequivocal advantage of very high importance to the community at large, if these shells are obtained from a pure lime-stone. These observations relate only to the saving of carriage to the farmer; which, however, is an article of great importance to him.

But there are some other particulars that may also equally affect him in this way, and in the application of the lime to his ground. A vague opinion in general prevails in every part of the country, that one sort of lime may be more valuable than another; but it does not appear that farmers have hitherto had any rule to direct them in the choice of different sorts of lime; some esteeming one sort strongest, as they term it, and some valuing another sort more highly, without being able to assign any satisfactory reason for the preference they give in either case. It is of importance that this matter should be elucidated. Although it does not always happen, yet, in many parts of the country, the real nature of lime is so little understood, that the weightiest lime is preferred as a manure to that which is lighter; because it is imagined the first has more substance, and will therefore produce a more powerful effect upon ground than the finest and lightest lime. But there seems to be no reason to think there is any difference in the specific gravity of different parcels of pure calcareous matter when fully calcined; therefore, if there is any difference in the weight of various sorts of lime, it must arise entirely from a variation in the quantity or gravity of some extraneous matter that is mixed with the lime; and as sand is almost the only extraneous body that is ever found in lime-stone, and is always of much greater specific gravity than pure quick-lime, it follows, that the weighty lime only owes its superior gravity to a larger proportion of sand that is mixed with it. But sand is of no value as a manure; so that he who voluntarily purchases this kind of lime in preference to the other is guilty of a great degree of folly; which will be the greater if he has likewise to drive it from a considerable distance.

However, those farmers who have access to only one sort of lime-stone, must be contented with it, whatever may be its quality. But such as have an opportunity of choosing may be benefited by the observation, that pure lime-stone, when fully calcined and flaked, is reduced to a fine white impalpable powder that feels soft between the fingers, without the smallest tendency to grittyiness; while such lime as contains sand is never so fine nor so soft, but feels gritty when rubbed between the fingers. See Anderson's Essays.

Action, Quantity, and Application of Lime.—The author of Modern Agriculture remarks, that there are few districts where lime is not either in general use, or partially introduced as a manure. With respect to the use of lime, or the benefit derived from it as a mean of fertilizing the soil, some are of opinion that it promotes vegetation, by stimulating, or forcing the soil with which it is incorporated to exert itself: others imagine it promotes vegetation by enriching the soil, and thereby adding to the quantity of vegetable food. Various other opinions, different from these, and in some instances opposite to each other, have been entertained respecting the manner in which lime operates upon land; but all that we yet know with certainty on the subject, is collected from practice and experience, whereby it is proved that lime somehow or other operates so as frequently to produce exuberant crops on soils which, before the application of that manure, were comparatively of little value; and farther, that on all soils which are treated properly after being thoroughly limed, its beneficial effects are discernible by the most cursory observer. Various other modes in which this substance may be useful as a manure, may be seen under the terms *Calcareous Earth*, and *Phosphorus*.

The proportion or quantity of lime applied to the acre seems hitherto, the same writer observes, fixed by no certain rule, either in regard to the nature of the different soils, the modes

modes of cropping afterwards adopted, or the superior quality of one kind of lime-stone beyond another.

It has been remarked, that some require that it should be applied in such small quantities as thirty or forty bushels to the acre; and aver, that if more is used the ground will be absolutely ruined; while others maintain, that ten times that quantity may be applied with safety. A great variation may no doubt be produced, in this respect, by a difference in the nature of the soil, in the state of culture it is under at the time, in the quantity of calcareous matter with which it may have been formerly impregnated; and perhaps a variation may sometimes arise from other circumstances that have never yet been attended to. A difference will likewise arise from the quality of the lime that is applied, and from the manner in which it is employed, some kinds of lime containing, perhaps, ten times more calcareous matter than others: and a very great difference may proceed from the mode of applying the lime itself. For it is common to hear those who have had little experience of lime as a manure, recommend very great caution, lest too great a quantity be employed, for fear of burning the soil, as they express it. This idea of burning has been evidently adopted from what is experienced by applying caustic lime to animals or vegetables in large quantities, as it often corrodes and shrivels them up, and produces other effects, which greatly resemble those of fire; but it cannot produce any such effects, unless there are vegetables growing upon the soil at the time. In that case the vegetables might indeed be corroded by the lime, if rain should fall immediately after it was spread when newly slaked; but as it loses this fiery corrosive power in a few days after it is spread, nothing of that kind can be expected to happen to the soil. Accordingly, we never hear of crops being burnt up with too great a quantity of lime in those counties where it has long been used as a common manure, although it is there often employed in much larger quantities than in other places where it is more rare. The writer has himself had the experience of lime in all proportions, from one hundred to above seven hundred bushels to the acre, upon a great variety of soils; and has always found that its effect in promoting the fertility of the soil has been in proportion to the quantity employed, other circumstances being alike. The expence, in most cases, prevents farmers from employing this manure in greater quantities than those above-mentioned; but accidental circumstances clearly shew, that if it were applied in much larger quantities, the effect would only be to promote the luxuriance of the crop in a higher degree. A gentleman of his acquaintance, in whose veracity he can confide, happening to be from home when a large field was limed, and having no occasion for the whole quantity of lime that had been brought for that purpose, and laid down in one corner of the field, his servants, without driving it away, mixed what remained with the soil, although the lime lay there about four inches thick over the whole surface. The effect was, that for many years afterwards, the grain in that place was so immoderately luxuriant, that it fell over, and rotted before it came to the ear. After many years this luxuriance abated a little, so as to allow the grain to ripen; but it was there always much more luxuriant than in any other part of the field. An accidental experiment, nearly similar to this, fell under his own observation. It happened that the servants of another farmer laid, by mistake, a few heaps of lime upon a grass field that he did not intend should be broken up at the time. The mistake was soon discovered, and no more lime was laid down at that place; and the few heaps (about a bushel in each) were allowed to lie neglected, without being

spread. The field was pastured upon for seven or eight years after that, before it was converted into tillage; and the heaps were by that time become so flat, and so far sunk into the ground, that they could hardly be discovered. Before it was ploughed up, the whole of the field was limed, and this part of it equally so with the rest; nor were the old heaps touched till the plough went through them in tilling the field, when the lime was there turned up, with only a very small mixture of soil. The consequence was, that at every one of these heaps, a tuft of corn sprung up with such luxuriance as to be entirely rotted before harvest; and for many years afterwards, these tufts could be distinguished from the other part of the field at a very great distance, like so many buttons on a coat; and perhaps continue so to this day. From these experiments, as well as other considerations, there seems to be reason to conclude, that on soils which do not naturally abound with chalk, or other calcareous matter, there is less danger in giving too much lime than in applying too little, except in those cases where an over luxuriance is to be apprehended previously to such limings.

It has been stated by a late agricultural writer, that in the counties of Lanark and Westmoreland, from one hundred to five hundred bushels of lime-shells, after being reduced to powder, are applied to the English statute acre; and that the bushel of lime-shells, or calcined lime-stone, generally yields from two and a half to three bushels of powdered lime; the price of which at the kilns varies from fourpence to sixpence; the general average over the kingdom being rated at fourpence halfpenny the bushel. In the county of Nottingham, the ordinary quantity does not exceed seventy or eighty bushels. In the counties of Cumberland in England, and West Lothian, Fife, Perth, Angus, Mearns, &c. in Scotland, from one hundred to one hundred and fifty bushels is the usual quantity; and this last may be stated as the general average quantity commonly used in all the other parts of the island.

It is asserted to have been often heard urged as an objection to the use of lime as a manure, that although it does indeed promote the fertility of a soil in a higher degree at first, yet, in the end, it renders it much more sterile than formerly; on which account, they say, it ought not to be at all employed. This, like many other objections to useful practices, takes its rise entirely from the avarice and unskilfulness of those who complain. It is chiefly heard of in those parts of the country where it is not common for a farmer, after once liming a poor soil, to take fifteen or sixteen crops of oats successively, without any other dressing or alteration of crops. It must be a good manure that enables these soils to produce such a number of successive scourging crops of any sort: but it would be a marvellous one indeed, if it should prevent those fields being exhausted by them. But is it not well known, that in all the richest and best improved parts of the country, lime has been long employed as a manure? Yet, so far are those soils from being rendered sterile by it, that it is doubtful if any art, without the assistance of lime, or some calcareous matter, could ever have brought these fields to their present degree of fertility. Those, therefore, who complain of the hurtful effects of lime as a manure, proclaim what they ought to conceal; that they have had in their possession a treasure, which might have enriched their posterity, but which in their own life-time they have idly squandered away.

We are, however, not only unacquainted with the mode in which the lime operates upon the soil, but we are even in a great measure ignorant of the actual changes that are produced upon the earth after this manure is applied. Is

is often asked, How long the effects of lime may be perceived on the soil? And, if by this question it be meant to ascertain the length of time that the effects of lime will be perceptible in promoting the luxuriance of the crop after one manuring, it is no wonder that very different answers should be given, as the effects must vary with the quantity or quality of the lime employed, the nature of the crops that follow, and many other circumstances, which it would be impossible to enumerate. But if it be viewed in another light; if lime be supposed to alter the soil, so as to render it susceptible of being affected by other manures in a more sensible degree, so as to make it capable of producing crops that no art could otherwise have effected, and to admit of being improved by modes of culture that would not otherwise have produced any sensible benefit, the answer to the question would be more easy, as in this light, it is pretty plain that its effects will be felt, perhaps, as long as the soil exists. It is believed farmers are seldom accustomed to consider lime, or other calcareous manures, in this point of view; although, when it comes to be inquired into, it is not doubted but this will be found to be by far the most valuable effect of these measures. A few facts will best illustrate the meaning. In Derbyshire the farmers have found, that by spreading lime in considerable quantities upon the surface of their heathy moors, after a few years the heath disappears, and the whole surface becomes covered with a fine pile of grass, consisting of white clover, and the other valuable sorts of pasture grasses. This shews that lime renders the soil unfriendly to the growth of heath, and friendly to that of clover. It is found by experience, that in all porous soils which are not exposed to too much dampness, in every part of Scotland where lime has not been employed, heath has a natural and almost irresistible propensity to establish itself. In those parts of the country where lime has been much used as a manure, we find that the fields may be allowed to remain long in grass, without becoming covered with that noxious plant. Again, it is well known by those who have been attentive, and have had opportunities of observing the fact, that peas of any sort can never be successfully cultivated in any part of the country where the soil is not of a very strong clayey nature, or where lime or other calcareous manures have never been employed. If the ground be made as rich as possible with common dung, although the peas in that case will vegetate, and grow for some time with vigour; yet, before they begin to ripen, they become blighted, usually die away entirely before the pod is formed, and but rarely produce a few half-formed peas. But if the ground has ever been limed, although, perhaps, at the distance of thousands of years before that period, it never loses its power of producing good crops of peas, if it is put in a proper tilth for carrying them at the time. Again, in countries that have never been limed, the kinds of grass that spontaneously appear, if left to themselves, are the small bent-grass and feather-grass. In places where lime has ever been used, the ground, if exhausted, produces fewer plants of these grasses; but in their stead white clover, the poa and fescue grasses, chiefly abound. The soil in either of these cases may become equally poor; that is, may produce equally scanty crops: but the means of recovering them will be somewhat different. In the first case, a fallow seldom fails to prove beneficial. In the last, it is often of no effect, sometimes even hurtful. In the last, a moderate dressing of dung produces a much more sensible and lasting effect than in the other. In the last the quality of the grass, as well as its quantity, rather improves by age. In the first these circumstances are reversed. Several other observations might be made, tending to shew that

ground, which has been once impregnated with calcareous matter, acquires qualities from that moment which it did not possess before, which it ever afterwards retains, and never returns exactly to its former state. In addition to this it is observed, that although lime has such powerful effects on the soil, it does not seem ever to incorporate with the mould, so as to form one homogeneous mass; but the lime remains always in detached particles, which are larger or smaller in proportion as it has been more or less perfectly divided when it was spread, or broken down by the subsequent mechanical operations the soil may have been made to undergo. Hence it happens, that in ploughing, if there chance to be any lumps of calcareous matter in a dry state upon the surface, they naturally tumble into the bottom of the open furrow as soon as the earth is edged up upon the mould-board, so as to fall into the lowest place that has been made by the plough before the furrow-slice is fairly turned over. In consequence of this circumstance, it must often happen that, in the course of many repeated ploughings, more of the lime will be accumulated at the bottom of the soil than in any other part of it; and as the plough sometimes goes a little deeper than ordinary, the lime that on these occasions chanced to be deposited in the bottom of these furrows, will be below the ordinary staple of the soil, it will be useless for the purposes of the farmer. It is commonly thought that the lime has sunk through the soil by its own gravity, although it is certain that lime is specifically lighter than any soil, and can only be accumulated at the bottom of the mould by the means above described: others think that the lime is chemically dissolved, and afterwards deposited there; but this idea is not corroborated by the facts that have been already brought to notice. The following directions are applicable in either case. To obviate this inconvenience, it belongs to the farmer, in the first place, to be extremely attentive to have his lime divided into as small particles as possible at the time of spreading; for, if these are sufficiently small, they incorporate so intimately with the mould, as to be incapable of being easily detached from it. On this account, as well as others, it is always most advisable to spread the lime when in its dry powdery state, immediately after slaking, before it has had time to run into lumps. It is also of importance to plough the soil with a more shallow furrow than usual when lime is put upon it, especially the first time it is ploughed after the lime has been spread upon its surface; because, at that ploughing, the lime being all on the surface, a larger proportion of it is turned into the bottom of the last made furrow than at any succeeding ploughing; and therefore more of it will be buried beneath the staple than at any other time, if the furrow shall have been very deep. This circumstance becomes more essentially necessary in ploughing grass ground that has been newly limed; because, in this case, the lime is less capable of being mixed with any part of the soil than in any other. It also becomes extremely necessary, in all succeeding times, to guard as much as possible against ploughing to unequal depths. See Anderson's Essays.

In the work on the present state of husbandry in Great Britain, it is suggested as probable, that the propriety or impropriety of repeated limings depend more on the nature of the soil, and the modes of management afterwards adopted, than on any other circumstance connected with it; and that, as in some districts it is repeated two or three times in the course of twenty years, while in others a repetition of liming, except in mixture with other substances, is found injurious, it is impossible to account for such variations in the practice or its effects on the soil, without observing, in the first place, that although there has been as yet no general rule established,

by which a farmer can determine what quantity of lime is best suited to a particular soil, yet in practice, a greater quantity is laid on strong, dense, stubborn soils, than on those of a more friable nature. In the second place, that the diversity of measures by which lime is sold at the different kilns, is often so great, as to leave it doubtful whether a farmer in one part of the island, who applies three chaldrons to the acre, does not use less than he who, in another district, applies two. And in the third place, that the quality of lime-shells is so extremely different, that in some cases the farmer who lays five chaldrons on the acre, does not apply a greater quantity of effective manure than another who limes an acre with three only. And from various circumstances which have been already noticed, in speaking of calcareous earth, as well as from the great and general advantage of this substance on all soils and situations, except such as are previously replete with calcareous matter, or too moist, the writer of the "Philosophy of Agriculture" conceives, that its effects can only be understood from the idea of its actually supplying the nutrition of vegetables. This is still further confirmed, by its contributing so much to the amelioration of the crops, as well as to their increase in quantity, as noticed by millers and bakers. If it be applied in a large quantity, it likewise kills animals in the soils, and also small vegetables, and from the destroyed and decayed animals and vegetables, the soil is rendered more fertile, by being impregnated with mucilage. The superabundant lime is useful as it becomes mild calcareous earth, by attracting carbonic acid from the atmosphere, and afterwards gradually affording it to plants. By the fermentation it brings on, and the fineness of its particles, the texture of the earth is opened and divided.

It is evident that light sandy lands, containing only a small portion of vegetable matter, should not be overdone with lime, unless we can assist them liberally with animal manures. Its great excellence on a sandy soil is its mechanically binding the loose particles, and preventing the different parts of the manure from escaping out of the reach of the crop. On clay, by means of the gentle fermentation which lime produces, the stubborn soil is opened; the manure readily comes into contact with every part of it, and the fibres of the plants have full liberty to spread. It is often said that lime answers better upon sand than clay; but let the farmer treble the quantity, and he will be convinced that lime is better for clay than sand. Clay well limed becomes a marl, falling in water, and fermenting with acids: the air, rain, and dews are freely admitted, and the soil retains the nourishment of each. In consequence of a fermentation raised in the soil, the fixed air is set at liberty, which in a wonderful manner promotes vegetation. It is the nature of lime, in its active state, to dissolve vegetable bodies. Upon this principle we may account for the wonderful effects it produces in the improvement of black moor-land, which consists of dissolved and half dissolved vegetable substances. And it may be observed in general, that the greatest quantity should be used upon the deepest and richest soils, and the least upon those that are thin and light. On strong clays and deep loams there is a substantial body for it to operate upon; consequently, a considerable quantity will be required to pervade and give due activity to the whole; but as the soil is lighter, the quantity must be less, and the after-management in regard to crops extremely cautious. In liming a single field, an attention to the quantity will often be found necessary: the soil of the higher parts being for the most part light and free, and that of the lower more deep and compact, where the ground is unequal. On some soils, particularly where the bottom is chalk, lime-stone, or marl, lime will be pernicious, especially if the soil be thin.

Whatever be the method in which lime produces its beneficial effects upon land, it should always be reduced into as fine a powder as possible, and spread out with the greatest equality upon the soil, as by these means it will be more equally blended with it, and be more extensively useful in promoting the growth of crops.

Considering lime as a substance operating upon the living substances in the soil, as well as mechanically upon the soil itself, we perceive the necessity of applying a sufficient quantity at once, in order to produce these effects: for, if the quantity employed be small, and the soil deep, its effects will be scarcely perceived. Many farmers imagine that lime will not answer upon their lands, because they have laid it on in small quantities, whereas in all probability they would have found a larger dose highly beneficial. On clay, four or five hundred bushels are laid on for wheat, but it can scarcely be expected to answer the expence. On moss, bog, moor, &c. to be reclaimed from a state of nature, the more is laid on the better it is. The beneficial effect of lime on sandy land may be explained from its binding quality. But when such lands are first broken up from their state of heath, the vegetable matter is acted upon and reduced to manure by the corrosive power of the lime. On such lands, the first crop of rye has more than paid the expences. By attracting water, lime has a tendency to lay land dry. By insinuating itself between the particles of clay, it destroys their adhesions, breaks the stiffness of the soil, and gives readier access to the operation of manures, and to the extension of the growing roots of plants. By attracting carbonic acid, or fixed air and water, and by its corrosive properties, it destroys the texture of bodies, and reduces vegetable matter to a state of manure. It unites strongly with oils, and renders them miscible with water. By being destructive to insects and vermin, it may also contribute to preserve the springing corn from their ravages.

Dr. Anderson, however, suggests, that, from writers on agriculture having long been in the custom of dividing manures into two classes, *viz.* enriching manures, or those that tended directly to render the soil more prolific, however sterile it may be, among the foremost of which was reckoned dung; and exciting manures, or those that were supposed to have a tendency to render the soil more prolific, merely by acting upon those enriching manures that had been formerly in the soil, and giving them a new stimulus, so as to enable them to operate anew upon that soil which they had formerly fertilized: in which class of stimulating manures lime was always allowed to hold the foremost rank; it would follow, that lime could only be of use as a manure when applied to rich soils; and, when applied to poor soils, would produce hardly any, or even perhaps hurtful effects. He acknowledges that he was so far imposed upon by the beauty of this theory, as to be hurried along with the general current of mankind, in the firm persuasion of the truth of the observation, and for many years did not sufficiently advert to those facts that were daily occurring to contradict it. He is now, however, firmly convinced, from repeated observations, that lime and other calcareous manures produce a much greater proportional improvement upon poor soils than on such as are richer; and that lime alone, upon a poor soil, will, in many cases, produce a much greater and more lasting degree of fertility than dung alone. In direct contradiction to the theory it is added, that he never yet met with a poor soil in its natural state, which was not benefited in a very great degree by calcareous matters, when administered in proper quantities. But he has met with several rich soils that were fully impregnated with dung, and therefore exactly in that state in which the theory supposes that lime would

produce the greatest effect,—but upon which lime, applied in any quantities, produced not the smallest sensible effect.

The author of *Phytologia* suggests the idea of its supplying actual nutrition to vegetables, which seems probable, as it contributes so much to the melioration of the crops, as well as to their increase in quantity—wheat from land well limed being believed by farmers, millers, and bakers, to be, as they suppose, thinner skinned: that is, to turn out more and better flour; which it is supposed is owing to its containing more starch and less mucilage. Hence is perceived another very important use of lime in the cultivation of land, which may be owing to its forwarding the conversion of mucilage into starch, that is, to its forwarding the ripening of the seed, which is a matter of great consequence in this climate of short and cold summers. Mr. Young, from various minutes made in his Eastern Tour, concludes, that lime agrees with almost all soils; that it fails, however, on a thin loam or lime-stone; that it seems inefficacious on old pasture; that it has a strong effect in killing weeds; but that the greatest effect is on heath and moor-lands; where, as in the peak of Derbyshire, it converts waste soils into fine pastures, without tillage: but the sort is a strong stone lime, burning soft and foamy, and the quantity laid on is very great, rising to three hundred and sixty or even one thousand bushels. There is great reason to attribute much of the benefit to quantity: in wastes especially, too much can hardly be laid on, because dissolving the roots of heath and other spontaneous growth requires a powerful agent. Of their strong lime three hundred and sixty bushels are probably equal to five or six hundred bushels of chalk lime. What then are five or six quarters, which is no uncommon quantity, laid upon an acre?

And the mode of using lime, in improving their heaths or moors, is first to pare the ground in the beginning of March, about an inch and a half thick, to turn it about in dry weather, when dry to gather it into heaps, and burn it into ashes, to spread them even over the ground, to set on their lime, to spread and harrow it altogether, to plough the ground very thin, and to sow it with turnips or rape: then the spring following to sow with oats or barley, and good grass seeds: another good dressing with lime after the first crops of seeds is got; and then it may lie for pasture. Spreading the lime in a flaked state is by far the best method. The summer months are preferred, because fewer coals are necessary for burning; in other respects, the winter months are just as good for laying the lime upon the ground, provided it be done in dry weather.

But in its application upon fallows it is found to produce the best effects when laid on early in the season, and well incorporated with the soil while it is dry and powdery.

And the assistance of this manure has been highly useful in the cultivation of turnips; whole districts, formerly useless, having been made to produce not only good crops of them, but also valuable ones of corn and broad clover. Its greatest utility would seem to be upon light soils for these crops; as, where lime is the principal manure, they seldom sow turnips, clovers, peas or beans, except upon lands that have been previously limed. Instances of this sort are often met with upon the uplands; where, if any of the broad-leaved crops are sown, where a part has been limed, and a part not, the parts where the lime has been laid will produce, it is said, a valuable return, while that which has been dugged only will hardly repay the expense of seed and labour. The methods of using lime upon turnip-lands are various. Some farmers lay it on only before the last ploughing, and plough it in without harrowing: they also lay it in heaps, hot from the kiln, without being flaked. But

probably the sooner it is laid upon the land, and the more perfectly it is mixed and incorporated with the soil before the seed is sown, the more certain and extensive will its effects be found.

But the application of this substance upon clover-ley for oats is a mode of practice which ought not to be attempted. It is generally laid on in this way in the autumn, and ploughed down in the spring, but the crops seldom repay the expense.

This substance is also used as a top-dressing in spring upon grass, or wheat and other grain; but upon the latter it is said to be dangerous, unless the lime be made into a compost with dung or earth; in this form it will not only be safe but highly useful, except upon coarse meadows abounding with rushes, and other trumpery, which it destroys by absorbing the superabundant moisture which supports them.

But upon light soils, if several white crops be taken in succession after liming, the land will be worn out; a white and green crop should be taken alternately. Upon clay lands a summer fallow is sometimes indispensable; in that case the lime should be laid on in July or August, and completely harrowed in before ploughing: two or three ploughings at least are required to incorporate it well with the soil, and a suitable harrowing after each should likewise be given.

However, about Perth in Scotland, according to the Report of that county, the quantity laid on stiff land, by skilful improvers in the low country, is from forty to fifty bolls to the acre; on light land, with a gravelly subsoil, thirty or thirty-five bolls are accounted a sufficient dose. In some parts of the carse or clay land, which is not easily stimulated, they lay on eighty or ninety bolls. It is sometimes laid on fallows, immediately before the seed furrow; on barley and grass seeds, either before or after the barley is sown; and in some cases with the preceding crop, where turnips are cultivated, to prepare the ground for barley. Lime is in some instances mixed in compost dung-hills, in others it is spread on the green sward, before the land be broken up from grass. One infallible maxim with regard to lime is, that the longer it is kept near the surface, at least within reach of the plough, until it be intimately mixed with the soil, and its virtues imbibed, so much the better. The first liming of land has always a more powerful effect than it has at a future but no distant period, the quantity being equal. Quick lime intended for wheat, after a fallow, or for barley and grass seeds, might be ploughed in with a very shallow furrow, before the seed is sown: for oats after ley, it ought to be laid on during the preceding autumn; and for pasture or a top-dressing, early in the spring or autumn, rather than in summer or in winter; because, if the summer be dry, the grass is burnt up by the lime, and in winter its virtues are lessened by the frost, nor does it so powerfully attract the influence of the air. It is common, but perhaps difficult to be accounted for, when lime is spread on short heath or other barren ground, which has a dry bottom, to see white clover and daisies rising spontaneously and plentifully, the second or third spring afterwards, where not a vestige of either, nor even a blade of grass, could be discovered before it was applied. Dr. Darwin remarks that he has been informed, that if a spadeful of lime be thrown on a tussock, which horses or cattle have refused to eat for years, they will for many succeeding seasons eat it quite close to the ground; which is owing, he suspects, to the grass containing more sugar in its joints, or to the less acidity of all its juices.

Where lime is to lie in a heap for any length of time, it should

should be covered with earth, to preserve it from the air and rain. It has been observed, that the benefit of lime is not apparent in a dry summer, and that it does not act fully as a manure, till it has been thoroughly flaked in the soil, by continued rains. In Essex an excellent practice prevails, of forming a compost of lime, turf, and ditch earth, at the gate of every field, ready to be applied as a manure when wanted. Twenty bushels of lime mixed with forty bushels of sand form an excellent top-dressing for an acre of wheat, if laid on early in the spring. But lime, as first noticed, is apt to subside beyond the depth of the common furrow; deep ploughing in this case is the only remedy applicable. In some midland counties a fallow is seldom made without being dressed with lime, under an idea that it mellows the soil, and makes it work well, while in tillage; and sweetens or improves the quality of the herbage when laid down to graze. For this purpose it is fetched eighteen or twenty miles. And two sorts of lime are in use in some districts, as about Derby. The Breendon lime, burnt from a very hard stone, and of singular strength as manure; and the common lime, burnt from common stones, and called Ticknall or Walsall lime. The load-heaps are generally watered as they are thrown down from the waggon; and always turned over to complete the falling more effectually. If a quantity of lime be fetched in autumn or early in winter, to be used in the spring, when team-labour is more valuable, it is thrown up into a regular roof-like heap or mound, and thatched as a stack; a small trench being cut round the skirts to catch, with an outlet to convey away, rain water. Thus the heap is prevented from running to a mortar-like consistence by the snows and rains of winter, and thereby rendered more useful as manure.

In the Rural Economy of the Midland Counties it is noticed, that a turnip fallow was manured with Breendon lime, in general five quarters to an acre; part had double that quantity, and part had none. The turnip crop received no obvious advantage, but its effects on the barley were evident. The part not limed was the worse crop, nearly in the proportion of four to three. But the part limed with ten quarters to an acre was the best crop. Whence the common notion, that more than five quarters of Breendon lime to an acre is ruinous to crops, seems to be ill founded. And in the Economy of Norfolk, lime is said to be in good repute, though not in general use as a manure; different opinions being entertained respecting the value of it. This difference of opinion will ever remain, while general conclusions are drawn from particular incidents. It is used by many judicious farmers, even after marle, with success. Upon hot burning soils it is generally found of the greatest efficacy, and is perhaps the most effectual cure of scalds or burning patches of land that has yet been discovered; from these and other circumstances lime is there considered as a cold manure. The general method of applying lime is to let it fall in large heaps, and to spread it out of carts upon fallowed ground either for wheat or barley. The quantity set on is about three chaldrons an acre; the price 9s. or 10s. a chaldron. (Now much higher.) From experiments made on turnips, barley, and wheat, it appears that lime does not act as a manure until it has been thoroughly flaked in the soil; and it seems as if the rains of summer were necessary to promote its operation. But in some parts of Yorkshire lime is used invariably on every species of soil; and in most cases with great success. On the higher and more dry lands its utility is evident. At Malton it is laid on the calcareous quarry soil with success. Its use to the loose sandy soils is fully established. The prevailing crop is wheat on fallow. It is also pretty gene-

rally set on for rape, turnips, or other crops, after sod-burning, and spread among the ashes. It is also sometimes set on for barley. But its effect on the first crop, except of wheat or rape, is seldom perceptible.

But the benefit of lime to graze is a matter of dispute; it is even thought by some to be detrimental. It seems, however, to be a generally received idea, that lime laid on graze is not thrown away; for, whenever the land is turned up again, its benefit to corn will have full effect. The methods of liming are various. The worst is laying it in large heaps, and suffering it to run to a jelly before it is spread. Next to this, is setting it about the land in small hillocks; for, although they are spread before they approach to a state of mortar, yet this method is injudicious. Lime falling in the open air breaks into small cubical masses, which being once buried in the soil, remains in it for ages, without being mixed intimately with it. Lime ought therefore to be spread in a state of perfect powder. It is therefore the practice of judicious husbandmen to set lime upon the land in load-heaps, and spread it over the soil out of carts, as soon as it is sufficiently fallen. Or the load-heaps are turned over, not so much to finish the falling, as to gain an opportunity of burying the granular surface of the heaps; by which means, the fragments are at least lessened, if not reduced to powder. In the moor-lands the heaps are interlayered and covered up with moist turf or peat-mould, which bringing on a rapid fall, the whole is set on fire, and the surface kept free from granules by a covering of dry ashes. The heaps, therefore, whether great or small, should be covered up with soil, either of the field they are set in, or that of lanes or ditches carried to them for the purpose; and if a speedy fall be required, water thrown over this covering. If lime be used on fallows for wheat, it is generally spread in July, harrowed in as fast as it is spread, and ploughed under with a shallow furrow, as soon as convenient. The usual quantity is three or four chaldrons to an acre.

And "much depends upon the mode of applying the lime to the soil after calcination, according to Dr. Anderson. If it is spread as soon as it is flaked, while yet in a powdery state, a very small quantity may be made to cover the whole surface of the ground, and to touch an exceedingly great number of particles of earth; but if it is suffered to lie for some time after flaking, and to get so much moisture as to make it run into clods, or cake into large lumps, it can never be again divided into such small parts; and, therefore, a much greater quantity is necessary to produce the same effect, than if it had been applied in its powdery state. But if the soil is afterwards to be continued long in tillage (as these clods are annually broken smaller by the action of the plough and harrows), the lime must continue to exert its influence anew upon the soil for a great course of years: it will produce an effect nearly similar to that which would be experienced by annually strewing a small quantity of powdered lime over the surface of the soil; but as the lime must, in the first case, be paid by the farmer altogether at the beginning, which only comes to be successively demanded in the other case, this deserves to be attended to, as it may become a consideration of some importance where lime is dear, and money not very plentiful."

And it is constantly an object worthy of attention to remove the shells as soon as possible after the lime is drawn from the kiln; for it is known from experiment, that a ton of lime exposed twenty-two days to the air after calcination, is augmented in weight to thirty hundred weight, and some kinds of lime even to thirty-five; which is little less than double.

In order to understand the goodness of lime, it is remarked by the same writer, that the lime from pure lime-stone is always of a bright white, when perfectly calcined without a tendency to any colour. When it has any colour it proceeds from the sand, or other uncalcareous matters in its composition. There are, however, some sorts of sand that are of such a pure whiteness, as not to debase the colour of the lime in the smallest degree; but these are rare; and there are some matters that alter the colour of the lime a good deal, without debasing its quality in any considerable degree; but these are still more rare than the former. Hence it follows, that the best lime for the purpose of the farmer, is that which is lightest, softest to the touch, and whitest. Softness to the touch is not, however, it is conceived, an unequivocal proof of the purity of the lime. He has seen one kind of lime that contained a large proportion of an uncalcareous impalpable powder, that was as soft to the touch as the purest lime; but this was a singular exception to the rule that is very general. The more they deviate from either of these tests of purity, the worse they are for the purposes of agriculture. But if the lime-stone loses much of its weight in calcination, and the lime-shells are extremely light; if the shells require a very large proportion of water to slake them fully; if it is long before they begin to fall: if the lime-stone is not apt to run (or be vitrified) in the operation of burning; if it falls entirely when it gets a sufficient quantity of water, after it has been properly calcined; if it swells very much in slaking, and if the lime is light, fine to the touch, and of a pure white, it may be concluded that it is extremely good, and may be used in preference to any other lime that is inferior to it in any of these respects. These rules are perfectly sufficient to decide as to the comparative value of any two kinds of lime that may be proposed to one another, and may be relied upon as sufficiently accurate for the ordinary purposes of the farmer.

There are other methods by which the qualities or goodness of lime may be ascertained with exactness, but which are best performed by an expert chemist.

Proper Season for using Lime. In respect to the most proper time of using lime to lands, there seems some difference of opinion among farmers, as well as to the state in which it should be used; some supposing the best time to lay it on dry soils intended for turnips, is in autumn, while others think the beginning of summer, as May and June, better. Some, likewise, contend that it should be applied before it has been slaked; while others think it may be employed when even in a state of considerable moisture. The writer of the Farmer's Calendar, after putting the question, whether lime burnt in January should be then used or kept till spring, observes, that "there are two motives for burning stone or chalk; one is, for the sake of reducing the material to powder, for accuracy in spreading; the other is, for the application of a caustic body destructive of living vegetables. For the former purpose, the lime had better be kept; for the latter, it is usually laid on in such large quantities that it is not very material at what season it is spread, provided it be done fresh from the kiln. It will have a greater effect in spring and summer, but the superiority is not such as to induce delay from a time in which the teams have little to perform, to a season in which there is much work for them." And he further states, that "the grand effect of this manure is on uncultivated waste land. On moors, mountains, bog, and boggy bottoms, the effect is very great, but the quantity applied is considerable. The more the better. In Derbyshire, as far as 600 bushels an acre have been used; or 20 one horse cart

loads of 30 bushels: such a dressing, when the space to be improved is large, demands the employment of regular teams to be kept continually at work. In such undertakings, it is idle to be nice about the season of applying the manure; convenience demands that the work should go on at all seasons, but in the counties where lime is most used, the common season is summer, and on fallows."

And there cannot be any doubt but that it is the best practice to apply it either in the spring, summer, or early part of the autumn, and in a state as little moist as possible, as, under such circumstances, it may not only be laid on with the greatest convenience, but be spread out in the most even and regular manner, which is a point of considerable importance in this husbandry, and be laid on with less injury from treading the land, than could otherwise be the case.

The above writer also states, that "liming is, in many districts, connected with paring and burning, and it is one of the best methods of applying this manure. From a peck to a bushel, according to its plenty, is added to, and mixed with, every heap of ashes, and they are then spread together. The effect generally is considerable, but proportioned to the soil. The greatest effect of this manure is upon land that has been long in a state of nature; and particularly upon all peat soils, moors, mountains, and bogs. But upon all on which it is known to have effect, it is well applied in the ashes of paring and burning."

But though the application of this substance properly belongs to the occupiers of lands, it is necessary that the proprietors of them should render it as easy and convenient as possible, "either by searching for raw materials, opening quarries, and erecting kilns upon the estates under their care, or by bringing, from a distance, materials, fuel, or lime itself, at the least possible expence, through the means of improved roads, rail-ways, or water-carriage." And that the same principle holds good "with respect to marles, and other gross substances, to be used in their raw state; as the advantages arising therefrom will always, eventually, find their way into the rent-roll."

Doctor Anderson thinks it may be necessary to observe, that when farmers employ a great deal of lime, it sometimes happens that their horses' feet are burnt by it; which is extremely troublesome, and sometimes proves even fatal to the poor animals: a method of preventing or remedying that inconvenience will, therefore, be of use. The best method of preventing any inconvenience of this sort is to spread the lime, when in its powdery state, upon the field as evenly as possible, and to allow it to lie in that state some time before you begin to plough it. If the lime has been in fine powder, it will have become perfectly effete in a week or so; after which time it will be as little corrosive as any kind of common earth, so that the horses may work among it with perfect safety. But if it has been suffered to run into clods before it was spread, these, if not broken small, will be longer in absorbing their air, and, of consequence, will remain longer in an acrid state, so that the ploughing may, in that case, be deferred for a week longer, nor will it be even then so perfectly safe as the other. But if it becomes necessary at any time to plough in the lime immediately after it is spread, take care, says he, to do it only when the soil is perfectly dry; and in leading your horses to the plough, take care to prevent them from going through any wet place, so as to wet their hoofs or ankles; for lime acts not at all upon any dry substance; but when it is in its acrid caustic state, it will corrode the hair and flesh in a moment, if it has access to water. As soon as the horses are unyoked, keep their feet dry till you have got them

them carefully brushed, so as to wipe away all the dry powdery lime that may adhere to them; and if the least shower should fall, unyoke your horses immediately, and take them off the field. With these precautions, they may work among lime for any length of time, without receiving any damage whatever.

However, in case of any accident, by which a horse or man that is working among lime should be scalded by it, it is always advisable for every farmer who has work of that kind going forward, to keep a tub of very four milk, or whey, in some place ready to wash the part affected well with, which will quickly destroy the poignancy of the lime, and prevent the mischief that would otherwise arise from it. The sourer the milk or whey is, the better it will be for this purpose; it ought, therefore, to be long kept. For want of this, vinegar may produce the same effect, or very stale urine will be of use; but the milk or whey is the cheapest and best remedy, and ought always to be in readiness where lime husbandry is going on to any extent.

LIME, in *Botany*. See LEMON.

LIME-*Ammoniacal*, a kind of phosphorus, invented by Mr. Homberg, and made of sal ammoniac and lime. See *Ammoniacal PHOSPHORUS*, and LIME, *supra*.

LIME, *Bird*. See BIRD-lime.

LIME, *Brook*. See BROOK-lime.

LIME, *Burning*, a term signifying the process of converting lime-stone, chalk, marble, shells, and other calcareous substances into lime, by means of heat, in kilns properly constructed for the purpose. See KILN.

In these cases, the calcination is effected by different sorts of fuel, in different situations, but principally by fossil-coal, peats, or woods; these being laid in layers, alternately with those of the calcareous materials, in the kilns, and the process of burning continued for any length of time, by repeated applications of fuel and calcareous matters at the top, and drawing out the lime from below occasionally as it is burnt.

But mineral coal, or culm, are unquestionably the most convenient and suitable materials for effecting this business, where they can be procured in plenty, and at a sufficiently cheap rate, as they burn the stone, or other calcareous matter more perfectly, and, of course, leave fewer cores in the calcined pieces than when other sorts of fuel are employed for the purpose.

However, Mr. Dodgson has had much success in burning lime by the use of peats; as he states, in the *Farmer's Magazine*, that he is "convinced, from experience, that lime-stone can be burnt to better purpose, and at less expence, with peat than with coal. When coal is used, the lime-stones are apt, from excessive heat, to run into a solid lump, which never happens with peat, as it keeps them in an open state, and admits the air freely. The process of burning, also, goes on more slowly with coal. No lime can be drawn for two or three days; whereas, with peat, it may be drawn within twelve hours after fire is put to the kiln; and in every succeeding day nearly double the quantity of what could be produced by the use of coal. The expence is comparatively small. A man and a boy will dig as many peats in one day as will burn 60 Carlisle bushels of lime, (the Carlisle bushel is equal to three Winchester ones,) and the expence, including drying, will not exceed four, or, at most, five shillings; while the coal necessary for burning the same quantity of lime would have cost twelve shillings at the pit. The wetness of seasons is no argument against the use of peats, as they can be stacked near the kiln, when half dry, at any time of summer; the moisture will be exhaled from

them during winter, and they will be in a fit state for burning in the months of April or May. He lives in the north-eastern district of Cumberland, where the farmers, in general, burn their own lime; and though there is coal in the immediate neighbourhood, he gives a decided preference to peat, for the reasons above-mentioned." And it is well known, that this kind of fuel has been occasionally used in many parts of the kingdom for the same purpose, from a very early period, without any complaint of the want of success.

In the practice here stated, no particular form of kiln was found necessary, nor any particular sort of management in the process of calcination; the proportion of peat depending upon the nature of the lime-stone employed, and other circumstances.

It has been considered by Mr. Marshall, that "the manufacture of lime is an art of which the manager of an estate ought not to be ignorant." And he conceives, that "he ought to have, at least, a sufficient knowledge of its theory, to enable him, when occasion requires, to superintend or direct its practice. For it seldom answers, unless where materials are plentiful and fuel cheap, for every tenant upon an estate to manufacture his own lime. A full-sized kiln accumulates a stronger heat, with a given proportion of fuel, than a small one of the same form," which is without doubt a great saving.

It is supposed, that "the chief or sole intention of burning lime-stone for manure, appears to be that of reducing it in the readiest and cheapest manner to an impalpable powder. For experience sufficiently shews, that quick lime is injurious, rather than beneficial, to vegetation; and that burnt lime-stone does not operate as a manure until it has regained the fixed air, of which the fire deprived it. If it could be reduced by mechanic powers to powder of equal fineness, its effect, as manure, would doubtless be the same as that of dead lime (effete). It is in the perfect solution which well-burnt lime-stone has received, by the expulsion of its fixed air in the fire, so as to have completely loosened its texture, and unbound its every atom, that we are to look for its prompt effect and the shortness of its duration, comparatively with unburnt calcareous substances. Hence the main point to be attended to is to expel the whole of the air. For, unless this be accomplished, the solution becomes imperfect; the stones, instead of completely dissolving into impalpable atoms, break into granules, or flakes; leaving, perhaps, a firm core in the centre, to encumber, rather than to fertilize, the soil" on which they are applied. "There is, however, an opposite extreme to be avoided, and with greater care. For an unburnt stone may be returned to the kiln, but one which, by too intense a heat, is vitrified, or changed to a state of impure glass, is not only rendered useless, but has incurred an extraordinary waste of fuel. Consequently, stones that are prone to vitrification ought to be broken down into small pieces; otherwise, the fire is required to be so intense, that the surface becomes vitrified, before the air from the centre can be expelled." And "another suggestion, respecting the proper size of the stones to be burnt, may have its use. Where fuel is weak, or dear, the materials require to be broken into smaller fragments, than where a strong fire can be kept up at a small expence; while, under the latter circumstance, and where the stone is not prone to vitrification, much of the labour and expence of breaking may be saved, by using an extra quantity of fuel, and keeping up a strong fire in the kiln," or place where it is burned; the form or construction of which depends partly on the qualities and value of the materials, and partly on the kinds of fuel that are made use of, and the

the differences of their prices at the places where they are employed. See KILNS.

It is useful that the process of burning lime should go on during January and February, as well as most of the winter, and also in the summer months. Perpetual kilns are wrought in many districts, especially the northern ones, and in Ireland; the lime, when not taken away, being preserved, in sheds erected for the purpose, from the wet. The usual mode of managing with them is, for the farmers to contract for some sort of measure, according to the custom or practice of the particular district; being careful that it is well burnt, and of a proper quality in other respects. The differences in the expence of burning will depend on the abundance or scarcity of fuel, and the convenience of the stone for carriage.

LIME, *Calx, Calx viva*, in the *Materia Medica*, &c. is prepared by breaking a pound of lime-stone into small pieces, and heating it in a crucible in a very strong fire for an hour, or until the carbonic acid is entirely driven off, so that on the addition of the acetic acid, no bubbles of gas shall be extricated. Lime may be made by the same process from shells previously washed in boiling water, and cleared from extraneous matters. In the former pharmacopœias lime was ranked among the articles of the *Materia Medica*, and taken as prepared for its uses in the arts; but in the last London Pharmacopœia particular directions are given for obtaining it in a purer state. Two varieties of the carbonate are selected from which it may be prepared, *viz.* lime-stone and shells of oysters; the latter of which contains the least foreign admixture; but even the former, thus prepared, will be much purer than that which is usually made from chalk. According to Kirwan, carbonate of lime consists of 45 parts of carbonic acid and 55 of lime: but from whatever combination it be obtained, lime is always the same substance, possessing the same characters, and producing the same effects, though it may be different with regard to the proportion of heterogeneous matters with which it is mixed; and, therefore, the distinctions which were formerly made between its medical qualities, as obtained from different sources, were superfluous, and will not, in the present state of science, be likely to be renewed by the introduction of more than one. To the perfection of the lime it is necessary that the carbonic acid should be entirely expelled; but in the preparation of ordinary lime this is done very imperfectly; for to all common purposes it is sufficient if it be burnt so as to flake on the addition of water; on the other hand, it may also be noticed that where lime-stone is employed, the heat may be urged too far and be too long continued. The pure earths will not vitrify by heat, but many earthy admixtures readily will; and as most lime-stones contain some portion of other earths, they may, under these circumstances, vitrify, and form a coating over the surface of the lumps, which will defend them from the action of water, and thus prevent their slaking or solution; so that lime may thus be over-burnt. The pieces of stone used for burning should be as nearly as possible of equal size. If half its weight of water be poured upon lime, it swells and falls into a white powder, much heat is evolved, part of the water rises in steam, and part combines with the lime; this is called slaked lime, and in this state carbonic acid from the air easily attaches to it. When perfectly dry it may be kept in bottles for any length of time without alteration; but to obviate any chance of its being impure from the above cause, it is usual to direct its being employed newly prepared. Lime newly slaked, and to which more water is added, ought not to effervesce on the addition of an acid.

Lime is much used by tanners, skinners, &c. in the preparation of their leather; by soap-boilers for dissolving the oil, and facilitating its union with the alkaline salt; and by sugar-bakers for refining their sugar.

It is also of some medicinal use; being applied externally in defecative and epulotic medicines.

It is used also as a depilatory; and has been sometimes made into an unguent with honey for rheumatic and other obdurate fixed pains of the joints or limbs: this unguent is much commended by Fuller, who observes, that it is almost caustic. As an absorbent earth, it is anti-acid, and capable of absorbing the acid matters which are produced in digestion from the weakness of the stomach, in diseases proceeding from a spontaneous acid, so well described by Boerhaave. It is the fitter in these diseases, which are commonly the effect of the inactivity and weakness of the fibres, as it possesses a tonic quality, which other absorbent earths have not. Besides, persons afflicted with these diseases are subject to much wind, which is, perhaps, nothing else but gas; and quick lime is very capable of absorbing that fluid. As quick-lime is also drying, a little caustic, and consequently cicatrizing, it may contribute to cure certain ulcers, especially those of the soft parts. Accordingly, several able physicians have preferred it successfully for internal suppurations, and in the phthisis pulmonalis. Moreover, the property which quick-lime has of attenuating viscid matters, and of decomposing ammoniacal salts, has been advantageously applied to dissolve stones in the bladder and kidneys. But the best method of administering quick-lime internally has been thought to be by giving the lime-water; because this water is supposed to possess all the medicinal virtues of quick-lime, and because the earthy particles are thus reduced to the greatest fineness, and are, consequently susceptible of the most perfect distribution. However, this should be administered with great caution, and much diluted; and, after all, it is doubted, whether the lime-water, thus diluted, has all the medical qualities which might be expected from quick-lime. Macquer.

LIME, *Carbonat of*, a term applied to lime when slaked or in the state of lime-stone: when thus saturated it is in the least active condition. See **LIME-STONE**.

LIME, *Cream of*. See **CREAM**.

LIME Effete, that which has been slaked by the air and moisture of the atmosphere after long exposure.

LIME-Galls, in *Natural History*, a sort of galls or vegetable protuberances, formed on the edges of the leaves of the lime-tree in spring time; they are very common in the plantations of limes, and are irregularly shaped, but usually oblong and rugged, and of a reddish colour; they occupy only the edges of the leaves, and are of a red colour, sometimes very beautiful. As these are very plentiful, M. Reaumur was of opinion, that they might be of service in the dyeing trade; he made trial by rubbing them on some parts of his linen, and found that they gave a very beautiful red colour, which did not come out in the first washings afterwards. It is extremely probable, that there wants only inquiry to prove that we have many valuable productions of this kind, which, though disregarded at present, might prove of great use in the several mechanical arts as well as in medicine.

These galls of the lime-leaves are formed by a worm, which inhabits them during its term of life, being found in them of all sizes, from the most minute to that of the full growth, which is about half an inch in length; but when its period of life, as a worm, draws near, it deserts this habitation, and goes elsewhere to pass into its chrysalis state. See **GALLS**.

LIME Husbandry, a term used to signify that sort of management which relates to the application of lime on land. See **LIME**.

LIME-Kiln, a sort of kiln, constructed for the purpose of burning lime. Kilns of this nature are formed in a variety of different ways to save expence, and answer to the particular nature of the fuel. See **KILN**.

LIME, Quick, a term applied to lime in its most powerful or caustic state, before it has been rendered mild by the absorption of carbonic acid gas, or fixed air, from either the atmosphere or the soil.

LIME-stone, in *Agriculture*, a kind of calcareous stone, which is capable of being converted into lime by means of calcination. It would seem from the remarks that have been already made, in speaking of the nature of lime, that this sort of stone exists in different states of purity, and consists of different sorts of substances in different situations, from which much diversity in its effects, when converted into lime, is produced; some sorts being more proper for the purposes of agriculture, while others are better adapted to those of building, &c. See **LIME**.

It may be worthy of remark, that all such sorts of lime-stone as contain impurities, such as clay, sand, or stony matter in their compositions, are more proper in general for the purposes of agriculture, than for those of building. Where lime-stone is plentiful and fuel scarce, it might be employed for the purpose of husbandry with great advantage in its uncalcined state, after being pounded or ground into a fine powdery form, by means of mills or other machines. And it is stated in the Survey of the County of Perth, that in Rannoch, a district of that county very remote from coal, a machine was erected by the late commissioners of annexed estates for this purpose, which was driven by a stream of water. Mr. Stewart, of Crosmount, who saw the machine, the pounded lime-stone, and its effect on the land, favoured the author with the following remarks; "There were two pounders, and a third was afterwards added, all from Carron, at a small expence. The pounded lime-stone was carried from the machine by a small run of water to three different ponds, one above the other. The upper pond contained the grossest particles, and the lower pond the smallest or finest parts of the lime-stone, which resembled clay or marl from its smoothness." The middle pond contained that which, it would appear, Mr. Stewart thought to be properly pounded; because he adds, "the run of water might have been stronger, which would have enabled the mill to double the quantity grinded, which would serve the purpose of manure equally well, if not better, than by being pounded so very small. All that was pounded before the machine was carried off by a flood, or the most of it, was used by colonel Alexander Robertson, uncle to the present colonel Robertson of Struan, who had a farm in the neighbourhood of the mill. The effects of it were visible upon the ground, which were shewn by the colonel to different gentlemen, and approved of. It seems, however, that before its virtues could be fully ascertained by repeated and varied experiments, a torrent in the brook that drove the mill carried all the machinery away, or at least deranged it so that it was never restored. There is, it is supposed, little doubt of its beneficial effects on land; or of its effects being more powerful, in one shape or other, than those of the same quantity of calcined lime-stone, because the virtues must be in proportion to the quantity of calcareous earth in each. Any given quantity of raw lime-stone loses one-third of its weight when burnt into shells. Nothing is here dissipated except the water; all the calcareous earth remains. It is also found, that any

given quantity of shells produces double that quantity of powdered or flaked lime. Therefore, a quantity of raw lime-stone, a bushel for instance, has double the quantity of calcareous earth which is in a bushel of flaked lime: consequently its influence as a manure must be double. What is commonly supposed, and the writer thinks with probability by those who used both kinds, without making any accurate experiments, is that the effects of the raw lime-stone are slow, but more lasting; of the calcined lime, more immediate, but less durable.

And it has been stated in a periodical work, that "the difference between lime-stone, fresh from the rock, and that which has been calcined, consists in the former possessing, as one of its principal component parts, a very considerable proportion of fixed air or carbonic acid, a principle of which it is entirely deprived in the burning, if the operation is properly conducted; a circumstance well worth the attention of proprietors, as, in that state, its beneficial effects consist chiefly in the power it possesses of neutralising acids, or decomposing metallic oxyds; but upon the animal or vegetable substances it meets with in the soil, it can produce no alteration." For "many years ago, an attempt was made by lord Kames to use unburnt lime-stone as a manure; the success of which, it is believed, has not been recorded; indeed, the trial would probably, it is supposed, prove abortive, if made upon meads, or moorish lands, which, owing to the great quantity of vegetable matter they contain, cannot possibly be benefited by any substance possessing less activity than quick or caustic lime."

A machine for this use, that admits of being wrought by steam, wind, water, or the power of horses, is represented in *Plate Agriculture*, in which *a* represents a beam, supported by four strong posts joined together by transverse pieces of wood, as seen in the figure, and at the top sufficiently separated to allow the wheel to work; *b*, a wheel with a groove on the circumference, sufficiently deep to receive the beam *a*, with a large iron spindle or axis, moveable in a bush made of bell metal; *c*, a weight of a conical shape, of cast iron; the base studded with knobs or protuberances, about two inches long, or a diamond shape, terminating in a blunt point, and about five inches in circumference at the bottom; *d*, the face of the weight or pounder, which is hidden from view in the cut; *e*, a circular building sunk below the surface of the ground; the bottom prepared by a stratum of clay, well tempered, and mixed with a proportion of burnt lime-stone, powdered without being slacked, and forge ashes beat very small. When this is properly dried, a bed of sand, about 18 inches in thickness, is laid about it, and paved with common paving stones, of the kind used for streets; which, after being well beaten down, is covered with another bed of sand of the same thickness, which should be paved in the same manner, and afterwards well beaten down. The foundation of the building should be, at least, six feet below the common surface; which allows 18 inches for the clay, 30 inches for the two beds of sand, and 18 inches for the two courses of pavement. And the "circumference should consist entirely of hewn stone, at least the uppermost three feet of it; the stones of which should be strongly battled together with iron, and secured on the outside with numerous wooden posts drove into the earth, and different courses of pavement, extending at least six feet all round, carefully laid and well beaten down. A floor prepared in this manner, if it is not used too soon, will resist any force that can be let fall upon it. The lime-stone laid into it should not be too small, and should have a light bedding of sand, in soil, to give it stability. The building may be of any size, according to the powers

powers of the machinery, and the weight of the heater." Others have suggested, that the pounding of lime-stone may be greatly facilitated by a very simple contrivance; merely that of kindling a fire upon the surface of the rock, or round any quantity of the lime-stone after it is quarried, and exposing the stone to the heat of it for ten or twelve hours. During the heating, a great deal of it flies to pieces, and the remainder very readily gives way to the stroke of the hammer. It is also supposed, that considerable advantage may be derived from a machine of this kind, in reducing burnt lime-stone to a powder, before it is slaked by the action of the air or moisture, as, in that state, its operation upon the substances it meets with in the soil is much more considerable than after it has absorbed the fixed air; and when employed in building, it cements immediately, and may be used with equal advantage in the construction of aqueducts, pavements, and other situations exposed much to water, and where hard dryness is of importance.

It may be noticed, that the expense of such a machine will vary according to circumstances, but it cannot be great, and in many places it may be added to thrashing and corn mills, and the expense be scarcely noticed in that way.

It is obvious, that the analysis of lime-stone may be effected in the same way as that of other calcareous materials, except that where the stone is of a hard and firm texture, it should be reduced to a state of powder, in order to expedite its solution. Where the lime-stone subjected to analysis does not yield more than two-thirds of its weight of pure chalk, it can seldom be burnt with profit; unless in a country where fuel is cheap and lime is dear. Good lime-stone yields upwards of ninety *per cent.* That of particular quarries is almost wholly calcareous, as has been already seen.

Lime-stone Gravel, a hard sort of calcareous marble, that assumes the appearance of small stones or gravel, which, when spread upon the ground and mixed with it, gradually falls into smaller pieces, and fertilizes the soil in proportion as it breaks down and mixes with it. It is a sort of manure little known in Britain, although it is common in many parts of Ireland.

But after what has been already observed, little need be said as to the qualities or mode of applying this manure. The farmer will easily be able to perceive, that if the pieces of which this gravel consists are large, and dissolve but slowly, the quantity applied at one dressing ought to be great, and the effects will be slow and lasting; but if the gravel be small, it will require a smaller quantity, which will operate more quickly, and last for a shorter time, like all other calcareous substances in the same circumstances, or which are applied in the same manner to lands.

Lime-stone, in Mineralogy. See LIME.

Lime-stone, Aqueous. See DELOMITE and RHOMBSAR.

Lime-stone, Quartz. See KONT.

Lime-stone, Rock. See SWIN-STONE.

Lime-stone, Precipitate. See ARAGONITE.

Lime-water liquor calis, aqua calis, aqua calis simplex, or the *American Solution*, is prepared by pouring twelve pounds of boiling distilled water on half a pound of lime, and stirring them together; let the vessel be immediately covered, and left to stand for three hours; then keep the solution upon the remaining lime in stoppered glass bottles, and pour off the clear liquor when it is wanted for use. Lime is soluble in about 45 times its weight of water, or little more than one gram in one fluid-ounce, forming a transparent solution; hence the proportion here directed, is in fact more than is required for the saturation of the water; but the larger quantity

allows, moreover, for any impurity contained in the lime, and as it is a cheap article, the quantity used is scarcely of any importance. The process here adopted is simple, efficacious, and convenient, and by keeping the solution standing upon the lime it will always be saturated; and the place of any small of evaporation of lime which forms upon the surface, if exposed, will be supplied from the lime, which remains in a state ready for solution. *London Pharm.* 1829.

The general opinion of lime acting as a caustic, and consuming the bodies it was made to act upon, by means of the great quantity of particles of fire it contained, long denied any preparation of it a place among internal medicines; at length, water poured upon it was found to take in a part of its virtues, and to be a valuable medicine, and very safely to be given internally in large quantities.

For this purpose, a gallon and a half, or two gallons of water, were poured by degrees upon a pound of fresh-burnt quick-lime; the vessel shaken when the ebullition ceased, and then set by, till the undissolved lime had settled; after which, the liquor was poured off, and passed through a filter. Only a small portion of the lime is dissolved by the water, and the remainder gives a strong impregnation to large quantities of fresh water, though not so strong, as the first; great part remaining at last undissolved; this sediment, calcined again, becomes quick-lime, as before; and by repetitions of this process, nearly the whole may be dissolved. The solution has a strong styptic taste; and its effects in chemical mixtures are similar to those produced by quick-lime. In vessels quite filled with lime-water, and exactly closed, it may be kept unchanged for many months; but in open vessels, the calcareous matter soon separates from the aqueous fluid, and forms a crust or cream upon the surface, insipid and indissoluble as the earth in its natural state, and again convertible into quick-lime by repeated calcination. It is observed, that the quantity of calcareous matter that is thus separated from lime-water, is even greater than it ought to be, if it was exactly proportioned to the evaporation of the water; the cause of which is, that the quick-lime gradually recovers from the air as much gas as is necessary to deprive it of its properties of quick-lime, and to restore it to its state of impure calcareous earth, mild, effervescent, and insoluble in water. Hence lime-water by long exposure to air, loses most of its strength, and at last becomes almost insipid. It is necessary also, when this liquor is employed as a menstruum, to add some quick-lime in substance, in order to continue the impregnation of the water with the lime.

All lime is not equally good for the making of this water; but the several kinds differ, according to the substances they are made from. In Holland they make lime of sea-shells, which they find in vast abundance on their sea-shores. This was also a practice in the time of Dr Boerhaave; but the lime thus made, it has been said, is not fit for making lime-water. The water made from it does not keep long, and is less styptic and fortifying to the taste, and is greatly inferior to the water made with lime burnt from stones. The newer the lime is, the less it has been exposed to the air, and the drier it has been kept, and finally, the more it has held together without crumbling, or mouldering to powder, the better it is for making lime-water. *Mém. Acad. Par.* 1700.

It appears now, from the ingenious Dr. Allen's experiments, that one part of quick-lime is sufficient for five or six hundred parts of water. Water will dissolve but a certain portion of quick-lime; and how much that is cannot be easily ascertained. So far seems certain from Dr. Allen's experiments, that one pound of quick-lime is sufficient for making

making six hundred pounds of good lime-water; and that those who with Charas have supposed, that the second and third lime-water is weaker than the first, have been led into an error by the small quantity of water they used. And it has been generally believed, that in order to obtain good lime-water, the quick-lime must not only be recent and fully calcined, but also for one part of quick-lime only eight, ten, or, at most, twelve parts of water taken; as if it could impregnate no more. But the doctor says he has found, by many experiments, that it is altogether indifferent whether the water be hot or cold, poured on gradually, or at once, the water poured on the lime, or the lime thrown into the water; whether the quick-lime be in shells or flaked; or even exposed to the air for several months, the such quantities of the water as are commonly used; and if the quick-lime be fresh, whether for one pound of it, eight, ten, twenty, fifty, or five hundred pounds of water be taken. Only it is necessary, even for the first water after the ebullition is over, to stir and mix the lime with the water, and allow it time to impregnate itself; which is best known by the crust formed on its surface. Filtration indeed is not necessary, if it be not to prevent any undissolved lime being mixed with it; or cruils diminishing its transparency.

The doctor, for his own use, poured about eight pounds of boiling water upon a pound of stone quick-lime in a glazed earthen vessel. He drank about a pint and a half of this lime-water daily for about sixteen months; filling up the vessel, when necessary, with fresh water, sometimes hot and sometimes cold, without observing any difference in the lime-water, which he constantly filtered through grey paper before he drank it. He observed, that the lime was not exhausted after two years and two months, nor was the water sensibly weaker, when it stood a sufficient time on the lime, which he knew by the cruils that were formed. But the lime becoming considerably lighter, after it is long thus used, it at length requires several days to subside, and form the cruils, and after the cruils are formed, it does not leave half the water clear as it did at first. On the whole, this single pound of lime afforded the doctor about six hundred pounds of lime-water. He adds, that having taken lime-water made indifferently of lime-stone, or of chalk, or of shells, and sometimes made of all the three together, he was never able to discover any difference in their effects. But so much lime-water is not to be obtained from quick-lime, unless it be fresh, completely calcined, and free from heterogeneous substances; for if defective in any of these, it will yield proportionally less lime-water. Lewis's Mat. Med. and Jacquer's Chem. Dict.

Mr. Buriel has given an ample account of its effects in the French Memoirs, chiefly from his own experience. But he observes, it succeeded much better in Holland, &c. than in France. It is a powerful alterant, and, like a pure alkaline water, fitted to blunt and destroy acid ferments, which are the principles of all obstructions, and the cause of most chronic diseases. Its principal use is in cachexies, green-sickness, dropsy, scurvy, obstructions on the liver, spleen, &c.

Experience has shewn lime-water to be an excellent medicine in many cases; in the gravel and stone particularly. And it has also been found very serviceable in the gout, in habitual relaxations of the bowels, and in other cases of relaxation. In some kinds of the scurvy likewise it is of use; and is often applied with success externally to ulcers, &c.

Fabricius ab Aquapendente assures us, he cured a scirrhus spleen, and the dropsy, by a continued use of sponges

dipped in common lime-water, and placed near the part affected. Boyle's Works, Abr. vol. i. p. 80.

Lime-water, which was long looked on as a caustic, was, in the last century, found to be a very safe and valuable remedy. It is uncertain who first ventured to give it inwardly, but Willis, Bates, and Moreton, seem to have used it much.

Lime-water kills worms, and many other, if not all, insects. Hence Dr. Alston concludes, it might prove a good anthelmintic for children; and experience has confirmed this notion.

It is probable, that lime-water may be of great use in long sea-voyages, preventing the corruption of water, or insects breeding in it, as well as curing the diseases to which sea-sailing people are most subject. The experiment is certainly safe, easy, and attended with no expense; one pound of fresh well-burnt quick-lime of any kind being enough for a hoghead of water, which may not only be used for common drink by the diseased, or for prevention by the healthy; but also by boiling and exposing it to the air for a short time, it may be reduced to sweet water, and used in dressing the victuals of the most delicate.

The virtues of lime-water do not depend on its absorbency; and it may as justly be called antalkaline, as antacid.

Lime-water prevents, or long protracts, the putrefaction of animal substances. Dr. Alston also thinks that quick-lime in a ship's well would effectually prevent the corruption of the water, and consequently the putrid steams, or foul air, thence arising, which sometimes prove fatal to the crew.

The virtues of lime-water outwardly applied in many diseases of the skin, in excoriations, ulcers, gangrenes, &c. are well known. Perhaps there is not a better gargarism for several sorts of sores in the mouth and throat than lime-water. It has also been known to be of great use in the tooth-ache. Inwardly taken, lime-water has all the virtues of pure element, which are not a few; and on which probably depend the good effects of mineral waters, more than on the minerals they contain. Dr. Alston never found it caused thirst; on the contrary, he found it quenched thirst as well as simple water, and custom rendered it agreeable. Lime-water is notably detergent and attenuating, even more so than soap itself, of mucous, viscid, and other animal fordes, which makes it preferable, in many cases, to the purgals, as well as to mineral waters. In a word, lime-water may be said, in general, to purify the blood, with as good reason, as any other medicine whatever, especially from any putrid, purulent, or scorbutic foulness.

Dr. Lewis observes, that lime-water, drank to the quantity of a quarter of a pint three or four times a day, has been found serviceable in ferofulous complaints, fluxes, seminal weaknesses, and other disorders proceeding from an impurity of the fluids, or laxity and debility of the solids. It generally promotes urine; orientates the cuticular discharge; and, where the stomach is oppressed with viscid phlegm, expectoration. It for the most part binds the belly, and sometimes occasions a troublesome constiveness, unless this effect be occasionally provided against by the interposition of proper laxative. It answers best in cold, sluggish, phlegmatic, and corpulent habits; and is to be used more cautiously in hot, bilious dispositions, and where the patient is much enaciated, or the appetite weak, and at the time of any critical or periodical evacuation. It has been customary to impregnate lime-water with different materials,

nat-rials, partly for rendering it more acceptable to the palate and stomach, and partly for improving its medicinal efficacy against cutaneous defecations. The college of Edinburgh directed, in this view, three ounces of the shavings of the wood and bark of salutaris, one ounce and a half of sliced liquorice, and four drams and a half of bruised nutmegs; the college of London, half an ounce of salutaris bark, and one ounce of liquorice, with the addition, in some cases, of four ounces of rasped guaiacum wood, and three drachms of coriander seeds; to be macerated for four days in three quarts of lime-water, and the liquid strained off for use. These infusions are taken in the same quantities as the simple lime-water, by themselves, or with the addition of milk. Lewis's Mat. Med.

But Dr. Macbride observes, that the activity of lime-water is impaired by infusing vegetable substances therein, which contain much fixed air, such as the guaiacum or salutaris; for these woods, abounding in resin, give out their cementing principle, which, uniting with the dissolved quick lime, restores it to its original state of an inactive calcareous earth: therefore, when it is intended that these woods, or any other substance of the like nature, should give out their virtue to lime-water, and that the water should, at the same time, contain its due proportion of dissolved lime, some quick-lime ought to be added, during the time of maceration. He also observes, that as milk contains a large proportion of fixed air, it ought not to be mixed with lime-water, since it must necessarily take off from its activity. To the same purpose, Dr. Alton has observed, that there is scarcely any thing that is usually mixed and given along with lime-water, that does not, more or less, destroy its efficacy; for which reason he recommended it always to be taken alone. Macbride's Essays, p. 250. 251.

It is observed by Dr. Lewis, that lime-water dissolves, by the assistance of heat, mineral sulphur, vegetable oils and resins, and animal tats. It extracts also, in the cold, the virtues of sundry resinous and oily vegetables, and dissolves thick phlegm, and mucous matters, and the curd of milk, with which last it forms a white liquid, nearly similar to milk in its natural state. But the solvent power of quick-lime has been evinced by Dr. Macbride, and shewn to extend to a variety of different substances, as camphor, myrrh, gum guaiacum, asa fetida, aloes, castor, balsam of Tolu, mallich, jalap, and the cortex Peruvianus, which were found to yield strong solutions and tinctures; and these, he says, are more elegant medicines, and perhaps may be found more efficacious than the spirituous tinctures, since they will never become turbid, or separate on being mixed in any watery vehicle. And since the solvent power of quick-lime is found to depend on its depriving certain substances of that fixed air or carbonic acid, which is their cementing principle, it was natural to imagine that it might be usefully applied to the solution of the human calculus or stone.

Of the various substances examined by Dr. Hales, with a view of determining their respective quantities of fixed air, the human calculus was found to contain the largest proportion; above one-half of this mass consisting of fixed air. Nevertheless, if the caustic alkali, or lime-water, could be safely conveyed to it, these would absorb the fixed air, and the earthy parts, deprived of what bound them together, must presently fall to pieces. That lime-water is lithontriptic has been shewn sufficiently by Dr. Hales, and more fully by Dr. Whytt. See his Essay on the virtues of Lime-water, in the Cure of the Stone, and Edinb. Ess. &c. vol. ii. art. 13. p. 383. vol. v. art. 69.

This gentleman prefers calcined oyster-shell lime-water to any other; which he says, proves a more active menstruum

for this concrete, than that made from the stone limes; the dissolving power of the oyster-shell lime-water seeming, from Dr. Whytt's experiments, to be more than double to that of the stone lime-waters. Dr. Alton seems to think this a matter of indifference; and was himself cured chiefly by the stone quick-lime water before mentioned. This lithontriptic quality of lime-water has been farther confirmed by Dr. Alton, who has shewn the efficacy of lime-water in this respect, not only when made by the first infusion, and assailed by artificial heat, but even after fifty or more infusions, and in the common air. The doctor thinks that the energy of lime-water in this case probably consists in its penetrating detergency, whereby, insinuating itself among the solid parts of the calculi, or into their pores, it separates them, or diminishes their cohesion, but does not dissolve them. See LITHONTRIPTIC.

But the efficacy of quick-lime and caustic alkali in this intention, is now known to depend principally, if not entirely, on its power of absorbing the air, which binds calculous substances together. However, the alkali, when combined with oil, and made into soap, is not only so greatly obtunded thereby, as to lose much of its power, but the soap itself is so nauseous, that few persons can be induced to take it in a quantity sufficient to prove of much effect: it would, therefore, be a happy discovery if any vehicle could be found out that would sheathe the acrimony of the caustic alkali, so as to allow it to be taken in large and continued doses. Possibly, says Dr. Macbride, veal broth, or a decoction of marshmallow roots, might be found to answer this purpose; and lime-water might be taken at the same time, which would not at all interfere with the operation of the alkali, but rather add to its activity. Dr. Chittick's nostrum, which is found, after a perseverance of some months, actually to dissolve the stone, is said to be nothing more than the caustic alkali, given in veal broth. But lime-water, when taken alone, must often fail in producing any considerable effect as a lithontriptic, because it will lose much of its power, as Dr. Macbride has shewn, from the fixed air of the alimentary substances in the first passages, who, therefore, recommends it to be drank when the stomach is empty; and also, as Dr. Whytt and Dr. Macbride have proved by experiments, from the fixed air of the urine itself, which will saturate great part of the quick-lime, even when it hath reached the bladder. Macbride's Essays, ess. 5. passim.

Since there is but a small proportion of lime in the water, it may be thought that taking a few grams of the quick-lime in substance would prove much more effectual in the stone, than large quantities of lime-water. But this is a mistake; and hence Mrs. Stephens's egg-shells and snail-shells, if burnt to quick-lime, can never be equally successful with lime-water for the stone.

As for the *aquez benedicta composita*, or compound lime-waters, they are not to be compared with simple lime-water in the gravel; nor, in Dr. Alton's opinion, in any disease requiring this water.

The doctor adds, in his Appendix, that though he cannot yet determine how far lime-water may be proper, even in acute dysenteries, yet he has found it safe in febrile colds; and by the cases he there mentions, it seems probable that lime-water, by its diluent and diuretic qualities, may prove more useful in fevers than is at present believed.

However this may prove on farther trials, it may be said, in general, that lime-water is diluent, detergent, antiseptic, antispasmodic, diuretic, and vulnerary; useful in all diseases proceeding from, or accompanied with, obstructions in the bowels

bowels or glands, viscid phlegm, calculeous concretions, or putrefaction; and commended for the scurvy, ferophulae, gravel, consumptions, empyema-asthma, arthritis vaga, cedematous swellings, diabetes, fluor albus, fluxes, &c. and outwardly for diseases of the skin, ulcers, gangrenes, &c. It may be taken to the quantity of a pound, once, twice, or thrice a day; or used for common drink. See Dr. Alston's Dissertation on Quick-lime, and Lime-water, Edinb. 1752. See LITHONTRIPTIC.

LIME-Water, in *Gardening*, an useful kind of water, which is prepared by slaking caustic lime in soft water, in the proportion of half a peck of the former to thirty-two gallons of the latter, letting them remain some time before they are made use of, stirring them well, two or three times a day, for two or three days. It is a liquid which, when the lime has subsided, is found highly useful in clearing fruit-trees from the ravages of the Aphis puceron, or vine-fretter. It should be applied once a day by means of an engine, so as to be thrown as much as possible on the under sides of the leaves, and with considerable force, pressing the fore finger upon the end of the pipe, to make it spread like small rain, and taking care that every part of the tree be well watered. It should be done as much as possible in cloudy weather, and when the sun is off the walls. Where the trees have an easterly aspect, they may be watered about half-past eleven o'clock in the forenoon, and in a northern one, the first thing in the morning; but in a southern aspect, about four o'clock in the afternoon. But when northerly or easterly winds and frosty nights prevail, it should be discontinued till the weather becomes mild. The trees should always get dry before night, and never be watered when the sun is upon them. Care must likewise be taken that the grounds of the lime be not made use of, as it would make the trees have a disagreeable appearance, and perhaps be injurious. See PUCERON and VINE-FRETTOR.

LIME-Work, such works or kilns as are constantly employed in the manufacturing of lime. A late writer has thought it necessary, that the managers of estates should understand the nature of this sort of manufacture, though it is seldom necessary or eligible for a large proprietor of land to carry on his own lime-works, "unless during a limited time, at the outset of new works, to ascertain their value," as there are always enterprising men who will give more rent for a work, than the profits arising from it to a proprietor, even when under the direction and management of the most faithful person. They and the lands attached to them should rather be considered by such proprietors as farms, the building of kilns and sheds as erecting farm offices, and the laying out and constructing of roads, railways, &c. as general improvements of their estate; the tenants agreeing to work the quarries agreeable to articles, and to keep the kilns, buildings, and roads in states of proper repair.

LIME, in *Geography*, a town of America, in Grafton county, New Hampshire, situated on the E. bank of Connecticut river; 12 mils S. of Dartmouth college, and containing 1318 inhabitants.

LIMER, LYEMMER, or Lime-hourl. See *Blood-Hound* and *Dog*.

LIMERICK, in *Geography*, a county of Ireland, in the province of Munster, called from the town of the same name, which was, from the earliest times in Irish history, a place of considerable importance. At the time when the Irish chieftains did homage to Henry II. Daniel O'Brien, king of Limerick, was of the number. This prince appears to have been also sovereign of Clare, which was then called Thomond. Limerick is bounded on the north by the

counties of Clare and Tipperary, being separated from the former by the river Shannon, on the west by Kerry, on the south by Cork, and on the east by Tipperary. Its length from east to west is 40 Irish (51 English) miles. Its breadth from north to south 25 Irish (32 English) miles. It contains 386,750 acres, or 604 square miles Irish, equal to 622,975 acres, or 970 square miles English. There are 125 parishes, which by unions form 60 benefices, of which 33 only had parish churches at the time Dr. Beaufort published. The parishes are mostly in the dioceses of Limerick and Emly. The population was stated by Dr. Beaufort at 170,000, but it must have considerably increased. The soil of Limerick is extremely good for tillage, and very productive of grafs; especially those grounds which are called the *coracks*, whose fertility is proverbial, and is caused by the rich manure which is annually deposited by the overflowings of the Shannon. The heaviest and fattest beasts that are slaughtered at Cork are fed in this county; much butter is exported from it; the orchards produce a very fine cyder, and it is by no means destitute of trees and plantations. The pasture system, which has been on the decline in most parts of Ireland since the introduction of corn bounties, proposed by that enlightened friend of his country, the Rt. Hon. John Foster, when chancellor of the exchequer, still continues in Limerick, but is on the decline. Even when Mr. Young wrote in 1778, he observed a great increase of tillage; "thrice the corn grown that there was formerly; much pasturage broken up on this account, some bullock land and some sheep land." The same intelligent writer also speaks of improvement in the state of the poor, but this still wants amelioration. Limerick, though diversified by small hills, is not at all mountainous, except on the south-east, where it is bounded by the Galtees, a ridge of formidable mountains, that extend into Tipperary, and on the borders of Kerry, where it grows uneven, and forms a grand amphitheatre of low but steep mountains, which extends in a wide curve from Loughil to Drumeckolohen. In the first of these rises the river Maig, which crosses the county, and falls into the Shannon; as do many fine streams by which it is plentifully watered. In the western hills are the sources of the Feale and the Gale, which run westward through Kerry, and of the *Black* water which flows in a contrary direction through the county of Cork. Limerick is the county town; for which see the next article. There are no other towns of consequence. A colony of palatines from Germany was settled in this county about a century ago, by a former lord Southwell. Of these Mr. Young mentions some particulars which are interesting. "They have in general leases for three lives, or 31 years, and are not cottars to any farmer, but if they work for them, are paid in money. The quantities of land are small, and some of them have their feeding land in common by agreement. They are different from the Irish in several particulars; they put their potatoes in with the plough in drills, horse-hoe them while growing, and plough them out. One-third of the dung does in this method, for they put it only in the furrows, but the crops are not so large as in the common method. They plough without a driver: a boy of twelve has been known to plough and drive four horses, and some of them have a hepper in the body of their ploughs, which sows the land at the same time it is ploughed. Their course of crops, 1. Potatoes, 2. Wheat, 3. Wheat, 4. Oats; or 1. Potatoes, 2. Barley, 3. Wheat, 4. Oats: in which management they keep their land many years, never laying it out as their neighbours do. They preserve some of their German customs; they sleep between two beds: they appoint a burgomaster, to whom they appeal in case of all disputes; and

and they yet (1778) preserve their language, but that is declining. They are very industrious, and in consequence are much happier, and better fed, clothed, and lodged, than the Irish peasants. We must not however conclude from thence, that all is owing to this; their being independent of other farmers, and having leases, are circumstances which will create industry. Their crops are much better than those of their neighbours. There are three villages of them, about 70 families in all. For some time after they settled, they fed upon four crout, but by degrees left it oil, and took to potatoes; but now subsist upon them and butter and milk, but with a great deal of oat bread, and some of wheat, some meat and fowls, of which they raise many. They have all offices to their houses, that is, stables and cow-houses, and a lodge for their ploughs, &c. They keep their cows in the house in winter, feeding them upon hay and oat straw. They are remarkable for the goodness and cleanliness of their houses. The women are very industrious, reap the corn, plough the ground sometimes, and do whatever work may be going on; they also spin, and make their children do the same." The late Silver Oliver, esq. of Castle Oliver, planted another colony, taken from this first, of about 66 families, amounting to 700 Protestants, on his estate, and of these Mr. Young gives a similar account. But with these exceptions, the husbandry of the county of Limerick is perhaps the worst in Munster, which is attributed to the natural richness of the soil, and to the greater prevalence of the grazing system. Mr. Young says, that the rich land reaches from Charleville, at the foot of the mountains, to Tipperary by Kilsenning, a line of 25 miles, and across from Ardpetuch to within four miles of Limerick 16 miles. Bruff, Kilmallock, and Hospital have very good land about them; the quantity in the whole conjectured to be 100,000 acres. This is chiefly under bullocks. The corseilles on the Shannon are from two to three miles broad. There is also a light lime-stone land, for sheep and cows. Mr. Young, speaking of the land near Castle Oliver, in the rich district, says, "it is a rich, mellow, crumbling, putrid, sandy loam, 18 inches to three feet deep, the colour a reddish-brown. It is dry sound land, and would do for turnips exceedingly well, for carrots, for cabbages, in a word for every thing. I think, upon the whole, it is the richest soil I ever saw, and such as is applicable to every purpose you can wish; it will fat the largest bullock, and at the same time do equally well for sheep, for tillage, for turnips, for wheat, for beans, and in a word for every crop and circumstance of profitable husbandry." After some other particulars he concludes thus: "The face of the country is that of desolation; the grounds are over-run with thistles, ragwort, &c. to excess; the fences are mounds of earth, full of gaps; there is no wood, and the general countenance is such that you must examine into the soil before you will believe that a country, which has so beggarly an appearance, can be so rich and fertile." These remarks were written above 30 years ago, and improvement has since taken place, but they are still too applicable. Limerick is represented in the imperial parliament by three members, two for the county, and one for the city. This county has not yet had a statistical account of it published. Beaufort, Young.

LIMERICK, a city of Ireland, capital of the county of the same name, strongly situated on the river Shannon, on an island in which it is partly built. It is a port-town, and is represented in parliament. The new port, which is connected with the old city by a bridge, is called Newtown Pery, from the Pery family, the head of which is now earl of Limerick, whose estate it is. The buildings are of brick, large, and uniform, so that whilst the old

town has a very ruinous appearance, this port will bear comparison with the best streets in almost any other city, except where public buildings contribute to ornament them. The public buildings are not many, or deserving of much notice. The custom-house is a plain building. The cathedral is an ancient and venerable pile. The bishop's palace is a comfortable modern house at the well end of the city. The corporation of Limerick is what may be called a close one, as no person can become a freeman, except by favour of the council; freeholders, however, can vote at the election of members of parliament. The magistrates are a mayor, two sheriffs, a recorder, a town- clerk, aldermen and burgesses; it hath also a military governor, constable and town major, and is the residence of the general commanding a district. The population probably exceeds 50,000. The trade of Limerick is very extensive, and is rapidly increasing. Its export of corn is perhaps the greatest in Ireland, and its corn-market is very convenient. It must more and more derive benefit from the canal connecting the Shannon with the Liffey. There are six churches, a Presbyterian meeting-house, a Methodist meeting-house, a Quakers' meeting-house, and several chapels for Roman Catholics, who form the greatest part of the population. There are also some charitable institutions well attended to, and a public library, lately instituted. The inhabitants are reckoned gay and fond of society, and public amusements are in general well supported. Limerick, being naturally a city of strength, and formerly well fortified by art, has always been deemed a place of considerable importance. In 1651 it was taken by Ireton, in the service of the parliament, after a vigorous siege. In 1690, it was unsuccessfully besieged by king William in person. In 1691, it surrendered to general Ginkle, afterwards earl of Athlone, on terms of capitulation very advantageous to the besieged, and all who professed the Roman Catholic religion, which are called the *articles of Limerick*. Limerick is 94 Irish miles S.W. from Dublin. Beaufort, Young, Carlisle.

LIMERICK, a bishopric of Ireland, in the ecclesiastical province of Cashel, united to the bishoprics of Ardferret and Aghadoo, in the year 1663. The two latter have been long incorporated so as to form but one diocese; the dignity of archdeacon, and the ruined walls of a church with a round tower, are all the memorials of the bishopric of Aghadoo that now remain. The whole union comprehends great part of the county of Limerick, the whole of Kerry, and a few parishes in the counties of Cork and Clare. There are in all 176 parishes, which are united so as to form 88 benefices, and of these only 47 have churches, and 14 glebe houses. It is to be remembered, however, that the population is not Protestant. Beaufort.

LIMERICK, a port-town of America, in York county and state of Maine, near the confluence of Oolippe river with Saco, and opposite to Gorham; incorporated in 1787, and containing 905 inhabitants.—Also, a township in Montgomery county, Pennsylvania, containing 999 inhabitants.

LIMPSOL, LIMASSOL, or LIMISSO, a town of the island of Cyprus, formerly *Nemofia*, is now in a miserable state, abounding with ruins and rubbish. Its harbour, however, is not a little frequented; here vessels are loaded with grain, cotton, and other productions of the soil. The best Cyprus wines are made in its environs, and it is the emporium of all those of the island who are concerned in trade. Not far from this town, if it deserves that appellation, stood the ancient "Limassol," which still, at a period of remoter antiquity, was called *Amathus*, celebrated for a temple consecrated to Venus and Adonis, in which was preserved,

preserved, according to Pausanias, a rich necklace of precious stones, ornamented with gold, the work of Vulcan, and given in the first instance to Hermione. But this ancient town is destroyed. (See AMATHUS.) Near Limassol, E. of it, is the most southern promontory of the island, formerly named the promontory of *Agathiri*, at present Cape di Gatti or *Gatto*, on account of the great number of cats kept by the monks, who, in the 4th century, obtained permission to establish themselves there, as well as on mount Olympus, on condition of keeping many of those animals for hunting and destroying snakes, which had multiplied in the island. (See CATTO and CYPRUS.) Limassol is the see of a bishop, suffragan of Nicotia. N. lat. 34° 45'. E. long. 32° 30'.

LIMESTONE, a post-town of America, in Kentucky, on the S. side of Ohio river, and on the W. side of a small creek of the same name. This is the usual landing place for people who come down in boats with an intention of settling in the upper parts of the state, and here the champagne country on the E. side of the river begins; four miles N.E. of Washington. N. lat. 38° 40'. W. long. 84° 17'.

LIMETREE, in *Gardening*, is a tree of the deciduous kind, occasionally used in plantations for its wood, &c. There are four species, each of which is capable of being raised from layers and cuttings.

It is suggested by Mr. Nicol, that this sort of tree succeeds in the most perfect manner, in "low, deep, sub-humid booms," but that "in dry gravelly soils, it loses the beautiful gloss of its foliage, for which it is so much admired in the early summer season."

It may be noticed that the timber of the limetree is used by carvers, it being a soft light wood; as also by architects for framing the models of their buildings, &c. The turners likewise use it for making light bowls, dishes, &c. but it is too soft for any strong purposes. See CUTTINGS, in *Botany*, *Gardening*, and *Painting*. See also TULIN.

LIMETREE BAY, in *Geography*, a bay on the S. coast of Santa Cruz. N. lat. 27° 45'. W. long. 63° 27'.

LIMETUM, in *Botany*, appears from Pliny to be a name of Gallic origin for a plant with which the ancient Gauls poisoned their arrows. This appellation, however, could not have been originally applied to the present genus, all the species of which are natives of the Cape of Good Hope. Linn. Gen. 182. Schreb. 246. Willd. Sp. Pl. v. 2. 201. Mart. Mill. Dict. v. 3. Art. Hort. Kew. ed. 2. 337. Juss. 314. Lamarck Illustr. t. 275. Gertn. t. 79. —Class a 1 order, *Hyptanthia Digyna*. Nat. Ord. *Urticaceae*, Linn. *Urticaceae*, Juss.

Gen. Ch. Cal. P. distinct inferior, permanent, of five, ovate, acuminate, carinate leaves, membranaceous at the margin, two of them exterior. Cor. Petals five, equal, ovate, with a slight claw, obtuse, shorter than the calyx; recurv forming a margin round the germen, bearing the anthers. Stam. Filaments seven, awl-shaped, shorter than the corolla; anthers ovate. Pist. Germen inferior, globose. Style clavate, cylindrical, shorter than the stamens; stigma rather obtuse. Peric. Capsule globose, of two cells. Seeds foliary, hemispherical, hollow.

Or. We are induced to follow the opinion of Linnæus respecting the capsule of this genus, as it undoubtedly belongs to the *Portulacæ* of Jussieu. See CROCEAE and Schreb.

Ess. Ch. Calyx of five leaves. Pet. five, equal. Capsule globose, of two cells. Seeds foliary, clavate.

1. *L. africanum*. Linn. Sp. Pl. 288. Thunb. Prod. 68. —Leaves oblong, on footstalks. —A native of the Cape,

whence it was brought by Mr. Francis Masson into the Royal Garden at Kew in the year 1774. It flowers in June and July. Linnæus justly remarks, that this tree has the appearance of *Corrigiola* or *Telyllium*. "The root is perennial. Stems prostrate, feeble, a span long, a cubit thick, perennial at the base. Leaves alternate, remote, linear-lanceolate, or oblong, about an inch in length. Corymbs of green and white flowers terminal, foliary, compound, naked, on long stalks. Martyn says that the leaves of this are subject to vary; for that in the Bankian herbarium may be seen linear, oblong, ovate, roundish and spatulate leaves, if the specimens be all of one species."

2. *L. capense*. Willd. v. 2. Thunb. Prod. 68. (Linnæum; Mart. Mill. Dict. v. 3. *L. aphyllum*; Linn. Suppl. 214.) —Leaves ovate, sessile. —It is curious that the younger Linnæus should have given this the specific name of *aphyllum*, remarking that it appears to be without leaves, when at the same time he describes them as ovate and sessile. Martyn, judging from Masson's figure in the Bankian herbarium, says that *L. capense* is a small plant, extremely woody at the bottom. Leaves ovate, about sessile, and as woolly as those of mullein; radical ones numerous; stem-leaves fewer.

3. *L. athiopium*. Willd. and Thunb. —Leaves linear-lanceolate. This species is only known from a description by Thunberg and adopted by Willd. now a delusion. The last author justly observes, that we have a delusion in instance, in these three species of *Limnan* of two forms which are not given for the sake of true distinction; all the plants being natives of the Cape, though severally called *africanum*, *capense*, and *athiopium*.

We further learn from professor Martyn, that there is a fourth species in the Bankian herbarium, which is truly a shrub, and may be called *L. fruticosum*.

LIMINGO, in *Geography*, a town of Sweden, in the government of Uleå; 11 miles S. of Uleå.

LIMINGTON, a town of America, in York county, and state of Maine, bounded N. and E. by Saco river; 50 miles N. of York.

LIMIT, in *Mathematics*. See LIMITS.

LIMIT of distant vision, in *Optics*. See DISTANCE VISION.

LIMITATION, **LIMITATION**, in *Logic*, is a certain time assigned by nature, within which an action must be brought; and limitation of time is twofold; *viz.* to make title to an inheritance by the common law; and in writs by several statutes. There is a limitation in real and personal actions; and in the former, he that will sue for any lands or hereditaments, ought to prove, that he or his ancestors were seized of the lands sued for by writ of assize, or he cannot maintain his action; and this is called limitation of assize. Stat. West. 1. See WRIT OF RIGHT and STATUTE of LIMITATION *infra*. Also INFORMATION.

There is no limitation with regard to the time within which any actions touching personal estate may be brought; so that I have never seen the times of Richard I. and Henry III.; for by that time the Statute of limitation, 22 Hen. VIII. c. 5. had taken place, and extended to any writ of right of any tenement, *freehold*, or estate of *duration*, *hereditament*, or *leasehold*. And thus, perhaps Elfrida, upon very good reason, because it may very easily happen, that the title to an advowson may not come into question, nor the right have an opportunity of being tried, within 60 years, which is the longest period of limitation assigned by the statute of Henry VIII. See ADVOWSON and INCURSION.

Limitation of time. See ENTRY.

Limitation of time, in a legal sense, imports how long

the estate shall continue, or is rather a qualification of a precedent estate. As where one doth give lands to a man to hold to him and his heirs male, and to him and the heirs female, &c. here the daughters shall not have any thing in it, so long as there is a male; for the estate to the heirs male is first limited. Co. Litt. 313.

A limitation is denominated by Littleton (§ 380. 1 Inst. 234.) a "condition in law." For where an estate is so expressly confined and limited by the words of its creation, that it cannot endure for any longer time than till the contingency happens, upon which the estate is to fail, this is denominated a "limitation;" as when land is granted to a man, *so long* as he is parson of Dale, or while he continues unmarried, or *until* out of the rent and profits he shall have made 50*l.* and the like. (10 Rep. 41.) In such case the estate determines as soon as the contingency happens, and the next subsequent estate, which depends upon such determination, becomes immediately vested without any act to be done by him who is next in expectancy. But when an estate is, strictly speaking, upon "condition in deed," (as if granted expressly *upon condition* to be void upon the payment of 40*l.* by the grantor, or *so that* the grantee continues unmarried, or *provided* he goes to York, &c. Rep. 41.) the law permits it to endure beyond the time when such contingency happens, unless the grantor, or his heirs or assigns, take advantage of the breach of the condition, and make either an entry or a claim, in order to avoid the estate. (Litt. § 347. Stat. 32 Hen. VIII. c. 24.) Yet though strict words of condition be used in the creation of the estate, if on breach of the condition the estate be limited over to a third person, and does not immediately revert to the grantor or his representatives, (as if an estate be granted by A to B, on condition that within two years B intermarry with C, and on failure thereof then to D and his heirs,) this the law construes to be a limitation and not a condition (1 Vent. 202.); because, if it were a condition, then upon the breach thereof, only A or his representatives could avoid the estate by entry, and so D's remainder might be defeated by their neglecting to enter; but, when it is a limitation, the estate of B determines, and that of D commences, and he may enter on the lands the instant that the failure happens. So also, if a man by his will devises land to his heir at law, on condition that he pays a sum of money, and for non-payment devises it over, this shall be considered as a limitation; otherwise, no advantage could be taken of the non-payment, for none but the heir himself could have entered for a breach of condition. Cro. Eliz. 201. 1 Roll. Abr. 411. Blackst. Com. b. ii.

LIMITATION of the Crown. The statutes 1 W. & M. cap. 8. 12 W. III. cap. 2. and 1 & 2 Ann. cap. 17. 4 Ann. cap. 8. &c. are acts for the limitation of the crown, and settling it on Protestant heirs in the house of Hanover. See CROWN.

LIMITATION, Statutes of, a species of plea in bar, in which a person may plead the time limited by certain acts of parliament, beyond which no plaintiff can lay his cause of action. This, by the statute of 32 Hen. VIII. c. 2. in a writ of right is *sixty* years; in assises, writs of entry, or other possessory actions real, of the seisin of one's ancestors, in lands; and either of their seisin, or one's own, in rents, suits, and services, *fifty* years; and in actions real for lands grounded upon one's own seisin or possession, such possession must have been within *thirty* years. By stat. 1 Mar. II. c. 5. this limitation does not extend to any suit for advowsons. (See above.) But by the statute 21 Jac. I. c. 2. a time of limitation was extended to the case of the

king, *viz.* *sixty* years precedent to 19th February, 1623. (3 Inst. 183.) but this becoming ineffectual by efflux of time, the same date of limitation was fixed by statute 9 Geo. III. c. 16 to commence, and be reckoned backwards, from the time of beginning any suit, or other process, to recover the thing in question; so that a possession for *sixty* years is now a bar even against the prerogative, in derogation of the ancient maxim "*nullum tempus occurrit regi.*" By another statute, 21 Jac. I. c. 16, *twenty* years are the time of limitation in any writ of formedon; and by consequence, *twenty* years are also the limitation in every action of ejectment; for no ejectment can be brought, unless where the lessor of the plaintiff is entitled to enter on the lands; and by the statute 21 Jac. I. c. 16. no entry can be made by any man, unless within *twenty* years after his right shall accrue. Also, all actions of trespass (*quare clausum fregit*, or otherwise) detinue, trover, replevin, account, and sale, (except upon accounts between merchants), debt on simple contract, or for arrears of rent, are limited by the statute last-mentioned to *six* years, after the cause of action commenced; and actions of assault, menace, battery, mayhem, and imprisonment, must be brought within *four* years, and actions for words within *two* years after the injury committed. And by the statute 31 Eliz. c. 5. all suits, indictments, and informations, upon any penal statutes, where any forfeiture is to the crown alone, shall be sued within *two* years, and where the forfeiture is to a subject, or to the crown and a subject, within *one* year after the offence committed; unless where any other time is specially limited by the statute. Lastly, by statute 10 W. III. c. 14, no writ of error, *scire facias*, or other suit, shall be brought to reverse any judgment, fine, or recovery for error, unless it be prosecuted within *twenty* years. The use of these statutes of limitation is to preserve the peace of the kingdom, and to prevent those innumerable perjuries which might ensue, if a man were allowed to bring an action for any injury committed at any distance of time. Upon both these accounts the law therefore holds, that "*interest reipublice ut sit finis litium,*" and upon the same principle the Athenian laws in general prohibited all actions, where the injury was committed *five* years before the complaint was made. If, therefore, in any suit, the injury or cause of action happened earlier than the period expressly limited by law, the defendant may plead the statutes of limitations in bar; as upon an *assumpsit*, or promise to pay money to the plaintiff, the defendant may plead *non assumpsit infra sex annos*; he made no such promise within *six* years; which is an effectual bar to the complaint. Blackst. Com. b. iii.

LIMITED FEES, denote such estates of inheritance as are clogged or confined with conditions, or qualifications of any sort. These are of two sorts, *viz.* *qualified* or *base-fees*, and *fee-conditional*, or *fee-tail*. See *BASE-FEES*, and *FEES-TAIL*.

LIMITED Problem, is that which admits but of one solution, or which can only be solved one way: as to make a circle pass through three points given, not lying in a right line, to describe an equilateral triangle on a line given, &c. See **PROBLEM**, and **DETERMINATE**.

LIMITROPHOUS COLUMN. See **COLUMN**.

LIMITS, in *Mathematics*, a term sometimes used, in general, for quantities, one of which is greater, and the other less than another quantity. Thus, in the quantities, *a, x, b*, if *a* be less than *x*, and *b* be greater than *x*, *a* and *b* are said to be limits of *x*. The word occurs in this sense, when we speak of the limits of the roots of equations.

Sometimes a quantity is said to be a limit between two others, when it is greater than the one and less than the other. So a ratio is said to be a limit between two other ratios,

ratios, when it is greater than the one, and less than the other.

But limit is often used in a more restricted sense; thus, when a variable quantity approaches continually to some determinate quantity, and may come nearer to it than to have any given difference, but can never go beyond it; then is the determinate quantity said to be the limit of the variable quantity.

Hence, the circle may be said to be the limit of its circumscribed and inscribed polygons; because these, by increasing the number of their sides, can be made to differ from the circle less than by any space that can be proposed, how small soever.

The limit of a variable ratio, is some determinate ratio, to which the variable ratio may continually approach, and come nearer to it than to have any given difference, but can never go beyond it. Hence, the ratio of the ordinate to the sub-tangent of a curve, is said to be the limit of the variable ratio of the differences of the ordinates, to the differences of the abscissæ.

The word limit, in this sense, signifies the same as what sir Isaac Newton calls a first or prime, and a last or ultimate ratio.

There are two cases of a variable quantity, or variable ratio, tending to such a limit, as we have been describing. In the first case, the variable quantity, or ratio, will not only approach to its limit within less than any given difference, but will actually arrive at its limit.

In the second case, the variable quantity, or ratio, will only approach its limit within less than any given difference, but will never actually arrive at it.

Sir Isaac Newton, to avoid the harshness of the hypothesis of indivisibles, and the tediousness of demonstrations, according to the method of the ancients, by deductions *ad absurdum*, has premised several lemmata, in the first section of the first book of his Principles, relating to the first and last sums, and ratios of nascent and evanescent quantities; that is, to the limits of sums and ratios. This doctrine chiefly depends on the first of those lemmata; the words of which are, "Quantitates ut & quantitatuum rationes, quæ ad æqualitatem tempore quovis finito constanter tendunt, & ante finem temporis illius propius ad invicem accedunt quam pro data quavis differentia, sunt ultimo æquales."

The learned gentlemen, who have written in defence of sir Isaac, against the author of the Analyst, are not agreed among themselves as to the precise meaning of this lemma. One of these gentlemen says, that the genuine meaning of this proposition is, that those quantities are to be esteemed ultimately equal, and those ratios ultimately the same, which are perpetually to each other, in such a manner, that any difference, how minute soever, being given, a finite time may be assigned, before the end of which, the difference of those quantities, or ratios, shall become less than that given difference. See Pref. State of the Rep. of Letters for Oct. 1735, and for Oct. 1736.

What sir Isaac Newton intends we should understand by the ultimate equality of magnitudes, and the ultimate identity of the ratios proposed in this lemma, will be best known from the demonstration annexed to it. By that it appears, sir Isaac Newton did not mean that any point of time was assignable, wherein these varying magnitudes would become actually equal, or the ratios really the same; but only that no difference whatever could be named, which they should not pass. The ordinate of any diameter of an hyperbola, is always less than the same continued to the asymptote; yet the demonstration of this lemma can be applied, without changing a single word, to prove their ultimate equality.

The same is evident from the lemma immediately following, where parallelograms are inscribed, and others circumscribed to a curvilinear space. Here the first lemma is applied to prove, that by multiplying the number, and diminishing the breadth of these parallelograms *in infinitum*, that is, perpetually and without end, the inscribed and circumscribed figures become ultimately equal to the curvilinear space, and to each other; whereas, it is evident, that no point of time can be assigned, wherein they are actually equal; to suppose this were to assert, that the variation ascribed to the figures, though endless, could be brought to a period, and be perfectly accomplished; and thus we should return to the unintelligible language of indivisibles. The excellence of this method consists in making the same advantage of this endless approximation towards equality, as by the use of indivisibles, without being involved in the absurdities of that doctrine. In short, the difference between these two may be thus explained.

There are but three ways in nature of comparing spaces: one is by shewing them to consist of such, as by imposition on each other will appear to occupy the same place: another is, by shewing their proportion to some third; and this method can only be directly applied to the like spaces as the former; for this proportion must be finally determined by shewing when the multiples of such spaces are equal, and when they differ: the third method to be used, where these other two fail, is by describing upon the spaces in question such figures as may be compared by the former methods; and thence deducing the relation between those spaces, by that indirect manner of proof, commonly called *ductio ad absurdum*; and this is as conclusive a demonstration as any other, it being indubitable, that those things are equal which have no difference. Thus Euclid and Archimedes demonstrate all they have written concerning the comparison and mensuration of curvilinear spaces. The method advanced by sir Isaac Newton for the same purpose differs from their's, only by applying this indirect form of proof to some general propositions, and from thence deducing the rest by a direct form of reasoning. Whoever compares the fourth of sir Isaac Newton's lemmas with the first, will see, that the proof of the curvilinear spaces, there considered, having the proportion named, depends wholly upon this, that if otherwise the figure inscribed within one of them, could not approach, by some certain distance, to the magnitude of that space: and this is precisely the form of reasoning, whereby Euclid proves the proportion between the different circles. As this method of reasoning is very diffusively set out in the writings of the ancients; and sir Isaac Newton has here expressed himself with that brevity, that the turn of his argument may possibly escape the unwary, the reading of the ancients must be the best introduction to the knowledge of his method. The impossible attempt of comparing curvilinear spaces, without having any recourse to the forementioned indirect method of arguing, produced the absurdity of indivisibles.

As the magnitudes, called in this lemma ultimately equal, may never absolutely exist under that equality; so the varying magnitudes holding to each other the variable ratios, here considered, may never exist under that, which is here called the ultimate ratio. Of this sir Isaac Newton gives an instance, from lines increasing together by equal additions, and having from the first a given difference. For the ultimate ratio of these lines, in the sense of this lemma, as sir Isaac Newton himself observes, will be the ratio of equality, though these lines can never have this ratio; since no point of time can be assigned, when one does not exceed the other.

In like manner, the quantities called by sir Isaac Newton vanishing, may never subsist under that proportion here esteemed their ultimate.

In the case of drawing tangents to curves, where the ordinate bears the same proportion to the subtangent, as that wherewith the difference of the ordinates, to the difference of the abscissæ, vanish; these lines must not be conceived, by the name of an evanescent, or any other appellation, ever to subsist under that proportion: for should we conceive these lines, in any manner, to subsist under this proportion, though at the instant of their vanishing, we shall fall into the unintelligible notion of indivisibles, by endeavouring to represent, to the imagination, some inconceivable kind of existence of these lines between their having a real magnitude, and becoming absolutely nothing. Sir Isaac Newton was himself apprehensive, that this mistake might be made; for as he thought fit (in compliance with the bad taste which then prevailed) to continue the use of some loose and indistinct expressions resembling those of indivisibles, for which he has himself apologized, he expressly cautions us against misinterpreting him in this manner, when he says: "Si quando dixerō quantitates quā minimas vel evanescentes, vel ultimas, cave intelligas quantitates magnitudinis determinatas, sed cogita semper diminuendas sine limite." Thus expressly has he declared to us, that vanishing quantities, or whatever other less accurate appellation he names them by, are to be considered as indeterminate quantities bearing to each other, under their different magnitudes, different proportions; which the quantities themselves can never obtain, and the limit of these proportions is that, for the sake of which these quantities are considered: inasmuch, that since these quantities have different proportions, while they obtain the name of vanishing quantities, the term ultimate is necessarily added to denote that proportion, which is the limit of an endless number of varying ones. The like remark is necessary, when these quantities are considered in the other light, as arising before the imagination: for then the proportion intended must be specified, by calling it the first, or prime proportion of these quantities. And as this additional epithet is necessary to express the proportion intended, so it is absurd to apply it to the quantities themselves; as sir Isaac Newton says, there are "rationes primæ quantitatum nascentium," but not "quantitates primæ nascentes." *Philosoph Transactions*, N 342, p. 205.

So that, according to the author we have been quoting, all the examples given by sir Isaac in the before mentioned section, are to be understood of such limits or ultimate ratios, as are never attained to by the quantities and ratios limited, but to which these may approach indefinitely, that is, so as to differ less than by a given quantity.

On the other hand, a learned gentleman, who assumed the name of Philalethes Cantabrigiænsis, thinks that sir Isaac means, by the words of the lemma, and proves, in his demonstration, not that the quantities or ratios are barely to be considered as ultimately becoming equal, or are to be esteemed as ultimately equal; though, in reality, they can never have that proportion to each other; but that they do at last become actually, perfectly, and absolutely equal. *Pres. State of the Republic of Letters for November 1735*, p. 371.

He also distinguishes, as above, between quantities and ratios which arrive at their limits, and those which do not. And it is insisted on, that every one of the examples given in the lemmata of this first section of the first book of sir Isaac's Principles, are of such quantities and ratios as actually arrive at their respective limits; nor is there an in-

stance there given of a quantity, or ratio, which never arrives at its limit, except one at the latter end of the scholium of this section (and that by way of illustration of a particular objection only) of two quantities, having a given difference, and being equally increased, *ad infinitum*, and whose ratio, it is admitted, never arrives at its limit. But decreasing quantities may really and in fact be diminished *ad infinitum*: for they may vanish and come to nothing. The ratio, therefore, of these, says he, may arrive at its limit; though that of the others cannot.

Neither are these learned gentlemen agreed as to the sense of the word *vanishing* or *evanescent*, in the scholium of this first section of sir Isaac's Principles.

The question is, whether the quantities that vanish are understood to spend some finite time in vanishing, or to vanish in an instant, or point of time; and consequently, whether they bear one to another an infinite number of different successive ratios during the vanishing, or one ratio only, at the point or instance of their evanescence.

This last is the sense in which Philalethes takes the word *evanescent*, or *vanishing*; and the dispute, on this head, as he observes, is of no other consequence than to determine, whether the sense in which he uses the word be agreeable to sir Isaac Newton's. For, if the quantities vanish in an instant, I take the only ratio with which they vanish; or they spend a finite time in vanishing, and I take the last of the ratios, which they successively bear to one another during that time; still the ratio, taken in either of these cases, will be one and the same. *Present State of the Republic of Letters for November 1735*, p. 383, 384.

We cannot pretend to give the whole detail of this controversy, but must refer the curious to the *Present State of the Republic of Letters for 1735*. We shall only observe, that this disquisition is partly critical and partly scientific. The critical inquiry is into the sense of sir Isaac, so far as it may be determined from his own words; and here we cannot help thinking that this is somewhat doubtful. The other inquiry is about the true or scientific notion, upon which this doctrine ought to be founded. With respect to which we shall only ask two questions, which every reader may resolve for himself, to wit, whether the conception or notion he has of the ratio or proportion of evanescent quantities, at the point or instance of their evanescence, be more clear and distinct than the notion of infinitesimals? And whether the notion of inscribed or circumscribed polygons to any curve, attaining their last form, and thereby coinciding with their curvilinear limit, be more clear and distinct than the notion of polygons of an infinite number of sides in the method of infinitesimals?

Before we leave this subject, it may be proper to give the sentiments of an eminent mathematician about the doctrine of limits, or of prime and ultimate ratios, and to shew the connection of this doctrine with that of fluxions. Mr. Maclaurin, in his *Treat. of Flux.*, art. 502.

Sir Isaac Newton considers the simultaneous increments of flowing quantities as finite, and then investigates the ratio which is the limit of the various proportions which those increments bear to each other, while he supposes them to decrease together till they vanish; which ratio is the same with the ratio of the fluxions. In order to discover this limit, he first determines the ratio of the increments in general, and reduces it to the most simple terms, so as that (generally speaking) a part at least of each term may be independent of the value of the increments themselves; then, by supposing the increments to decrease, till they vanish, the limit readily appears.

For example, let a be an invariable quantity, x a flowing quantity,

quantity, and any increment of x : then the simultaneous increments of xx and ax will be $2xo + oo$ and ao , which are in the same ratio to each other as $2x + o$ is to a . This ratio of $2x + o$ to a continually decreases while o decreases, and is always greater than the ratio of $2x$ to a , while o is any real increment; but it is manifest, that it continually approaches to the ratio of $2x$ to a as its limit; whence it follows, that the fluxion of xx is to the fluxion of ax , as $2x$ is to a . If x be supposed to flow uniformly, ax will likewise flow uniformly, but xx with a motion continually accelerated; the motion with which ax flows, may be measured by ao ; but the motion with which $2x$ flows is not to be measured by its increment $2xo + oo$, but by the part $2xo$ only, which is generated in consequence of that motion; and the part oo is to be rejected, because it is generated in consequence only of the acceleration of the motion with which the variable square flows, while o , the increment of its side, is generated; and the ratio of $2xo$ to ao is that of $2x$ to a , which was found to be the limit of the ratio of the increment $2xo + oo$ and ao . See FLUXION.

It is objected against sir Isaac Newton's method of investigating this limit, that he first supposes that there are increments; that when it is said *let the increment vanish*, the former supposition is destroyed, and yet a consequence of this supposition, *i. e.* an expression got by virtue thereof, is retained. But the suppositions that are made in this method of investigating the limit are not so contradictory as this objection seems to import. He first supposes that there are increments generated, and represents their ratios by that of two quantities, one of which is given so as not to vary with the increments. If he had afterwards supposed that no increments had been generated, this indeed had been a supposition directly contradictory to the former. But when he supposes those increments to be diminished till they vanish, this supposition surely cannot be said to be so contradictory to the former as to hinder us from knowing what was the ratio of those increments, at any term of the time, while they had a real existence; how this ratio varied, and to what limit it approached while the increments were continually diminished: on the contrary, this is a very concise and just method of discovering the limit which is required.

It is to be observed, that the limiting, prime, or ultimate ratio of increments, strictly speaking, is not the ratio of any real increments whatsoever. But as the tangent of an arch is the right line that limits the position of all the secants that can pass through the point of contact, though, strictly speaking, it be no secant; so a ratio may limit the variable ratios of the increments, though it cannot be said to be the ratio of any real increments. The ratio of the generating motion may be likewise said to be the last or ultimate ratio of the increments, while they are supposed to be diminished till they vanish, for a like reason. It may just be added, that there being two cases of variable quantities and ratios tending to a limit, it might have conducted to perspicuity, and preventing disputes, to have distinguished these different limits by some addition. As in the first case to have called it a limit or ultimate ratio *inclusive*; because the limit is the last of the quantities or ratios limited: and in the second to have called it a limit or ultimate ratio *exclusive*; because the quantities limited never attain to the limit, though they approach to it indefinitely.

This distinction may perhaps receive some farther illustration from the following example. It is known that the osculatory circle is a circle that touches a curve so closely that no other circle can be drawn through the point of contact between them, all other circles passing within or with-

out them both; and hence the osculatory circle is supposed to have an equal curvature with the curve at that point. See Mr. Maclaurin's Flux. art. 394.

Now if we conceive the osculatory circle at the end of the great axis of an ellipsis, it will fall entirely within the ellipsis; and the curvature of the ellipsis and osculatory circle may both be said to be limits of the curvatures of all the circles falling wholly within, and touching the ellipsis at the end of its great axis. But the term limit will not in both cases have precisely the same meaning; for the osculatory circle is a limit *inclusive*, being the last of the circles limited; and the ellipsis is a limit *exclusive*, none of the circles limited ever coinciding with it. As to the circles which fall wholly without the ellipsis, and touch it at the end of its great axis, they have no limit *inclusive*, no circle touching the ellipsis so closely, that no other can pass between; the only limit here is *exclusive*, the ellipsis itself.

The contrary of this happens at the end of the lesser axis. At any other point of the ellipsis, one half of every osculatory circle is a limit *inclusive* of the femicircles that fall within, and the other half is a limit *exclusive* of those that fall without.

May we not ask, if a curve is the limit of its inscribed or circumscribed polygons in any other sense, than the curvature of the ellipsis is the limit of the curvatures of the circles before described, which approach nearer and nearer to the curve, but never coincide with it? It is true we hear it often said, that the osculatory circle is equicrural, and so coincides with the ellipsis; but this seems a consequence of the language of infinitesimals. It would be more accurate to say, that the curvature of the ellipsis is the limit *exclusive* of all the before mentioned circles, and that the osculatory circle is their limit *inclusive*. That excellent geometer, Mr. Simfon, in his Conic Sections, lib. v. prop. 36. cor. says only, after demonstrating the chief property of the osculatory circle, that *eandem habere cum sectione conica curvaturam dicitur*, giving this only as an appellation, but not as a proposition. See on the subject of this article, Robins's Disc. on Fluxions, in his Tracts, vol. ii.

LIMITS of the Roots of an Equation.—We have already observed, that by finding the limits of the roots of an equation, is to be understood the finding of two such numbers, that one shall be greater and one less than the root required; by which means an approximation is evidently made towards the true root, and the nearer these limits approach towards each other, so much the more accurate will be the approximation. La Grange, in his "Traité de la Résolution numérique des Equations," has carried the method of limits to its utmost possible perfection, by shewing, in all equations, how the limits of each of its roots may be ascertained, and has shewn, that the method of approximation employed by Newton, and in fact every method, except that of his own, is defective in this respect, *viz.* that between the limits ascertained in their operation, there may be one, two, or more roots, and consequently, that they are not necessarily the limits of one root, but merely the limits between which one at least of the real roots of the equation must lie. The nature of this article will not admit of our entering into an explanation of the process of this celebrated analyst; we can, therefore, only refer the reader to the work itself, and must content ourselves in this place with giving a few of the most remarkable cases relating to the limits of the roots of an equation.

1. If we can find two quantities, which, being substituted for the unknown quantity in any equation, give two results with contrary signs, then will these two quantities

be the limits of the value of x , that is, a value of x will always be found between these two quantities.

Let $x^m = Ax^{m-1} + Bx^{m-2} - Cx^{m-3} + \&c. + N = 0$; and suppose that, by substituting any quantity p , instead of x , we have

$$p^m - Ap^{m-1} + Bp^{m-2} - Cp^{m-3} + \&c. + N = R;$$

and by substituting another quantity, q , for it, we obtain

$$q^m - Aq^{m-1} + Bq^{m-2} - Cq^{m-3} + \&c. + N = -S;$$

then, I say, that there is at least one real value of x between the limits p and q ; that is, x is less than the former, and greater than the latter. The truth of the proposition, however, is better demonstrated from a partial than from a general example.

Let us, therefore, assume the equation

$$x^3 - 13x^2 + 7x - 1 = 0;$$

here, if we substitute $x = 2$, and $x = 20$, we have a result in the first case $= -31$; and in the second $= +2939$; and it remains to be shewn that there is, at least, one real value of x comprised between these limits. For this purpose, the equation may be written

$$x^3 + 7x - (13x^2 + 1)$$

which quantity is found to be negative when $x = 2$; but positive when $x = 20$. That is, in the first case, we have

$$(x^3 + 7x) < (13x^2 + 1),$$

and in the latter

$$(x^3 + 7x) > (13x^2 + 1).$$

Now, it is obvious, that each branch of these expressions will increase as x is augmented, and that they will likewise be each diminished as x is diminished. Let us, therefore, conceive x , in the first case, to be successively increased by any small quantity, till it arrives at the value of x in the second case. Then, since $x^3 + 7x$, which was at first less than $13x^2 + 1$, is now become greater than $13x^2 + 1$, it must necessarily have passed through that state, in which it was neither greater nor less; that is, the two branches must have passed through that state in which they were equal; but when

$$x^3 + 7x = (13x^2 + 1),$$

we have also

$$x^3 - 13x^2 + 7x - 1 = 0;$$

and, consequently, this value of x is a real root of the equation proposed.

This reasoning, though employed only in a particular case, is equally applicable to our general equation: for, by putting the positive part of the equation $= P$, and the negative $= Q$; also, supposing p to be that value of x which renders the result negative, or, which is the same, which gives $P < Q$; and q that value which makes $P > Q$, then we may conclude the same as above, that P , from being less than Q , having passed to that state in which it is greater than Q , there must necessarily be a real value of x , between p and q , which renders $P = Q$; or the proposed equation $= 0$. We may also ascertain the limits of x between 0, and some real quantity, positive or negative. For example, in the general equation

$$x^m - Ax^{m-1} \pm Bx^{m-2} - Cx^{m-3} \pm \&c. \pm N = 0,$$

it is obvious, that by taking $x = 0$, the result will be negative or positive, according as N is affected with the sign $-$ or $+$. Therefore, if, in the first place, we find p such that

the result is positive, and $x = 0$, making it negative, a real value of x must lie between the limits p and 0. Again, the above equation may be converted into another, having the same roots, only with contrary signs, by writing $-y$ for x . And let us suppose, in the first place, that m is even, then the transformed equation will be

$$y^m + Ay^{m-1} \pm By^{m-2} + Cy^{m-3} \&c. \pm N = 0;$$

and, consequently, N will still have, with regard to y^m , the same sign, which, as above, we suppose to be negative; then, if q be such as will give a positive result, and $x = 0$ giving a negative, it follows, that a real value of y will be found between the limits q and 0; and, consequently, in the equation proposed, a real root is comprised between the limits $-q$ and 0.

But if the power m be odd, then the transformed equation will be

$$-y^m - Ay^{m-1} \mp By^{m-2} - Cy^{m-3} \mp \&c. \pm N = 0,$$

$$\text{or, } y^m + Ay^{m-1} \pm By^{m-2} + Cy^{m-3} \pm \&c. \mp N = 0;$$

and, consequently, y^m and $\mp N$, have not the same sign with regard to each other. If, therefore, now, any value q can be found, such that the result may be negative, a root of this equation will be found between the limits q and 0, and, therefore, in the original one between $-q$ and 0.

2. The greatest positive root of an equation is always contained between the limits $S + 1$ and 0; S being the greatest negative co-efficient that enters into the equation.

In order to prove this, we must demonstrate that in any expression

$$x^m \pm Ax^{m-1} \pm Bx^{m-2} \pm Cx^{m-3} \&c. + N.$$

The first term may be made to exceed the sum of all the other terms. Now, it is obvious, in the first place, that the case which presents the greatest difficulty, is that in which all the co-efficients are made negative, and each equal to the greatest; let, then, S be the greatest negative co-efficient, it is to be demonstrated, that such a value of x may be found as will render

$$x^m > S(x^{m-1} + x^{m-2} + x^{m-3} + \&c. + 1).$$

Or, since the part within the parenthesis is equal to $\frac{x^m - 1}{x - 1}$, we have to shew, that we may find x such, that

$$x^m > \frac{S(x^m - 1)}{x - 1}, \text{ or } x^m > \frac{Sx^m}{x - 1} - \frac{S}{x - 1}.$$

Now, this will be manifestly the case, if we make

$$x^m = \frac{Sx^m}{x - 1}, \text{ or } 1 = \frac{S}{x - 1}, \text{ or } x = S + 1.$$

It is therefore obvious, that this value, substituted for x in the proposed equation, will give a positive result; whereas, $x = 0$ gives a negative result: therefore, from what is shewn above, a real value of x is found between the limits $S + 1$ and 0. If the foregoing equation be converted into another, with the signs of the roots changed, and if R in that equation be the greatest negative co-efficient, then $-(R + 1)$, and 0, will be the limits also of the greatest negative root.

It follows, immediately from what is shewn above, that every equation of even dimensions, having its last term negative, has at least two real roots, the one positive and the other negative.

It may also be readily demonstrated, upon similar principles, that every equation of odd dimensions has at least one real

real root ; a truth which it is difficult to prove in any other manner. See La Croix's *Elemens de Algebra*, and La Grange's work above quoted.

LIMITS, in a *Military Sense*, denote the distance which a centry is allowed on his post, viz. fifty paces to the right, and as many to the left ; and though the weather be ever so bad, he must not get under cover.

LIMITS of a *Planet*, its greatest excursions or distances from the ecliptic. See PLANET.

LIMITANEI, among the Romans, an appellation given to the soldiers who were stationed on the frontiers of the empire.

LIMITROTOPHI, among the Romans, the same with limitanei.

LIMMA, or LEIMMA, an interval of the *Greek Music*, which is a comma less than the semitone major, and, re-trenched from a tone major, leaves behind the *Apotome* ; which see.

The ratio of the limma is 243 to 256, and is generated by beginning at C, and moving by 5ths to B ; for then the quantity by which the neighbouring C exceeds B, is precisely in the ratio which we have established.

Philolaus, and all the Pythagoreans, made the limma a diatonic interval, which answered to our semitone major : for, after two conjunctive tones major, there remains only that interval to complete the true 4th, or tetrachord. So that, according to them, the interval from E to F was less than that from F to F#. Our chromatic scale gives quite the contrary. Rousseau.

The abbé Roussier has given the musical etymology of the word leimma, according to Aristoxenus. Mem. sur la Mus. des Anc. p. 142.

LIMMAT, in *Geography*, a river of Switzerland, which rises in the Alps, about 11 miles S. of Glarus, assuming the name of Lint or Linth, and having passed Glarus and joined the Mat, near the lake of Wallenstadt, takes the name of Limmat, and having traversed the lake of Zurich, joins the Aar, three miles N. of Baden. The stream of this river is very rapid ; its water beautifully transparent ; and its borders, at first flat, afterwards gently rising into hills clothed with pasture and wood, or divided into vineyards, and at last becoming quite perpendicular, and fringed to the water's edge with hanging trees. About a mile from Baden, where the Limmat flows with the greatest rapidity, is a beautiful wooden bridge, 240 feet long, and suspended about 20 feet from the surface of the water. It was the last work of Grubenman, the self-taught architect, and is far superior in elegance to that of Schaffhausen.

LIMMEN, a town of Holland ; 5 miles S. of Alcmær.

LIMNÆUS, JOHN, in *Biography*, an eminent German jurist, was born at Jena in 1592, where his father was professor of mathematics. Having received a good education in the elements of learning, he went to Weimar to pursue his maturer studies, and from thence to the university of his native place, where he remained till the death of his father in 1614, when he removed to Altdorf. In 1618, he engaged himself as travelling tutor to two young men of Nuremberg, whom he accompanied to France, England, and Holland. Having finished his engagement with these, he took upon himself the office of private tutor to several young persons of rank, among whom was Albert, margrave of Brandenburg. In process of time, this prince gave him the post of chamberlain and member of his privy council. He died in the enjoyment of these offices in the year 1663. His works are numerous, and valued for their erudition. The chief are, "Tractatus de Academiis," 4to. ; "Notitie

Regni Gallie," 2 vols. 4to. ; "De jure imperii Romano-Germanici," 5 vols. 4to. Moreri.

LIMNER, corrupted from the French word *enlumineur*, a decorator of books with initial or other pictures. Johnson.

LIMNIA, in *Botany*. See CLAYTONIA.

LIMNING, (from *enluminer*, Fr. *to adorn books with paintings*). As these paintings, or illuminations, as they are called, were always done in water-colours, limning is never properly employed, except it be to designate that species of art, which is now commonly known by the name of miniature-painting, wrought in those colours, and on paper ; indeed, it is become almost obsolete, though, in the minds of the vulgar, it is sometimes used to signify the art of painting generally, and more particularly *Portrait-painting* ; which see. See also the articles MINIATURE and WATER-COLOURS.

LIMNITIS, a word used by the ancients to express the concretion of round reeds, or water-plants, by some called *adarse* : or somewhat analogous to that.

LIMNOPEUCE, in *Botany*, from *λίμνη*, a pool or lake, and *πέυκη*, a pine-tree, a name given by Vaillant to the *Pinifolia* of Dillenius, *Hippuris* of Linnæus, in allusion to its spiry shape and watery habitation. See HIPPURIS.

LIMNOPHILA, from *λίμνη*, a pool or lake, and *φιλή*, to love, because it inhabits such places. Brown Prod. Nov. Holl v. 1. 442. Class and order, *Didymia Angiosperma*. Nat. Ord. *Perfonata*, Linn. *Scrophularia*, Juss.

Eff. Ch. Calyx tubular, five-cleft, equal. Corolla funnel-shaped ; limb in five nearly equal segments. Stamens within the tube ; anthers cohering in pairs. Stigma dilated, oblique. Capsule of two cells, and two deeply divided valves, the partition inserted into that edge of the valves which bursts latest.

Herbs that inhabit marshes, with opposite deep-cut leaves, mostly divided into three parts to the base, which gives them the appearance of being whorled. Flower-stalks axillary, with two bractæas at the top.

The only species named by the author is

L. gratioloides. (Hottonia indica ; Linn. Sp. Pl. 208. H. flore solitario ex foliorum alis proveniente ; Burm. Zeyl. 121. t. 55 f. 1. Tsjudan-tsjera ; Rheede Hort. Malab. v. 12. 71 t. 36.)—Gathered in the Tropical part of New Holland by Mr. Brown, who suspects that several species are confounded by botanists under the above denomination, to be ascertained by examination of them in a recent state only. It is remarkable that the plant of the *Hortus Malabaricus* is said to grow in a dry sandy soil. See HORTONIA.

LIMO. See CITRUS.

LIMOCINCTI, among the Romans, a kind of priests, who officiated at public sacrifices, and were dressed with a garment called *limus*.

LIMODORUM, in *Botany*, *λίμωδωρον*, a sort of parasitical plant, or rather, as it should seem, some kind of tare, it being said to choke or suffocate the *sanum græcum*. By this latter name we are not perhaps to understand literally the fennugreek or *Trigonella*, but may extend it to any other plant cultivated for hay in Greece, as more than one of the leguminous tribe are, or have been. Dodonæus applied this ancient name to the *Orobanche*, or Broom Rape ; Clusius to the *Orchis abortiva* of Linnæus ; which at least is what he described and intended. in his *Stirp. Pannon.* 241, though in his *Hystoria* acut. of *Ophrys Nidus-Avis*, by mistake, annexed to that description. Linnæus, having referred the plant of Clusius to the genus *Orchis*, adopted the name in question for a new genus of the same natural order ; but Swartz. in his excellent treatise on this order, having referred the Lin-

near *Limodorum* to his *Cymbidium*, very properly restores the name to the original plant of Clusius, which proves distinct in genus from *Orchis*, as Tournefort had done before him. Clus. Hist. v. 1. 270. Tourn. t. 250. Swartz. Orchid. in Schrad. N. Journ. v. 1. 84. t. 1. f. 4. Ind. Occ. 1519. Willd. Sp. Pl. v. 4. 122.—Class and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*, Linn. Juss. Brown. Prodr. Nov. Holl. v. 1. 309.

Gen. Ch. reformed. *Cal.* Perianth of three, generally spreading, equal leaves, rarely reversed. *Cor.* Petals two, generally smaller than the calyx-leaves. Nectary a spreading lip, undivided or lobed, concave at the base, projecting behind in a spur, various in figure and length. *Stam.* Another an hemispherical, sometimes pointed, terminal, deciduous lid, of two or four cells; masses of pollen stalked, in pairs. *Fyl.* Germen inferior, oblong, or obovate, nearly upright, furrowed; style semi-cylindrical, often gibbous, concave in front; stigma concave or convex, in the front of the style near the top. *Peric.* Capsule oblong, with three or six ribs, with one cell and three valves, opening by clefts between the ribs. *Seds.* numerous, minute, each clothed with a chaffy tunic, inserted into the downy internal ridges of the valves.

Eff. Ch. reformed. Calyx-leaves somewhat spreading. Lip spreading, elongated at the base behind into a spur. Anther a terminal lid, deciduous.

Dr. Swartz enumerates twenty-one species, besides a doubtful one, which is *Rodriguezia* of the Prodr. Fl. Peruv. et Chil. t. 25. Professor Willdenow has twenty-seven species, for though he omits the six last of Swartz's, having, perhaps, not seen Schrader's New Journal, in which, and in its reprint the *Genera et Species Orchidearum*, only, they are described; he has added twelve others, which Swartz had only in part indicated as doubtful. All these are adopted by Willdenow from books; the six whose descriptions he had not seen, were all gathered by Dr. Afzelius at Sierra Leone.

This genus differs from *Cymbidium* in having a spur to the nectary, in whose cavity the honey is lodged. We have however already mentioned, (see *CYMBIDIUM*.) that this character, though apparently decisive, is overset by some nondescript *Orchideæ*, found by Dr. Buchanan in the East Indies. These, by every mark, except the absence or presence of a spur in which they totally differ among themselves, must form one genus, differing in habit from every thing already known; and we have little doubt that a critical examination of them recent, would be the means of detecting some over-ruling character, which would stamp this genus, independent of all that concerns the spur. In that case, the latter might still remain a sufficient distinction between *Limodorum* and *Cymbidium*.

Some remarkable species of *Limodorum* are

L. Tankervilleæ. Banks in Ait. Hort. Kew. ed. 1. v. 3. 302. t. 12. Andr. Repos. t. 426. Willd. n. 1. (*Phaius grandifolius*; Loureir. Cochinch. 529.)—Leaves radical, elliptic-lanceolate, pointed, ribbed, plaited. Stalk simple, many-flowered. Lip convoluted, with a very short spur.—Native of China. It is treated in Europe as a stove plant, flowering in the spring. We first saw it at Lady Tankerville's in 1786, and it blossomed that year at Haarlem. The great size of the whole plant, which much exceeds that of any other of this natural order, whether wild or cultivated in Britain, and the splendidly contrasted colours of the flowers, render it much admired. The inside of the calyx and petals is cinnamon-coloured, the outside of the most brilliant polished white; the nectary crimson, often compared, though certainly inferior in beauty, to the foxglove.

L. abortivum. Willd. n. 26. (*L. austriacum*; Tourn. Inst. 437. *Orchis abortiva*; Linn. Sp. Pl. 1336. Jacq. Austr. t. 193. *Epipactis*, n. 1288. t. 36. Hall. Helvet. v. 2. 148.)—Leaves none. Stalk with several tubular sheaths. Flowers but little spreading. Lip wavy. Spur awl-shaped, the length of the germen.—Native of shady woods in Germany, Italy, the south of France, and some parts of Switzerland, but rare even in that country of *Orchideæ*. That it has no right to a place in the Flora of Britain, though admitted by Ray and Hudson, is now generally allowed. The mistake arose from its being confounded in old books with *Orchanebe cerulea*, Engl. Bot. t. 423, as is minutely explained at length in Tr. of Linn. Soc. v. 4. 164—169, and it appears that Lobel's *Orchanebe major*, e *Gramontio lucco Monspeliensium*, Lob. Ic. v. 2. 269. f. 1, which is *Orchanebe monspeliaca floribus oblongis*, Ger. em. 1312, is certainly this *Limodorum*. The root consists of two biennial clusters of thick, cylindrical, divaricated fibres. The stalk is simple and solitary, eighteen to twenty-four inches high, clothed with a few close purplish sheaths, and terminating in a close spike of rather large flowers, variegated with paler and deeper purple.

L. Epipogium. Willd. n. 27. (*Epipogium*; Gmel. Sib. v. 1. 11. t. 2. f. 2. *Satyrium Epipogium*; Linn. Sp. Pl. 1338. Jacq. Austr. t. 84. *Epipactis*, n. 1289. Hall. Helvet. v. 2. 149.)—Leaves none. Stalk sheathed. Flowers few, pendulous, reversed. Lip three-lobed, concave. Spur ovate, ascending.—This singular and rare plant grows in some shady barren forests in Siberia, Germany, and Switzerland. Its pale hue and fleshy habit, so like *Epipactis* *Aridus-Avis*, indicate its being a parasitical attendant on the roots of trees. See *EPIPACTIS*, n. 9; and *EPIPOGIUM*.

Dr. Swartz refers also to this same genus the *Cypripedium bulbosum*, Linn. Sp. Pl. 1347. Sm. Spicil. t. 11, a most curious plant, found in Lapland and Nova Scotia, of which very little is known; but the propriety of this measure is in our opinion very doubtful.

LIMODORUM, in *Gardening*, contains plants of the bulbous-rooted herbaceous perennial kind, of which the species commonly cultivated are the tuberous-rooted *limodorum* (*L. tuberosum*); the tall *limodorum* (*L. altum*); and the Chinese *limodorum* (*L. Tankervilleæ*.)

Method of Culture.—These plants are increased by planting the offsets from the roots in pots of bog-earth, and plunging them, in the first sort, in a mild tan-pit, and in the others, in the tan hot-bed of the stove. The proper time of taking them off is when the plants are the most destitute of leaves.

But the two last sorts should have a loamy mould, and but little water in the winter season. And the first requires the protection of a good green-house in winter, but the two last should be kept in the bark-bed of the stove.

All these plants afford variety in green-house and stove collections.

LIMOGES, in *Geography*, a city of France, and capital of the department of the Upper Vienne; and before the revolution, the see of a bishop. It is a place of considerable trade, and contains about 20,550 inhabitants, and 25,466 in the two cantons, on a territory of 292½ kilometres, in 11 communes. N. lat. 45° 50'. E. long. 1° 20'.

LIMON, in *Botany*, Tourn. 397, the Lemon. See *CRATUS medica* β

LIMON, in *Geography*, a small island in the W. side of the gulf of Bothnia. N. lat. 60° 44'. E. long. 17° 9'.

LIMONA de la Trou, a town near the N. coast of the island of Hispaniola; 15 miles S.E. of Cape Francois.

LIMONE, a town of France, in the department of the Maritime

Maritime Alps; S. of Cani.—Also, a town of the island of Negropont; 20 miles S. of Negropont.

LIMONES, GRANDE, a town of the island of Cuba; 50 miles S. of Havana.

LIMONEST, a town of France, in the department of the Rhône, and chief place of a canton, in the district of Lyons. The place contains 750, and the canton 11,089 inhabitants, on a territory of 77½ kilometres, in 12 communes.

LIMONHE, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors; 13 miles E. of Cahors. The place contains 1175, and the canton 9279 inhabitants, on a territory of 255 kilometres, in 13 communes.

LIMONIA, in *Botany*, in its present application, evidently alludes to *Limon*, the lemon; the genus which is so denominated being next akin to *Citrus*, in characters, habit, and sensible qualities. The word therefore can have no reference to the λεμονια of the Greeks, *Limonia* of the Romans, which is a species of *Anemone*, and derives its name from λεμον, a meadow.—Linn Gen. 213. Schreb. 285. Willd. Sp. Pl. v. 2. 571. Mart. Mull. Dict. v. 3. Ant. Hort. Kew. ed. 2. v. 3. 43. Juss. 261. Lamarck Illustr. t. 353. Gært. t. 58.—Class and order, *Dicandria Monogynia*. Nat. Ord. *Aurantiæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, very small, in from three to five, more or less deep, segments, permanent. Cor. Petals from three to five, oblong, obtuse, erect, spreading at the summit. Stam. Filaments from six to ten, awl-shaped, erect, shorter than the corolla; anthers linear, erect. Pist. Germen oblong, superior; style cylindrical, the length of the stamens; stigma capitate, flat. Peric. Berry ovate, or nearly globose, of three cells, with membranous partitions. Seeds solitary, ovate.

Eff. Ch. Calyx in from three to five deep segments, inferior. Petals three to five. Berry of three cells. Seeds solitary.

Three species of this genus, all tropical spinous shrubs, and much resembling orange trees in miniature, were known to Linnæus. Five without spines, adopted from Forster, Lamarck and Retzius, are added by Willdenow. Two more from the East Indies, described by Dr. Roxburgh, one with and one without spines, are mentioned in Mr. Aiton's new edition.

Examples of the spinous species are

L. monophylla. Simple-leaved Thorny Limonia. Linn. Mant. 237. Roxb. Corom. v. 1. 59. t. 83. (*Limones pumili zeylanici sylvestres*; Burm. Zeyl. 143. t. 65. f. 1.)—Leaves simple. Spines solitary.—Native of the East Indies, in the extensive forests of the coast of Coromandel, where it is called by the natives the Wild Lime. This is a shrub or small tree, with alternate, stalked, ovate, entire, obtuse, evergreen, shining leaves, full of pellucid dots, as are those of all the rest, and each accompanied by a sharp axillary thorn. The flowers are white, in axillary clusters. Petals four. Stamens ten, united into a firm hemispherical cup. Berry the size of a very small gooseberry, brownish, of four cells, thickly coated.—Notwithstanding the monadelphous stamens and simple leaves, this species has too entirely the habit of the rest to be separated from them.

L. trifoliata. Three-leaved Limonia. Linn. Mant. 237. Jacq. Ic. Rar. t. 463. Andr. Repof. t. 143.—Leaves ternate. Spines in pairs.—Native of the East Indies. It makes a pretty appearance in the stove, when decorated either with its white blossoms, which are three-cleft and hexandrous, or its scarlet berries, which are sweet and pleasantly acid. The leaflets are emarginate, the central

one largest. Branches zigzag and slender.—When this shrub flowered some years since at Vienna, it answered so ill to the character of *Limonia*, in number of parts, that the celebrated Jacquin was near making a new genus of it, which he destined to honour an English botanist. There can be no doubt however that it belongs to *Limonia*. "Le petit citron doux" of Sonnerat, Voy. to New Guinea, 102. t. 63, is made a variety of this by Willdenow, who, judging by the figure, not the description, improperly says it has no spines. The sessile leaves, and solitary flowers, give it a different appearance.

Of the unarmed species are

L. pentaphylla. Five-leaved Limonia. Retz. Obf. fasc. 5. 24. Roxb. Corom. v. 1. 60. t. 84.—Spines none. Leaves pinnate; leaflets elliptical, entire, two pair with an odd one.—Native of the East Indies. The flowers are small and white, exquisitely fragrant, in axillary branched clusters. Fruit red, the size of a currant. Stamens ten, distinct, spindle-shaped.

L. arborea. Tree Limonia. Roxb. Corom. v. 1. 60. t. 85.—Spines none. Leaves pinnate; leaflets ferrated, oblong, two pair with an odd one.—From the same country. The flowers are very numerous, in branched clusters, fragrant. Fruit small, brown. Stamens thread-shaped.

LIMONIA, in *Geography*, an island in the Mediterranean, about three miles long, and one broad; six miles W. of Rhodes. N. lat. 36° 27'. E. long. 27° 22'. On its eastern coast is a small haven, defended by a shoal, on the margin of which stands the only village in the island. At some distance from Limonia is Narki, or Karki, anciently Chalcia, or Chalcis, which seems by several shoals that rise above the waters to have formerly joined with Limonia.

LIMONIUM, in *Botany*, derived, as it appears, from λεμον, a meadow, (because the plant occupies, to a great extent, low tracts of land on the sea-shore,) is the old name for several species of Sea Lavender. (See STATICE.) The same name has been also applied to the Red Valerian, to the Buck-bean, and even to the *Pyrola rotundifolia*. The latter indeed does grow on low sandy commons in Holland, and near Yarmouth, but likewise in the most elevated heathy alpine places; nor, as far as we know, in scarcely any intermediate station; for what is so named in books is often *P. minor*. The coincidence of alpine and maritime plants, found in no other situations, is a curious problem for the vegetable physiologist.

LIMONIUM-Gall, in *Natural History*, the name of a species of gall or vegetable protuberance, serving for the lodging of an insect, affording a very beautiful appearance on the plant, and very common in the eastern parts of the world.

This of the limonium is singular, in that it is produced from a butterfly egg, and is inhabited by a true caterpillar. The butterfly deposits her eggs on several parts of the leaves and stalks of this plant, and the young caterpillar, as soon as hatched, eats its way through the surface; and continuing to eat when within, his depredations occasion an abundant derivation of juices to the part, by means of which a gall, or protuberance, is formed, which is sustained by a pedicle, and in all respects resembles a fruit. This is of a roundish figure, and by degrees grows to the size of a nutmeg. It is composed of several coats, or crusts; the exterior ones are soft and spongy, but the interior are harder, and more woody than the galls of the oak. As the generality of other caterpillars feed on the substance of the leaves of trees and plants, this eats only the inside of its lodgment; and nature so readily supplies this defect by new matter, that the

the cavity, in which it is lodged, is never found to be very great.

This seems the only known instance of a gall formed by a genuine caterpillar, the inhabitants of the willow galls, though usually esteemed smooth caterpillars, being not so, but the worms of a four-winged fly. Reaumur's Hist. of Insects, vol. vi. p. 227.

LIMOSA, in Ornithology, the scolopax glottis of Linnaeus, the name of a long-legged water-bird, common in Italy, and called by some *glottis*, and *pluvialis major*. See also *Scolopax limosa*, *fusca* and *Fedoa*, *Tetanus*, &c. &c. and *RECURVIROSTRA Americana*.

LIMOSA, in Ichthyology, a name given by Salvian to the common mackerel, and in his figures to the *thynnus*, or tunny-fish, called the *Spanish mackerel*. See *Thynnus* *SCOMBER*.

LIMOSANO, in Geography, a town of Naples, in the county of Molise; 17 miles N.E. of Molise.

LIMOSELLA, in Botany, derived from *limus*, mud, from the circumstance of its growing and thriving in muddy pools and ditches. For the same cause it has obtained the English appellation Mudwort.—Linn. Gen. 320. Schreb. 419. Willd. Sp. Pl. v. 3. 341. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 668. Ait. Hort. Kew. 2. 359. Brown Prod. Nov. Holl. 443. Juss. 96. Lamarck Illustr. t. 535. Gærtn. t. 50.—Class and order, *Didymia Angiospermia*. Nat. Ord. *Precie*, Linn. *Lyfsmachia*, Juss.

Gen. Ch. Cal. Perianth of one leaf, five-cleft, erect, acute, permanent. Cor. of one petal, bell-shaped, erect, equal, five-cleft, acute; divisions spreading. Stam. Filaments four, erect, two of them adhering to the same side, shorter than the corolla; anthers simple. Pist. Germen superior, oblong, obtuse; style simple, as long as the stamens, reclining; stigma globose. Peric. Capsule ovate, half covered by the calyx, of one cell and two valves. Seeds numerous, oval. Recept. ovate, very large.

Ess. Ch. Calyx five-cleft. Corolla five-cleft, equal. Stamens approaching each other in pairs. Capsule with one cell, two valves, and many seeds.

1. *L. aquatica*. Common Mudwort. Linn. Sp. Pl. 881. Engl. Bot. t. 357. Fl. Dan. t. 69. (*Spergula perpusilla lanceatis foliis*; Loes. Prof. 261. t. 81.)—Leaves lanceolate.—Found in muddy pools where water has been standing. Dr. Abbot sent it to Mr. Sowerby from Bedfordshire, and Dr. Smith has gathered it on the Denes at Lowestoft in Suffolk. It flowers in July and August.—Root annual, creeping. Stems prostrate, cylindrical. Leaves radical, on long footstalks, smooth, entire, not involute. Flowers small, flesh-coloured. Calyx somewhat irregular, acute, smooth. Capsule with a groove along its upper side.

2. *L. diandra*. Diandrous Mudwort. Linn. Mant. 252. Koenig.—Leaves somewhat linear.—A native of the East Indies and the Cape of Good Hope.—The habit of this species is exactly similar to that of the last, but the plant is only about a fourth as large in all its parts, so that it may be considered as one of the smallest of all plants. Stems creeping, short. Leaves radical, linear, scarcely widening in the middle, obtuse. Linnaeus complains that on account of the minuteness of the flowers he could not describe them from a dried specimen, but that the acute discoverer of this species, Koenig, found them to be diandrous.

3. *L. australis*. New Holland Mudwort. Brown. Prod. Nov. Holl. 443.—Leaves spatulate linear.—We know nothing of this species, but we insert it, on the authority of Mr. Brown, as a native of New Holland, who justly observes that all the species stand in need of further investigation.

LIMOURS, in Geography, a town of France, in the

department of the Seine and Oise, and chief place of a canton, in the district of Versailles; nine miles S. of Versailles. The place contains 858, and the canton 7304 inhabitants, on a territory of 147½ kilometres, in 14 communes.

LIMOUX, a town of France, and principal place of a district, in the department of the Aude. N. lat. 43° 3'. E. long. 2° 18'. The place contains 5142, and the canton 12,556 inhabitants, on a territory of 240 kilometres, in 23 communes.

LIMPET, in Conchyliology. See PATELLA and CONCHIOLOGY.

LIMUS, among the Romans, a garment reaching to the ground, and worn by the priests, who on that account were called *limocincti*.

LINACAGAN, in Geography, one of the islands in the East Indian sea, called Calamianes. N. lat. 11° 40'. E. long. 120° 10'.

LINACRE, THOMAS, in Biography, an eminent physician, and one of the most elegant scholars of his age, was born at Canterbury about the year 1460. Having completed his school-education, under a very eminent master, in his native city, he entered at Oxford, and was chosen fellow of All-Souls' college in 1484. His desire of farther advancement in learning induced him to accompany his former schoolmaster, De Selling, into Italy, whither the latter was sent on an embassy to the court of Rome by Henry VII. De Selling left him at Bologna, with strong recommendations to Angelo Poliziano, who was at that time accounted one of the most elegant Latinists in Europe; but whom our young student, by his assiduous application, at length excelled in the purity of his style in that language. At Florence, Linacre had the good fortune to acquire the favour of that munificent patron of literature, Lorenzo de Medicis, who granted him the privilege of attending the same preceptors with his own sons. He knew how to profit by such an opportunity; and under Demetrius Chalcondylas, who had fled from Constantinople when it was taken by the Turks, he acquired a perfect knowledge of the Greek language. Thus accomplished in classical learning, he went to Rome, and studied medicine and natural philosophy under Hermolaus Barbarus. He applied particularly to the works of Aristotle and Galen, and is said to have been the first Englishman who was well acquainted with those writers in the original Greek. On his return to England, he took the degree of doctor of physic at Oxford, and gave lectures on physic and taught the Greek language in that university. His reputation soon became so high, that king Henry VII. called him to court, and entrusted him with the care both of the health and education of his son, prince Arthur. He is said also to have instructed princeess Catherine in the Italian language. He was made successively physician to the kings Henry VII., Henry VIII., and Edward VI., and to the princeess Mary.

In the reign of Henry VIII., indeed, he appears to have stood above all rivalry at the head of his profession; and he evinced his attachment to its interests, as well as to the public good, by various acts; but especially by founding two lectures on physic in the university of Oxford, and one in that of Cambridge, and by obtaining the institution of the Royal College of Physicians in London. He saw with concern, that the practice of medicine was chiefly engrossed by illiterate monks and empirics, licences being easily obtained by improper persons, when the bishops were authorized to examine and license practitioners in an art of which they could not be competent judges. Through the interest of cardinal Wolsey, therefore, Linacre obtained letters patent in 1518 from Henry VIII., constituting a corporate body

body of regularly bred physicians in London, in whom was vested the sole right of examining and admitting persons to practise within the city, and seven miles round it; and also of licensing practitioners throughout the whole kingdom, except such as were graduates of Oxford or Cambridge, who by virtue of their degrees were independent of the college, except within London and its precincts. The college had likewise authority given to it to examine prescriptions and drugs in apothecaries' shops. Linacre was the first president of the new college, and continued in the office during the remaining seven years of his life; and, at his death, he bequeathed to the college his house in Knight-riding-street, in which its meetings were held. There is no doubt that this institution greatly contributed to the credit and dignity of the medical profession in the metropolis, and many justly celebrated names are enrolled among its members. In process of time, however, its foundation became narrowed, and it fell into the usual monopolizing spirit of a corporation, whilst its powers to controul the audacity of empirical impostors (the principal object of its establishment) have sunk into total disuse.

Towards the latter part of his life, in the year 1519, Linacre entered into holy orders; a step to which, it would seem, he was principally induced, from a desire to obtain a studious and easy retirement, at a time when he became exceedingly afflicted with that painful disease, the stone, which greatly incapacitated him for business, and at length put an end to his life. Sir John Cheke relates that, not long before his death, when worn out by sickness and fatigue, he first began to read the New Testament; and that when he had perused the fifth, sixth, and seventh chapters of St. Matthew, he threw the book from him with violence, exclaiming, "either this is not the gospel, or we are not Christians!" a declaration, if rightly understood, equally honourable to the morals he found there inculcated, and satirical to those of the age. He died in great agonies from the stone, on the 20th of October, 1524, at the age of sixty-four, and was buried in St. Paul's cathedral, where a monument was afterwards erected to his memory by his admirer and successor in fame, Dr. Caius.

In his literary character, Linacre stands eminently distinguished; inasmuch as he was one of the first, in conjunction with Collet, Lilly, Grocin, and Latimer, who revived, or rather introduced, the learning of the ancients in this island. Translations from the Greek authors into Latin were the chief occupations of the literati of those times; and Linacre conferred a benefit on his profession, by translating several of the most valuable pieces of Galen. These were the treatises, "De Sanitate tuenda," in six books, which was printed at Cambridge in 1517, and dedicated to king Henry VIII.; "De Morbis curandis," in fourteen books, printed at Paris in 1526; three books, "De Temperamentis," and one "De inæquali Temperie," first printed at Cambridge in 1521, and inscribed to pope Leo X.; "De naturalibus Facultatibus," three books, together with one book "De pulsum Usu," the first time of printing, which is unknown, but they were reprinted by Colihæus in 1528, as well as his posthumous translation of the four books "De Morborum Symptomatibus." In these versions Linacre exhibited a Latin style so pure and elegant, as ranked him among the finest writers of his age: it was laboured, indeed, with that solicitude of correctness, which bespoke a Latinist formed in the Italian school of that time. His friend Erasmus describes him as "Vir non exacti tantum, sed severi judicii;" and Huet, in his learned treatise "De claris Interpretatoribus," gives him the praise of extraordinary elo-

gance and chasteness of style, but intimates that he occasionally sacrifices fidelity to these qualities.

It was, indeed, on his reputation as a philologist, that he seems chiefly to have valued himself. His first essay was a translation of "Proclus on the Sphere," dedicated to his pupil, prince Arthur; and he also wrote a small book of the rudiments of the Latin Grammar, in English, for the use of the princess Mary, which was afterwards translated into Latin by the celebrated Buchanan. But the work, which appears to have engaged a very large portion of his time, and was universally acknowledged to be a work of the most profound erudition, was a larger grammatical treatise, entitled "De emendata structura Latini Sermonis, libri sex." This work, which was not printed till after his death, in December 1524, when it appeared with a commendatory letter from the learned Melancthon, was received with much applause by men of erudition, and passed through several editions: it was too complex however, and too profound in metaphysical divisions, and in the philosophy of language, for popular use. His friend Erasmus, indeed, in his "Moriae Encomium," bestowed some good-natured raillery upon the author, for having tortured himself for twenty years by the subtleties of grammar, and, after forsaking other more important objects, thought himself happy in living long enough to establish certain rules for distinguishing the eight parts of speech.

In his professional character, Linacre acquired universal reputation, among his countrymen and contemporaries, for skill and practical ability, as well as for his learning; and he was equally the subject of applause and estimation as an upright and humane physician, a steady and affectionate friend, and a munificent patron of letters. It were sufficient of itself to justify this eulogium, to mention that he was the intimate friend of Erasmus. That great and worthy man frequently takes occasion to express his affection and esteem for his character and abilities; and writing to an acquaintance, when seized with an illness at Paris, he pathetically laments his absence from Linacre, from whose skill and kindness he might receive equal relief. The following epitaph, written by Caius, will be acceptable to the learned reader from the elegance of its composition.

"Thomas Lynacrus, Regis Henrici VIII. medicus; vir et Græcè et Latine, atque in re medica longe eruditissimus. Multos ætate sua linguantes, et qui jam animam despondent, vitæ restituit. Multa Galeni opera in Latinam linguam, mira et singulari facundia, vertit. Egregium opus de emendata structura Latini sermonis, amicorum rogatu, paulo aute morte edidit. Medicinæ studiosis Græcæ publicas lectiones duas, Cantabrigiæ unam, in perpetuum stabilivit. In hac urbe Collegium Medicorum fieri sua industria curavit, cujus et Præsidens proximus electus est. Fraudes dolosque mirè perosus; fidus amicis; omnibus juxta charus: aliquot annos antequam obierat Presbyter factus; plenus annis, ex hac vita migravit, multum desideratus, anno 1524, die 21 Octobris. Vivit post funera virtus. Thomæ Linacro clarissimo Medico, Johannes Caius posuit, anno 1557. See Aikin's Biog. Memoirs of Med. Friend's Hist. of Physic. Gen. Biog.

LINAGROSTIS, in *Botany*, from *λινον*, *thread*, and *αγροστis*, *grass*, the old name of the Cotton-grass. See *ERUOPHORUM*.

LINARES, in *Geography*, a town of Spain, in the kingdom of Jaen, six leagues from the Sierra Morena; only remarkable for a fountain with many jets, and the remains of a Roman aqueduct, by which water was conveyed to the ancient Castelo, now Cazlona. In the neighbourhood are

very rich lead mines, and one of a semi-metal, with which the emerald tint is given to porcelain. Two leagues from this town there is a silver mine, famous in the time of the Carthaginians, which belonged to the beautiful Himilcon, wife of Asdrubal. The Romans also worked this mine. It has a shaft 2000 feet deep, into which numerous galleries open. It was long neglected; but re-opened in the 17th century, when a vein of silver was found five feet broad: however, it has since been disregarded. It belongs to the town of Bæza.

LINARIA, in *Botany*, so called from having the habit and foliage of *Linum*, or Flax, is the Toad-flax. (See *ASTIRRHINUM*.) The French botanists are partial to the name, though certainly none of the bell; and as they divide the genus, retain *Astirrhinum* for such species only as have no spur.

LINARIA, in *Ornithology*. See FRINGILLA and LINNET.

LINARYD, in *Geography*, a town of Sweden, in the province of Smaland; 11 miles S.E. of Wexio.

LINATO, a town of Italy, in the department of the Olona, on the Lambro; 5 miles S.E. of Milan.

LINBO, a small island in the Adriatic. N. lat. 44° 37'. E. long. 14° 57'.

LINCH-CLOUT, in *Artillery*, the flat iron under the ends of the arms of an axle-tree, to strengthen them, and diminish the friction of the wheels. See CLOUTS.

LINCH-PIN, in *Rural Economy*, the small pin, in carts or other carriages, that is put upon the end of the axle-trees, to confine the wheels on them in a steady manner. See LINSPIRS.

LINCHANCHIA, in *Geography*, a town of Mexico, in the province of Yucatan; 25 miles N. of Merida.

LINCKIA, in *Botany*, so called by Micheli, in honour of John Henry Linck, an apothecary at Leipzig, fellow of the Royal Society of London, who died in 1734, at the age of 60. He wrote an account of the coffee-tree, from one which flowered in a garden near his residence, in 1724, and his treatise may be seen in the *Ephemerides* of the Acad. Naturæ Curioforum, v. 1. 204. He is also the author of a splendid work in folio, on the species of Star-fish, *Asterias*. The plant to which Micheli has given his name, see Mich. Gen. 126. t. 67, is *Tremella Nefsee* of Linnaeus. See TREMELLA.

LINCOLN, an ancient city in the county of that name, England, and a place of considerable importance in the ecclesiastical and military annals of the kingdom, is singularly situated on the top and side of an eminence, which slopes with a steep descent to the south, where the river Witham runs at its base. A large portion of the city, or rather suburbs, extends, in a long street, from the foot of the hill to the south. On the northern side of it, without the walls, is another suburb, called Newport, supposed to have been an outwork of the Roman station. Camden, and some other antiquaries, state, that this place was occupied as a station, or strong hold, by the Britons, anterior to the Roman colonization of the island; and that then it bore the name of "Lindcoit, from the woods (for which some copies have, corruptly, Lintcoit)." By Ptolemy and Antoninus the name of the place is written Lindum; and, from having the privilege of a colony, it was called Lindum colonia. As a military station, occupied by a colony of Romans, it must have been a place of some extent and consequence. This is evident from the vestiges that remain, and from the various discoveries that have been made at different periods. The form of the fortified station was that of a parallelogram, divided into four equal parts by two streets, which crossed it

at right angles. At the extremities of these were four fortified gates, nearly facing the four cardinal points. The whole was encompassed by an embattled wall, which, on three sides, was flanked by a deep ditch, but on the fourth side the steepness of the hill rendered a foss unnecessary. The area, thus inclosed, was about 1300 feet in length by 1200 in breadth, and is estimated to have contained thirty-eight acres. The walls have been levelled with the ground; and three of the gates have been long since demolished. The remaining gate, to the north, which is called Newport gate, is described by Dr. Stukeley as "the noblest remnant of this fort in Britain, as far as I know;" and he expresses much surprise, that it had not "been taken notice of" before his time. The great or central gateway has a semi-circular arch, sixteen feet in diameter, formed with twenty-six large stones, apparently without mortar. The height is twenty-two feet and a half, of which eleven are buried beneath the ground. On each side of the arch are seven courses of horizontal stones, called springers, some of which are from six to seven feet in length. On each side of the arch are two small lateral doorways or poiterns. A mass of the old Roman wall is still to be seen eastward of this gate; and to the west is another large mass, called the mint-wall, which was about sixteen feet high and forty feet long, and had scaffold-holes and marks of arches. Mr. Gough supposed this to be part of a Roman granary. Southward of the station above described were other Roman works, which extended from the brow to the bottom of the hill. It appears that a fortified wall, with towers at the corners, continued from the top to the bottom of the hill, where it turned at right angles by the side of the river. These fortifications underwent several alterations and additions, during the various wars to which the place was subjected. Hence it is very difficult, if not wholly impossible, to define what is really of Roman origin, or of Saxon or Norman workmanship. It is equally perplexing to ascertain the time of establishing the first colony here forming the station, building the walls, or extending the city. Various coins and other remains of antiquity have been discovered here. In 1739, three stone coffins were found at the south west corner of the clove, near the Chequer gate. Beneath these was a tessellated pavement, and under that a Roman hypocaust. A similar discovery was made in 1782. In the tenth volume of the *Archæologia* is a description of an ancient place of sepulture, discovered in an open field, half a mile from the east gate of the ancient Lindum. In 1790 was found, about three or four feet below the surface, a very curious sepulchral monument, evidently Roman, and of some person of high rank. Many fragments of antiquity were preserved by the Rev. Dr. Gordon, the precentor of the cathedral, who gives an account of several earthen and glass urns, which were discovered in the same field, some of which were of singular shape. He also describes a room, twenty feet by sixteen, which was discovered in a quarry. The same field having been broken up for the purposes of quarrying, several stone coffins of various shapes have at different times been discovered in the loose ground, which covers a substratum of rock. From these, and from other circumstances, it is highly probable that this was a Roman burial-ground.

Soon after the Romans quitted the island, Lincoln, in common with other places of consequence, shared in the general calamities which ensued by the incursions of the Picts, Saxons, and Danes. At what period the Saxons first possessed themselves of this city does not appear in history: but early in the sixth century we find Arthur, king of Britain, obtaining great advantages over the combined forces of

the two Saxon chiefs, Colgern and Cerdic, and compelling them to relinquish the siege of Lincoln. In those struggles the old town was nearly destroyed, and, as Leland supposes, "new Lincoln was made out of a piece of old Lincoln." The Saxons, for their better security, fortified the southern part of the hill with ditches and ramparts, walled the town, and erected gates. At the time of the Norman conquest, Lincoln appears to have been one of the richest and most populous cities in England: and of great importance as an emporium of trade and commerce. The Domesday Survey mentions 1070 manfions, 900 burgesses, and 12 lagemen, having sac and soke. On the accession of the Conqueror to the throne, he ordered four strong castles to be built; of which one was to be at Lincoln. In consequence of this, a large and strong castle was erected on the ridge of the hill, on which this city was situated. The building was 644 yards in circumference, and occupied the space on which it is asserted that 166 houses had stood; 74 more were at the same time demolished without the limits, that the whole might be insulated. In the reign of Henry I. a navigable canal was made, or enlarged, from the river Witham at Lincoln to the Trent near Torksey; and was probably the first canal of the sort ever made in England. This was about seven miles in length, and is at present called the Foss dyke. By this a communication was formed with the Trent, and down that by the Humber to the sea. Being thus accessible for foreign vessels, and having also the advantage of an inland navigation, the city became populous and wealthy; and, according to Alexander Nechain, a poet of that age, "Lincoln was now stored with good things, and became the support of the neighbouring country." At this period, it appears to have possessed a large share of the import and export trade of the kingdom. When, in the year 1140, the empress Maud came to England to assert her title to the crown, she took up her residence at Lincoln, as a place of safety, and conveniently situated for communication with her friends. Stephen hearing of it marched quickly thither, closely besieged the city, and took it: but the empress had escaped. The king, having possessed himself of the city, appeased the tumults of the neighbourhood, and finding the country quiet, left a garrison, and proceeded to his army, acting in other parts of the kingdom. During the contest between the empress and Stephen, Lincoln acquired great notoriety; and thence obtained a degree of consequence in the estimation of future monarchs. After Henry II. had been crowned in London, he was afterwards, according to Speed, crowned at Lincoln in the year 1155. We find this city and its castle materially concerned in the contentions between king John and the associated barons. The castle and bail of Lincoln appear to have continued in the occupation of the crown till the time of Edward I., when Henry de Lacy died seized of them, and they passed, with other parts of his inheritance, to the earl of Lincoln, and so became annexed to the duchy of Lancaster. John of Gaunt, duke of that palatinate, greatly improved the castle, and made it his summer residence; having, according to a local tradition, built himself a winter palace below the hill, in the southern suburbs. Several parliaments were held at Lincoln in the reigns of Edward I. II. and III. In the year 1348, the contracted spirit of monopoly so far prevailed here, against the acts of parliament passed in the years 1335 and 1337, and the king's resolutions to foster the woollen manufactures, that the weavers of Lincoln obtained a grant from Edward III., of what they considered and called their *liberties*. By this charter they were invested with the power of depriving any weaver not of their guild, of the privilege of working at his trade within twelve leagues of the city. This

and other similar monopolies were abolished in 1351, by an act called the *Statute of Cloths*. In the following year, the staple of wool was removed from Flanders to England; and Lincoln was one of the staple towns appointed on that occasion. It was also made a staple for leather, lead, and various other articles. This proved highly beneficial to the place, for it thereby recovered from the losses it had sustained by military ravages, and was soon restored to a flourishing condition. At the commencement of hostilities between Charles I. and his parliament, the king came to Lincoln, and convened the nobility and freeholders of the county.

The diocese of Lincoln, after the see was removed from Sidnacester, soon acquired a vast accumulation of territorial jurisdiction and wealth. It included so many counties, that it was described as ready to sink under the incumbent weight of its own greatness; and though Henry II. took out of it the diocese of Ely, and Henry VIII. those of Peterborough and Oxford, it is still considered the largest in England. As the jurisdiction was great, so, prior to the reformation, the revenues were proportionably abundant. Except the two archbishoprics, and those termed the principality bishoprics, Winchester, Durham, and Ely, no see was so well endowed, which was the reason that there is no record, prior to the time of Elizabeth, of any bishop of this see having been translated to another, except Winchester; though since that time, Willis observes, "no less than ten out of seventeen have left this for more valuable ones." Nor was it less remarkable for the number of episcopal palaces within the diocese. Previous to the year 1547, it had eight. In this county, Lincoln, Sleaford, and Nettleham; in Rutlandshire, Ledington; in Huntingdonshire, Buckden, the usual residence of the bishops; in Buckinghamshire, Woburn and Finghurst; in Oxfordshire, Banbury Castle: there were also two others at Newark in Nottinghamshire; and Lincoln Place, Chancery Lane, London. All these, except that at Lincoln, with about thirty manors, were given up, in the first year of Edward VI., by Holbech, the first married bishop; who, in order to gratify the wishes of some courtiers, and to raise his own family, exchanged almost every species of landed property annexed to the see for impropriations; so that now only four manors remain of the ancient demesnes. The present revenues, therefore, principally arise from rectorial property or tythes.

The cathedral is not only the most prominent object of this city, but is the most interesting as a subject of history, antiquity, and art. This magnificent structure, from its situation on the summit of a hill, and from the flat state of the country to the south-east and south-west, may be seen at the distance of twenty miles. Raised at a vast expence, by the munificence of several prelates, it discovers, in many parts, singular skill and beauty, particularly in its western front, which must attract the attention of every traveller. The see being translated from Dorchester to Lincoln in 1088, St. Remigius de Fescamp, the first bishop, founded a cathedral church, which was so far advanced in the course of four years as to be ready for consecration. All the bishops of England were summoned to attend on that occasion. Remigius died two days before the intended solemnity. His successor, Robert Bloet, finished the cathedral, dedicated it to the Virgin Mary, and greatly enriched it. In his time, the bishopric of Ely was taken out, and made independent of that of Lincoln. The cathedral, having been destroyed by fire in 1124, was rebuilt by Alexander de Blois, then bishop, who arched the new fabric with stone, to prevent a recurrence of a similar accident; and greatly increased the size and augmented the ornaments of it, so as to render it the most magnificent sacred edifice in his time.

LINCOLN.

Bishop Hugh Burgundus enlarged it by the erection of what is now called the New Work. He also built the chapter house. This prelate died in 1200. Two kings (John of England and William of Scotland) affixed to carry his body to the cathedral, where it was enshrined in silver, according to Stukeley; but Sanderfon says the shrine was of beaten gold. Bishop Gynewell added to the cathedral the chapel of St. Mary Magdalen. Bishop Fleming built a chapel on the north side, in which he was buried: on his monument is his figure in free-stone, pontifically habited. Bishop Alnwick was a considerable benefactor to the cathedral, and built the stately porch at the great south door. Bishops Russell and Longland built two chapels: to both these prelates are altar-tombs, though the latter was interred at Eton.

The cathedral church consists of a nave, with its aisles; a transept at the west end; and two other transepts, one near the centre, and the other towards the eastern end; also, a choir and chancel, with their aisles, of corresponding height and width with the nave and aisles. The great transept has a nave towards the east: attached to the western side of this transept is a gallilee, or grand porch; and on the southern side of the eastern aisle are two oratories, or private chapels; while the northern side has one of nearly similar shape and character. Branching from the northern side are the cloisters, which communicate with the chapter-house. The church is ornamented with three towers: one at the centre, and two at the western end: these are lofty, and are decorated with varied tracery, pillars, pilasters, windows, &c. The dimensions of the whole structure, according to the accurate measurements of Mr. T. Espin of Louth, are as follow: the height of the two western towers 180 feet. Previous to the year 1808, each of these was surmounted by a central spire 101 feet high. The great tower in the centre of the church, from the top of the corner pinnacle to the ground, is 300 feet; its width 53 feet. Exterior length of the church, with its buttresses, 524 feet; exterior length, 482 feet; width of western front, 174 feet; exterior length of great transept, 250 feet; interior, 222; width, 66; the lesser or eastern transept 170 feet in length, 44 in width, including the side chapels; width of the cathedral, 80 feet; height of the vaulting of the nave, 80 feet. The chapter-house is a decagon, and measures, interior diameter, 60 feet 6 inches. The cloisters measure 118 feet on the north and south sides, and 91 on the eastern and western sides. The grand western front, wherein the greatest variety of styles prevails, is certainly the workmanship of three, if not more, distinct and distant eras. This portion of the fabric consists of a large square-shaped façade; the whole of which is decorated with door-ways, windows, arcades, niches, &c. It has a pediment in the centre, and two octangular stair-case turrets at the extreme angles, surmounted by plain spire-shaped pinnacles. The upper transept and the choir appear the next in point of date. These are in the sharp-pointed style; and their architecture is very irregular, having pillars with detached shafts of Purbeck marble, in different forms, but all very light: those on the sides of the choir have been strengthened. The vaulting is generally simple; the ribs of a few groins only have a filleted moulding. A double row of arches or arcades, one placed before the other, is continued round the inside of the aisles, beneath the lower tier of windows. The windows, which are lofty and narrow, are placed two or three together; the greater buttresses in front are ornamented in a singular manner with detached shafts, terminating in rich foliage. This part of the fabric was probably built by bishop St. Hugh. The great transept, the gallilee porch,

and the vestry, are nearly of the same, but in a later style. The vestry is vaulted, the groining having strong ribs; and beneath it is a crypt with groins, converging into pointed arches. The nave and central tower were next rebuilt, probably begun by bishop Hugh de Welles, as the style of their architecture is that of the latter part of the reign of John, or the beginning of Henry III. Part of the great tower was erected by bishop Grosthead, who finished the additions which had been made to the old west front. The part extending from the smaller transept to the east end appears to have been built by bishops Gravesend, Sutton, and D'Alderby, about the conclusion of the thirteenth, or commencement of the fourteenth century. The latter prelate built the upper story of the rood tower, and added a lofty spire, which was constructed of timber, and covered with lead. This was blown down in a violent storm in the year 1547; and the damages then sustained were not wholly repaired till 1775. That nothing might be wanting to render this church as splendid in its furniture as it was elegant in its workmanship, it received the most lavish donations. So sumptuously was it supplied with rich shrines, jewels, &c. that, Dugdale informs us, Henry VIII. took away 2621 ounces of gold, and 4285 ounces of silver, besides precious stones of great value. This cathedral had formerly a great number of costly sepulchres and monumental records: of many, not a vestige remains; nor are the places known where they stood. At the Reformation, what the ravages of time had left, the zealots pulled down or defaced: so that, at the close of the year 1548, there was scarcely a perfect tomb remaining. Among the illustrious persons who were buried here, and had monuments erected to their memory, were Catherine Swinford, wife of John of Gaunt, duke of Lancaster; Joan, countess of Westmoreland, their daughter; and Bartholomew, lord Burghersh, brother to the bishop of that name. Many of the bishops were interred here.

On the north side of, and connected with, the cathedral are the cloisters, of which only three sides remain in the original state. Attached to the eastern side is the chapter-house, a lofty elegant structure. It forms a decagon, the groined roof of which is supported by an umbilical pillar, consisting of a circular shaft, with ten small fluted columns attached to it; having a band in the centre, with foliated capitals. One of the ten sides forms the entrance: in the other sides are nine windows, having pointed arches with two lights each. Over the north side of the cloisters is the library, which contains a large collection of books, and some curious specimens of Roman antiquities. It was built by dean Honeywood.

Besides monasteries, nunneries, and other edifices for pious uses, Lincoln had formerly more than fifty churches. Eleven only, exclusive of the cathedral, now remain; and scarcely any of them merit a particular description. Those most worthy of notice are, St. Bennet's, St. Mary de Wigford's, and St. Peter's at Gowts: these have lofty square towers in the Norman style. St. Peter's is a very ancient structure, and appears to have been the chapel of some religious house, of which the remains are extant. The places of worship for the different denominations of Dissenters, are, one for Roman Catholics, one for Independent Baptists, one for Presbyterians, and one for Methodists.

The number of parishes within the city is twelve, which, with the four townships within its jurisdiction, make sixteen. These, according to the government survey in the year 1800, contained 1574 houses, which were inhabited by 7398 persons. Many of the houses are old, but there are some very good buildings, both upon and below the hill. The city

LINCOLN.

has of late been considerably improved, by making a new road, paving the footways, and erecting a new market place.

Lincoln has an extensive trade in corn and wool, of which great quantities are exported into Yorkshire, by vessels which obtain a back freightage of coals and other necessary articles for the use of the interior. This city is a county of itself, having subject to it four townships in the vicinity, Bracebridge, Canwick, Branton, and Waddington, called the "Liberty of Lincoln." This privilege was conferred in the third year of George I.; and in official acts it is denominated, "The City and County of the City of Lincoln." Its viscountial jurisdiction extends twenty miles round; a privilege unequalled by that of any city in the kingdom. In the 26th year of Edward I. A. D. 1298, Wilhelmus Disney and Johannes Marmion were summoned to parliament as its first representatives. In the history of the boroughs of Great Britain, it is said, "This city had summons, with London and York, to send members to parliament, the forty-ninth of Henry III." The right of election is considered to be in the freemen, and the number of voters is about eleven hundred. The political influence, though by no means absolute, is possessed by Lord Delaval, who has a seat at Doddington, in the neighbourhood. The civil government of Lincoln is vested in a corporation, consisting of a mayor, twelve aldermen, two sheriffs, twenty-eight common-councilmen, and four chamberlains; with a recorder, deputy recorder, steward of the courts of borough-mote, a town-clerk, four coroners, four sergeants of the key, or bailiffs, and other inferior officers. The city was incorporated so early as the seventh year of Edward II.; Henry Beil being then the first mayor. Leland, in his description of Lincoln, enumerates five "Gates in the waulles of the citie," and observes, "It is easy to be perceived, that the towne of Lincoln hath been notably builded at three tymes."

Of the castle, built by the Conqueror, little now remains; and the area is occupied by buildings appropriated to uses of the municipal power. The few remaining vestiges convey the same idea of original Norman architecture as that of York, erected nearly at the same period. The keep was not included, but stood half without and half within the castle wall, which ascended up the slopes of the hill, and joined the great tower. This being situated on a high artificial mount, it was equally inaccessible from within or without the castle area. It was nearly round, and covered the summit of the mount. The walls are above seven feet in thickness. In a corner of the area is a curious small building, appearing on the outside like a tower, called Cob's hall; which Mr. King thinks was originally used as a chapel.

Few places in the kingdom exhibit so many ancient remains as Lincoln. Saxon, Norman, and pointed arches; and door-ways with turrets, walls, mullions of windows, and other fragments of old dilapidated buildings, appear in every direction. Its numerous churches and religious houses, the vestiges of which occasionally meet the eye of the enquiring traveller, are highly interesting to the antiquary, as tending to illustrate the progress of the arts, and the history of past ages. The Mint-wall, mentioned by Mr. Gough, is still remaining, and forms part of the inclosure of a garden.

Chequer gate, at the west end of the cathedral, had two gate-houses; the western one has been recently taken down; the remaining one, to the east, has three gateways, and two turrets between them. In Eastgate-street are two very ancient gateways, one of which is nearly entire. At the bottom of

the town, near Brayford water, are remains of a fort, called Lucy-tower. In the minster yard is a large gateway, with grooves for a portcullis. A large oblong building, in Broadgate-street, was appropriated to the Grey friars, and still displays much of its ancient architecture: part of this edifice is now used as a free-school, and the other part as a library. The deanery-house was founded by dean, afterwards bishop, Gravefend, in 1254. The vicar's college, called the Old Vicars, formed a quadrangle, of which there remain only four good houses, inhabited by the vicars. The bishop's palace, on the south side of the hill, which, from being situated near the summit, Leland described as "hanging in declivity," was built by bishop Chesney, to whom the site was granted by king Henry II. It was enlarged by succeeding prelates, and was scarcely exceeded in grandeur by any of our ancient castles. Adjoining to St. Andrew's church-yard formerly stood the palace of the celebrated John of Gaunt. Opposite to this house is a large building, called John of Gaunt's stables. It was a large structure, in the Norman style, and formerly consisted of a quadrangle, enclosing a spacious area; of which only the north and west fronts remain. The Jew's house, on the side of the hill, is an object of great curiosity: it is singularly ornamented in front, and some of its mouldings are similar to those found the west doors of the cathedral; in the centre of the front is a semicircular arched door-way, with a projecting pilaster. This house was possessed by Belafet de Wallingford, a Jewess, who was hanged for clipping in the 18th of Edward I. The Stone-bow, a large tower-gateway, crossing the High-street, is said to have been erected in the reign of Richard II.; but the style indicates a later date. The High-bridge, over the main stream of the Witham, consisting of one arch, is considered to be at least five hundred years old. Formerly here were two grammar schools, one in the clole, the other in the city: they were united in 1583. The principal modern buildings are, the market house, erected 1736; the blue-coat-school, on the plan of Christ's-hospital, London; the county hospital; the county gaol, constructed on the plan of Mr. Howard for solitary confinement; two assembly rooms, and a small theatre.

Among the distinguished natives of Lincoln was the late Dr. Willis, celebrated for his treatment of infancy, who died at an advanced age December 1807. *Beauties of England*, vol. ix. *The History of Lincoln*, 12mo. 1810.

LINCOLN, a maritime county of America, in the state of Maine, bounded N. by Kennebeck county, S. by the ocean, E. by Hancock county, and W. by that of Cumberland. The sea-coast extends from that part of Penobscot bay, opposite to Deer island eastward, to Cape Small-point westward. The sea-coast of the counties of Cumberland and Lincoln is 100 miles in extent, measured in a straight line, but said to be above 200 by the course of the waters. It abounds with safe and commodious harbours; and the whole shore is covered by a line of islands, among which vessels may generally anchor in safety. Across the country there is a water communication by lakes, ponds, and rivers, from the western to the eastern bounds; so that the productions of the country may be conveyed to the different seaports. The chief towns are Wicasset, Waldoborough, and Warren.—Also, a county of Upper Canada, divided into four ridings and 20 townships, containing about 6000 inhabitants, and furnishing five battalions of militia. It is said that 19 covered waggon brought families to settle in the vicinity of the county of Lincoln, in June 1799.—Also, a county of Morgan district, North Carolina, containing 12,568 inhabitants, of whom 1479 are slaves. In this county are mineral springs and mines of iron. The manu-

facture

facture of iron is carried on in this county. The chief town is Lincolntown. —Alfo, a county of Georgia, formed in 1796, containing feven townships, and 4766 inhabitants, including 1433 flaves. —Alfo, a county of Kentucky, containing 8555 inhabitants, of whom 1750 were flaves. The road from Danville on Kentucky river paffes through fourth-wefterly, and over Cumberland mountain to Virginia. —Alfo, a town in Mercer county, Kentucky, on the road from Danville to Virginia; 12 miles S. E. of Danville. —Alfo, a township in Grafton county, New Hampshire, incorporated in 1764, and containing 41 inhabitants. —Alfo, a township in the N. E. part of Addison county, Vermont, containing 97 inhabitants. —Alfo, a township in Middlefex county, Maffachufetts, incorporated in 1754, and containing 756 inhabitants; 16 miles N. W. of Bolton.

LINCOLNSHIRE, a maritime county of England, is bounded on the N. by the river Humber, which feparates it from Yorkfhire; on the E. by the German ocean; on the S. by Cambridgefhire and Northamptonfhire; and on the W. by the counties of Rutland, Leicefter, Nottingham, and York. It is in length 77 miles, and about 48 in breadth; and contained, according to the return made to parliament in 1800, 42,489 houfes, inhabited by 208,557 perfons, viz. 102,445 males, and 106,112 females: 24,263 were flated to be employed in trade and manufacture; and 60,584 in agriculture. By a return to the houfe of lords in 1805, the area of this county is flated to be 2787 fquare ftatute miles, equal to 1,783,680 ftatute acres; the number of inhabitants on each fquare mile 75; and the total number of perfons 209,025. The total amount of the money raifed by the poor's rate in 1803 was 145,848*l.* at the rate of 3*s.* 7*d.* in the pound; and the grofs amount of the affeffment under the property tax of 1806 was 2,704,736*l.* The average of the deaths for ten years appears to be as 1 to 49½ of the population. Mr. Stone, in his view of the agriculture of this county, ellimates the number of acres at 1,893,100; of which he fuppofes there may be 473,000 acres of inclofed, marfh, and fen lands, 200,000 of commons, wafles, and unembanked fait marfhies, 268 000 of common fields, 25,000 of woodlands, and 927,120 of inclofed upland. Mr. Arthur Young flates the area of this county at 2888 fquare miles, or 1,848,320 acres; of which he fays, the wolds contain, 234,880; the heath 118,400; lowland 776,960; and mifcellaneous foils 718,080.

That part of Britain which is now called Lincolnfhire, was, anterior to the Roman conqueft, poffeffed by a clafs of Britons known by the name of Coritani. During the Roman dominion, this diftrict was included within the province of Britannia prima; and was interfefted by different roads, occupied by military ftations, and fome of its natural inconveniences removed by Roman fcience and induftry. The principal roads were the Britifh Ermin-ftreet, afterwards adopted by the Romans, and the Fofs-way. A great work of this county, generally attributed to the Romans, is the Car-dyke, a large canal or drain, which extends from the river Welland, on the fouthern fide of the county, to the river Witham, near Lincoln. Its channel, for nearly the whole of this courfe, an extent of upwards of forty miles, is fixty feet in width, and has a broad flat bank on each fide. This great canal receives from the hills all the draining and flowing waters, which take an eafterly courfe, and which, but for this Catchwater drain, as it is now appropriately called, would ferve to inundate the Fens. Several Roman coins have been found on the banks of this dyke. The whole of the prefent county is fuppofed to have been named by the Romans Lindum, and the principal ftation or town Lindem colonia.

During the Anglo-Saxon dominion in England, Lincolnfhire was incorporated within the kingdom of Mercia, which, according to an old chronicle quoted by Leland, was then divided into two provinces, north and fourth; and as the Trent was the line of feparation, the county of Lincoln conflituted a confiderable part of South Mercia. Crida was the frft Mercian fovereign, and began his reign in 586. At this time Mr. Turner, (History of the Anglo-Saxons,) fuppofed that the whole ifland was governed by eight Anglo-Saxon monarchs; whence it fhould rather be denominated an octarchy than an heptarchy. During the eftablifhment of thefe petty kingdoms, the Saxons were in conflant warfare with the Romanized Britons; and after thefe were fubdued, the former were repeatedly embroiled in conflicts with each other. In the midft of thefe civil commotions Chriftianity was introduced, and gradually made its progrefs through the ifland; giving a new turn to human purfuits, and diverting and engroffing the attention of the barbarous heathens. Peada, the fon of Penda, was the reigning monarch here, when this religion was accepted by the South Mercians: he founded a monaffery at Medenhamfted, now Peterborough. He was foon afterwards murdered, as fuppofed, by his wife. Edwin the Great, the frft Chriftian king of Northumberland, conquered the counties of Durham, Chefter, Lancaller, the Ifle of Man, and Anglefea, carried his arms fourthward over the Trent, and obtained all the province of Lindfey. Paulinus, who converted him to Chriftianity, preached the gofpel wherever that king's power extended. He built the cathedra of Southwell, a little weft of Newark, baptized many thoufands in the river Trent, near to Tiofulingacefter, and converted Blecca, the governor of Lincoln. This was about the year 630. The learned and pious Alkfrid kept his court at Stamford in 658. After the death of Ofwy, king of Northumberland, Egfrid, his fon, invaded Wulfere, and wrestled from him the whole province of Lindfey in Lincolnfhire. In 677 he erected the epifcopal fee of Sidnacefter, in favour of Eadhed, who had been chaplain to his brother Alkfrid, king of Deira. In 683, Eadhed removed to Ripon, where he remained till his death. The fourth Mercian kingdom and bifhop's fee being thus eftablifhed, but few public events are recorded, till the incurfion of the Danes, who, in the year 870, laid wafte great part of Lincolnfhire, and burned the monafferies of Bardney, Croyland, and Medenhamfted, putting all the monks to the fword. After the defeat of the Danes by Alfred, the fovereignty of Mercia fell into his power. He did not, however, afcendly incorporate it with Weflex, but difcontinued its regal honours; and during the reign of Edward the Elder, it was found neceffary to conftitute and fortify feveral places on the borders of Mercia joining Northumbria, particularly on the banks of the Humber. Mercia was foon afterwards annexed to Weflex, but fome places were ftill held by the Danes; among thefe were the towns of Stamford and Lincoln, even fo late as 941, when Edmund the Elder expelled them hence.

The maritime counties of England being more directly expofed to attack from invading armies and piratical plunderers; and in the early part of our civil eftablifhments, being more populous than the midland country, were therefore frequently expofed to the conflicts of warfare; and hence it is found that thefe diftricts abounded with military works and caftles or caftellated manfions. Befides the permanent ftations of the Romans in Lincolnfhire, they threw up caftrematations in different places; to guard the vallies, protect the great roads, and defend the mouths of the rivers. In the continued wars between the Anglo-Saxon kingdoms, thefe were again occupied by the contending parties; and after

LINCOLNSHIRE.

after the Norman conquest, some of the most commanding were adopted by the conqueror's captains and barons, and then became heads of extensive lordships. To describe or discriminate them, is, and ever will be, impossible; for documents are wanting, and the innovations of the latter occupiers generally obliterated or annihilated all traces of their predecessors. Exclusive of the Roman stations, there are notices or remains of the following fortifications in this county. Encampments at or near Brocklesby, Hibberton, Broughton, Roxby, Winterton cliffs, Aulkborough, Yarborough, South Ormsby, Burwell, Stamford, Castle-hill near Gainsborough, Winterton, Humington, Ingoldby, Castle Carleton, Burgh, Brough, north of Causton, Barrow. Castles, or remains at Horncastle, Tattershall, a noble remain, Bourne, only earth-works remaining, Caistor, Somerton, Moor Tower, Stamford, Scrivelsby, Torksey, a fine remain, Sleaford, only earth-works, Bollingbrook, Lincoln, with walls and gates, Folkingham, with large fosse, Kyme tower, and Hufley tower, near Boston, Pinchbeck, a moated mansion, Bitlam.

According to the best authorities, the episcopal see was established at Lincoln towards the close of the eleventh century, previous to which era, the diocese had consisted of the two Anglo-Saxon sees of Dorchester, now a village in Oxfordshire, and Sidnacester a place bordering on the river Trent. The diocese of Lincoln is the largest in the whole kingdom, notwithstanding those of Oxford, Peterborough, and Ely, have been taken from it. It comprehends the counties of Lincoln, Leicester, Huntingdon, Bedford, and Buckingham, excepting the parishes of Monks, Risborough, and Halton, which are peculiars of Canterbury; and Abbot's, Aston, and Winslow, (which, with fifteen other parishes that are in Hertfordshire, and were taken thence, being made of exempt jurisdiction, and appropriated to the abbey of St. Albans, became, on the dissolution of that monastery in 1541, part of the diocese of London.) The see also retains the greater part of Hertfordshire, and several parishes in the counties of Oxford, Rutland, and Northampton. The whole diocese is divided into six archdeaconries; these are subdivided into fifty-two deaneries; the number of parishes is stated by Browne Willis to be, including donatives and chapels, 1517, of which 577 are impropriated; and the clergy's yearly tenths in this very extensive jurisdiction 1751*l.* 14*s.* 6*d.* Camden says there are 630 parishes in this county. The monasteries, hospitals, &c. connected with the cathedral and its ecclesiastical establishment, were very numerous, and some of very extensive influence.

The ecclesiastical architecture of Lincolnshire has long been justly celebrated for its magnificence; and its numerous churches have been the subjects of admiration. It is remarkable that the most splendid edifices which adorn this district, were erected chiefly in its lowest and most fenny situations, where all communication must formerly have been, and even to this day is extremely difficult. The ecclesiastical edifices in the division of Lindsey, excepting the cathedral of Lincoln, are in general inferior to those in Kesteven and Holland; but in the north-eastern part of this division, which is bounded by the German ocean to the east, and the highlands, called the Wolds, to the west, there are several churches, displaying much elegance in their architecture, and built of excellent materials. The division of Kesteven abounds with churches splendid both in their plans and decorations. In the central part, the greater proportion of them is adorned with lofty spires; while many of those in the northern and southern extremities present handsome towers, frequently divided into three or four distinct stories,

and formed of excellent materials and masonry. The date of the churches in this division, with the exception of those of Sempringham and St. Leonard Stamford, is, in few instances, earlier than the thirteenth century. It is principally in the division of Holland that Lincolnshire boasts of superior excellence in ecclesiastical architecture; and it is really surprising that so many fine monastic buildings, and sacred edifices, should have been erected in a country so inconvenient for travelling, so unpleasant to the eye, and so uncongenial with the common comforts of life; yet in this fenny and swampy district, are the churches of Boston, Gosberton, Pinchbeck, Spalding, Holbeach, Gedney, Long-Sutton, Croyland, and many others, which have a just claim to universal admiration. The character and plan of the churches in this division vary in different parts. Some are cruciform; many have spires in common with those of Kesteven; while embattled towers at the west end form the principal feature of the remainder. Of the splendid church at Croyland, only a small portion of the original structure now remains; but sufficient to shew that in its entire state, it was not inferior to any of our cathedrals, either in size or architectural ornament. The stone employed in the erection of the edifices of this district is universally found to be of an excellent and durable species, still retaining at the distance, in many instances, of six or seven centuries, its original face and firmness.

This county is more noted for its religious than for its civil architecture. Though of great extent, it contains but few mansions of consequence, grandeur, or elegance, and those are chiefly of modern erection. The following are the principal; Grimsthorpe castle; the seat of the duke of Ancaster-Nocton; earl of Buckinghamshire—Glentworth; earl of Scarborough—Broklesby; lord Yarborough—Belton; lord Brownlow—Redbourn; lord William Beauchamp—Burton; lord Monson—Doddington; lord Delaval—Bloxholm; Hon. colonel Manners—Manby; Hon. Charles Anderson Pelham—Revesby abbey; sir Joseph Banks, bart.

Lincolnshire, and the counties of Essex, Cambridge, and Norfolk, have been generally described as particularly unfavourable to health; and from their contiguity to the sea, with the numerous fens, meres, brooks, &c. with which they abound, are commonly stigmatized as producing pellilential climates, only calculated to excite agues, cramps, and rheumatisms. These general maxims, though frequently originating in facts, are too often perverted, or extended beyond due bounds. Lincolnshire may be said to be in this predicament; for its name is commonly associated with fens, flatness and bogs. Those who reside in, or have travelled over it, are enabled to appreciate and define its character. Arthur Young has pointed out and described many features and places in this county, that may be referred to as partaking of the beautiful and picturesque:—"About Belton," he says, "are fine views from the tower on Belmont; Lyra and the Norfolk cliffs are visible, Nottingham castle also, the vale of Belvoir, &c. And in going by the Cliff towns to Lincoln, there are many fine views. From Fulibeck to Leadenham, especially at the latter place, there is a most rich prospect over the vale of the Trent to the distant lands that bound it. These views, over an extensive vale, are striking, and of the same features as those from the cliff-road to the north of Lincoln, to Kirton, where is a great view both east and west to the Wolds, and also to Nottinghamshire. Near Gainsborough there are very agreeable scenes; from the plantation of H. Dalton, of Knaith, and from the chateau battery of Mr. Hutton, of Burton, the view of the windings of the Trent, and the rich level plain of meadow, all alive with great herds of cattle, bounded

LINCOLNSHIRE.

bounded by distant hills of cultivation, are features of an agreeable country. But still more beautiful is that about Trentfall; from Sir John Sheffield's hanging wood, and the Rev. Mr. Sheffield's ornamented walk, following the cliff to Alkborough, where Mr. Goulton's beautiful grounds command a great view of the three rivers; as the soil is dry, the woods lofty, and the country various, this must be esteemed a noble scenery, and a perfect contrast to what Lincolnshire is often represented by those who have only seen the parts of it that are very different. The whole line of the Humber hence to Grimsby, when viewed from the higher wolds, presents an object that must be interesting to all. Thus, with the very great plantation of Lord Yarborough, are seen to much advantage, from that most beautiful building, the mausoleum at Brocklesby." Many other parts of the county might be pointed out as presenting in themselves, or commanding, interesting scenery. The country around Grantham, also in the vicinity of Louth, and that more particularly between Bourn and the former place, including the noble and spacious woods of Grimsthorpe, abound with that inequality of surface, that diversified interchange of hill and dale, wood and lawn, which constitute the picturesque and beautiful in natural scenery.

Lincolnshire may be said to present three great natural features, each of which has a specific and nearly uniform character. These are the wolds, heaths, and fens. The latter occupy the south-eastern side of the county, and though formerly a mere waste and perfectly sterile, have been, by means of drainage, &c. rendered subservient to agriculture; many parts indeed may be pronounced uncommonly fertile. On the sea coast, towards the north part of the county, this tract is narrow; near the Humber it contracts to a mere strip of land. The heaths, north and south of Lincoln, and the wolds, are calcareous hills, which, from their brows, command many fine views over the lower regions. The rest of the county is not equally discriminated, either by fertility or elevation. "The heath, now nearly inclosed," says Arthur Young, "is a tract of high country, a sort of back bone to the whole, in which the soil is a good sandy loam, but with clay enough in it to be slippery with wet, and tenacious under bad management; but excellent turnip and barley land, on a bed of lime-stones, at various depths, from six inches to several feet, commonly nine inches to eighteen. This hill slopes sharply to the west; the declivity of the same nature, but generally good; and this extends some distance in the flat vale, for the first line of villages, (built also as the soil lies in a longitudinal direction north and south.) The soil is rich loam, containing much pasture." Between Gainborough and Newark, for twenty five miles, is a large tract of flat sandy soil, the greater part of which has been inclosed, and partly drained. The soil of the Isle of Axholme may be said to be among the finest in England. It consists of black sandy loams, warp land, brown sand, and rich loams of a soapy and tenacious quality. The under stratum at Stacey, Belton, &c. is, in many places, an imperfect plaster stone. Respecting the general products of the county, the higher grounds are now mostly inclosed, and appropriated to tillage, and produce all sorts of grain. Some of the wolds, however, are not yet divided, but are devoted to sheep and rabbits. The lower lands that have been drained and inclosed, produce abundant crops of oats, hemp, flax, &c.

Lincolnshire has long been famous for a breed of fine horses; but the adjoining county of York has now the credit for rearing many that are actually bred in this county. In some districts great numbers of mares are kept for the sole purpose of breeding. In Holland Division almost every

farmer keeps some; and the number of colts reared is very great. The neat cattle of this county are described by Mr. Stone as being, for the greatest part, of a large sort, having great heads and short horns; stout in the bone, and deep in the belly; with short necks and fleshy quarters, narrow hips and chins, high in their rumps, and bare on the shoulders. The cows, he remarks, when fat, weigh from eight to nine hundred, and the oxen from ten to twelve hundred. The most profitable flock of the county appears to be sheep. Numbers are bred and fattened in this part of the kingdom. Large quantities of wool are thence obtained, to supply the demands of the neighbouring districts. It is a curious fact, that while so much has been said in commendation of the Leicestershire breed, the Lincolnshire, which is the same, should have been passed over in silence. Mr. Stone says, these sheep are not even varieties. The Lincolnshire, a large horned animal, adapted for the rich grazing and marsh land of the county; generally weighs well when fat, and bears a heavy fleece of coarse but long stapled wool; the weight, per fleece, is eight pounds and upwards. Mr. Young mentions a sheep sold at Smithfield, which clipped, the first year, 23lb. of wool, and in the second year, 22lb. Few manufactures are established in this county; but here are two objects of considerable merchandize, rabbits' fur, and goose feathers. These were formerly of great consequence, and furnished articles of extensive trade. From the system of inclosing, now so extensively adopted, both rabbits and geese are much diminished.

The rabbit warrens of this county were formerly much more extensive than at present, and were preferred on a principle of improvement; some being broken up for tillage, and others, which had been under till, being again laid down for this purpose. The soil of old warrens, by the rabbits continually stirring and ventilating the earth in burrowing, has been found incomparably better than lands of a like nature left in their original state. The fecundity of rabbits was a circumstance of no small consequence, when the skins of large well-chosen rabbits would produce 2s. 6d. or 3s. each: at that time they were used in making muffis, tippets, lining robes, &c.: the down was also employed in hats. As the skins constitute the principal profit of the proprietor, it becomes a primary object with him to attend to the breeding, killing, &c.: skins that are free from black spots on the inside are said to be in season. The trade is now on the decline, not only from the diminution in the value of the skins, but also from the means of conducting it becoming daily more circumscribed, it being now thought good husbandry to destroy the warrens, and apply the land to other uses. The number of warrens in this county has been greatly reduced, yet many thousand acres are still devoted to this kind of stock.

Many of what are called the fens, are in a state of waste, and serve for little other purpose than breeding and rearing geese, which are considered the fenman's treasure. They are a highly valuable flock, and live where, in the present state of those lands, nothing else will: they are very prolific, and the young quickly become saleable, or speedily contribute to increase the flock. The feathers are very valuable; and however trifling it may appear, the sale of quills alone amount, on a large flock, to a considerable sum. "During the breeding season," Mr. Gough says, "these birds are lodged in the same houses with the inhabitants, and even their very bed-chambers; in every apartment are three rows of coarse wicker pens, placed one above another; each bird has its separate lodge, divided from the other, which it keeps possession of during the time of sitting. A gozzard, or gooseherd, attends the flock, and twice a

day drives the whole to water, then brings them back to their habitation, helping those that live in the upper stories to their nests, without ever misplacing a single bird." The geese are usually plucked five times in the year: at Lady-day for quills and feathers, and again at Midsummer, Lammas, Michaelmas, and Martinmas. Goslings are not spared, as early plucking tends to increase the succeeding feathers. Mr. Young states, that "the feathers of a dead goose are worth sixpence, three giving a pound; but plucking alive does not yield more than three-pence a head *per annum*. Some wing them only once every quarter, taking ten feathers from each goose, which sell at five shillings a thousand. Plucked geese pay, in feathers, one shilling a head in Wildmore Fen." The common mode of plucking live geese is considered a barbarous custom; but it has, perhaps, prevailed ever since feather beds came into general use. The mere plucking is said to hurt the bird but little, as the owners are careful not to pull before the feathers are ripe, that is, just ready to fall: if forced from the skin sooner they are of inferior value.

The general improvements that have been effected in this county within the last twenty years, and that are now gradually making, have co-operated to alter the general appearance, the agriculture, climate, &c. so materially, that the surface has assumed a new aspect, the value of land is greatly increased, the means of social and commercial communication have been facilitated, and the comforts of domestic life greatly promoted. Yet there is still scope for material improvements: for the roads, in many parts of the county, are in a very bad state; and the traveller has not advantages adequate to the tolls levied on him. In the vicinity of Boston, Spalding, and Louth, the commissioners have commenced a plan for forming firm and substantial roads. This is mostly done by laying shingles, brought from the Norfolk coast, in the centre of the road, and mixing them with the silt of the place.

The wolds extend from Spilsby, in a north-westerly direction, for about 40 miles to Barton, near the Humber. They are, on an average, nearly eight miles in breadth, of sand and sandy loam, upon flinty loam, with a substratum of chalk. Beneath this line lies an extensive tract of land at the foot of the wolds, called the marsh, which is secured from the encroachments of the sea by embankments, and is agriculturally divided into north and south marshes by a difference in the soil.

The fens of this county form one of its most prominent features. They consist of lands which, at some distant period, have been inundated by the sea, and by human art have been recovered from it. In the summer they exhibit immense tracts, chiefly of grazing land, intersected by deep ditches, called droves, which serve both for fences and drains. These are accompanied generally by parallel banks, upon which the roads pass, and are intended to keep the waters, in flood time, from overflowing the adjacent lands. They not only communicate with each other, but also with larger canals, called dykes and drains, which, in some instances, are navigable for boats and barges. At the lower end of these are sluices, guarded by gates, termed gowts. During the summer, numerous flocks and herds are seen grazing over this monotonous scene, and many of the pastures afford a luxuriant herbage: but in the winter, or in the autumn, if it should prove wet, the aspect is changed; the cattle quickly disappear, and the eye must pass over thousands of acres of water or ice, before it can find an object on which to rest. Several causes combine to produce this drowning of the lands. Many of the fens lie below the level of the sea; some are lower than the beds of the rivers; and all are beneath the high-water mark of their respective

drains. The substratum of the fens is silt, or sea-sand, which is a well-known conductor of water. Through this, when the drains are full, the sea-water filters; and, unable to pass by the drains, rises on the surface, and is known by the name of *foak*. Dugdale was of opinion, that there was a time when these parts were not inundated. In his history of embanking, he observes, that the isle of Axholme, though for many ages it hath been a fenny tract, was not anciently so, but was originally a *woody* country, not annoyed with these inundations, as is evident from the great numbers of trees which had been found in the moor. The same author, speaking of the great level, gives his opinion that it was formerly firm and dry land, neither annoyed with stagnation of fresh waters, nor inundations from the sea; and this he supposes was the case of the fens in Lincolnshire, and the adjoining counties: for it is an established fact, that large timber trees will not thrive in watery lands, and such have been found lying in the earth abundantly in this country.

The principal rivers which either rise in the county, pass through it, or are connected with it, are the Trent, the Ancholme, the Witham, the Welland, and the Glen. The Trent, though not properly a river of this county, forms the boundary of it on the north-western side, from the village of North Cliford to that of Stockworth; whence it constitutes the eastern boundary of the isle of Axholme: it thence flows to Aldborough, and having received the Dun and the Ouse, mingles its waters with the Humber. From Gainsborough, where it is crossed by a handsome bridge, it is navigable for coals, corn, and various articles of commerce. The Ancholme is a small river, rising in the wolds, near Market-Raish, whence it is navigable to the Humber, into which it falls some miles below the junction of the Trent. The Welland has its source near Sibbertoft, in Northamptonshire; and being increased by numerous streams, passes Market-Deeping; where, entering the fens, it leaves a portion of its waters and sludge, which it had accumulated in its previous passage through the rich lands of Northamptonshire, Leicestershire, and Rutlandshire. It afterwards meets the contributory Glen, and empties itself into Foss-dyke-Wash, east of Boston. The Witham, which is completely a river of this county, derives its origin near South-Witham; and thence flows almost due north, through the park of Ealton, and to Great Ponton. It preceeds through a wide valley to Lincoln: continuing its course to Boston, it unites its waters with the sea at a place called Boston-Deeps. Much of the present bed of the river, from Boston upwards, is a new cut, made for the purpose of widening the channel, rendering it more commodious for navigation, and better adapted to receive and carry off the water of the contiguous fens. These rivers, with those of the Grant, Ouse, and Nene, in the adjacent counties, from the obstructions they meet in delivering their waters to the ocean, form one great cause of inundating so large a portion of valuable land. In viewing the various inlets of the sea, it is surprising to observe the immense quantity of sand and sludge which is continually depositing on the shore. This is owing to the nature of the tides, which, from the form of the channel, flow with more violence than they ebb. Hence the mouths of the rivers are choked up, and the descending waters are thrown back on the low-lands. The great bay, or estuary, into which the different rivers, passing through the fens, are emptied, is very shallow, and full of shifting sands and silt.

That this district was thus flooded at a very remote period, is evident from the plans of embanking and draining which the Romans adopted, in order to counteract the mischievous

effects of such inundations. Since their departure, much has been done at various times for the improvement of the fen country; and an immense expence has been occasionally, and is still annually, incurred, to prevent the encroachment of the water, and to ameliorate the soil. A very brief notice of these endeavours will tend to give some idea of the country, and to illustrate those periods of history. Deeping Fen, on the banks of the Welland, appears to have received the earliest attention: for, at the beginning of Edward the Confessor's reign, (as Ingulphus relates,) a road was made across it by Evesham, formerly a monk of Peterborough, but at that time bishop of Dunelm. In the time of the Conqueror, Richard de Fines, the king's chamberlain, inclosed this part of the fen-country from the chapel of St. Guthlake to Cardyke, and to Chivelake near Crummore; excluding the river Welland by a large and extensive bank of earth. The Fes-Dyke is an artificial trench, extending about seven miles in length, from the great marsh near the city of Lincoln to the river Trent in the vicinity of Torksey. This was made or materially altered by king Henry I. in the year 1121, for the purpose of magnifying, and for making a general drain for the adjacent level. From its passing through such a flat country, the water could have but a slow current, whereby it became unnavigable, and the accumulation of mud, so that it was soon found necessary to cleanse it. Of the marshes on the river Ancholme, the first account on record is the 16th of Edward I. In succeeding reigns, various statutes were enacted for rendering effectual the drainage of this part of the country. The island of Axholme, though now containing some of the richest land in the kingdom, was formerly one continued fen, occasioned by the silt thrown up the Trent with the tides of the Humber. This obstructing the free passage of the Dun and the Idle, forced back their waters over the circumjacent lands, so that the higher central parts formed an island, which appellation they still retain. In the first of Edward III., and in several succeeding reigns, commissions were granted for repairing the banks and ditches, as they fell to decay. Early in Charles I.'s reign, that great work was commenced, which embraced not only the marshes of Axholme, but of all the adjacent fens, called Dikefmarsh and Hatfield chase, in the county of York. These comprehended an extent of lands which were not only drowned in winter, but even in summer were so deeply covered with water, that boats could navigate over 60,000 acres. It is traditionally affirmed that large vessels could sail up the river Witham from Boston to Lincoln; and from the ribs, timbers, &c. of ships, that have been frequently found near it, the tradition seems to be justified. At present, it is only adapted for barges, and the flow of the current is so small, that it does not cleanse the bed of the river. The first notice of the inconveniences arising from the obstruction of its waters, appears in the sixth year of Edward III., when commissioners were appointed for surveying the same. In consequence of their report, and of various surveys and presentations in different reigns, successive resolutions were made for restraining the waters within due bounds, and for clearing the land-floods specially to the sea. But in the last reign of Henry VIII., more effectual measures were thought necessary to be adopted for restoring the country; and an able engineer, Mayhew Hake, of Goxburgh in Flanders, was invited over to put it into execution. It was accordingly covenanted between him and the king's commissioners, that the said Mayhew Hake should bring with him from Flanders fourteen masons, and four labourers, to make him a proper sluice and dam near the town of Boston, sufficient for its future safeguard. For which they were to be remunerated as follows: Mayhew

Hake, for himself and man, per diem 4s.; masons and stone-layers, per week, 5s.; labourers, per week, 4s. The said Mayhew Hake to receive 50*l.* more on the completion of the work.—Should any more workmen be necessary they should be provided at the expence of the inhabitants of Boston, and the lord of Holland and Kesteven. To the north and north-east of the Witham, are the large fenney tracts called Wildmore Fen, West Fen, and East Fen, in the latter of which, it appears by a writ, 41 Elizabeth, 50,000 acres were drowned. A plan is now executing under the direction of that very scientific and able engineer Mr. John Rennie, by which these three fens will be effectually drained, and the lowlands of this part of the county be rendered productive and profitable.

Lincolnshire consists of three great divisions; Holland, Kesteven, and Lindsey; which are subdivided into 32 hundreds, wapentakes, and tokes; containing in the whole one city, 31 market-towns, 657 villages. Twelve members are returned to parliament: two for the shire, two for the city, and two from each of the boroughs of Boston, Grantham, Great Grimsby, and Stamford. Spalding and Wainfleet were represented in the eleventh year of Edward III. This county, from its extent and opulence, is not under the influence of any individual; and in contested elections the freedom of the people is not so liable to corruption as in smaller counties and properly boroughs. *Beauties of England and Wales*, vol. ix. *Stone's Agricultural Survey of Lincolnshire*. *Young's Ditto*.

LINCOLNTOWN, a post-town of America, in North Carolina, and capital of Lincoln county, containing about 35 or 40 houses, a court-house, gaol, and church; 46 miles from Morgantown.

LINCOLNVILLE, a town of Hancock county, in the State of Maine, on the W. side of Penobscot bay; 12 miles from Belfast.

LINCOLNIA, in *Botany*, a name given by Linnaeus, but of whose origin or derivation we are unable to trace any thing.—*Linna. Mant.* 147. *Schreb.* 1770. *Walp. Syl. Pl.* v. 1. 126. *Juss.* 412. *Char. and order*, *Pentandria Digynia*. *Nat. Ord.* *Incerte sedis*, *Juss.*

Gen. Ch. Cal. Perianth inferior, of four ovate permanent leaves, the inferior opposite pair shorter. *Carp.* Petals five, imbricate, reflex, erect. Nectary a cavity in-puffed at the base of the petals, surrounded below by a margin. *Stam.* Filaments five, awl-shaped, slender, erect, of middling length; anthers obuse, arrow-shaped, bending towards the base of each lobe. *Pist.* Germen half inferior with respect to the corolla, but superior with respect to the calyx; styles two, thread-shaped, striated; stigma simple. *Pist.* Capsule of two cells. *Seeds* two?

Linnaeus observes that if the perianth may be taken for bractæes, the flower is altogether superior, but this does not seem correct.

Ess. Ch. Petals five, having each a honey-bearing cavity at their base. Capsule of two cells, half inferior.

1. *L. alcyonoides* *Michx.* *M. t.* 216. *Syst. Vegr. ed.* 14. 261.—A native of mountainous watery places at the Cape of Good Hope. This is a *herb* furnished with wand-like determinate *branches*, furnished with the bases of the fallen leaves, as in the first tribe. *Leaves* feathered, or somewhat whorled, about five or six in a whorl, a most sessile, linear, triangular, channelled, rigid, shining, appearing curiously granulated under a microscope, 20 inch long, rough at the angles, the upper ones fimbriate. *Flowers* about the tops of the branches, lateral, sessile, the length of the leaves, permanent, flesh-coloured, or white.

LINCTUS, a form of medicine, the same as *lambitus*, *lobach*, and *celegma*.

LINDA, in *Geography*, a small island in the Indian sea, near the coast of Africa, at the mouth of the Zambesi.

LINDAHL, a town of Norway; 140 miles N. of Christiania.

LINDANUS, **WILLIAM**, in *Biography*, a celebrated Dutch divine, was born at Dort, in Holland, in the year 1525. He pursued his academic studies at Louvain, and afterwards went to France to perfect himself in the Greek and Hebrew languages. Having returned to Louvain, he was ordained a priest, and admitted a licentiate in divinity. This was in the year 1552, and in the following year he undertook the office of lecturer on the sacred scriptures at Dilligen, which post he filled for three years with high reputation. He took his degree of D.D. in 1559, after which he was appointed dean of the Hague; counsellor to the king; vicar to the bishop of Utrecht, and inquisitor of the faith within the same ecclesiastical jurisdiction. On account of his great zeal in the latter office, the duties of which he performed with much severity, he was nominated, by the bigotted Philip II. of Spain, to the bishopric of Ruremond. In 1568 he went to Rome, and was received by pope Gregory XIII. and the cardinals with singular marks of respect and esteem. On his return he exercised the functions of a Christian bishop in a very honourable manner, applying the revenues of his see to the relief of the indigent, and visiting every part of his diocese for the purpose of personally comforting, instructing, and assisting those who stood in need of temporal or spiritual aid. After a second journey to Rome, he was appointed, in 1588, to the bishopric of Ghent, an office which he held but three months, when he died in the sixty-third year of his age. He was reckoned a very learned man and an able divine. His writings are numerous, consisting of Polemical treatises; Paraphrases on many of the Psalms, and the Psalter, illustrated with Greek and Hebrew texts: but his most valued publication is entitled "*Panoplia Evangelica*." Moreri.

LINDAR, in *Geography*, a town of Itria; 5 miles N.E. of Mittenburg.

LINDAU, an imperial city of Germany, seated on an island in the lake of Constance, and communicating with the continent by means of a bridge. The island is so divided by an arm of the lake, as to form another smaller island, which is separated from the city, and consists of vineyards and garden enclosed within a wall. Lindau, from its peculiar situation, has been called the Venice of Swabia. Most of the burghers are Lutherans. This city contains, besides a parish church dedicated to St. Stephen, a well-endowed hospital, and a grammar-school. The castle, and Heyden Maur, or Heathen wall, as it is called, are reckoned Roman works; the latter being ascribed to Tiberius Nero, and the former to Constantinus Chlorus, during their encampments here, in their expeditions against the Vindelici and Alemanni. It is supposed that near this castle formerly stood a church, and that the little church of St. Peter here was built on the first introduction of Christianity into this country. The territory of Lindau comprehends 14 villages; 19 miles E. of Constance. N. lat. 47° 28'. E. long. 10° 35'.—Also, a town and castle of Hungary; 17 miles N.N.W. of Chakathurn.—Also, a town of Westphalia, in the territory of Bielefeld, situated on the Rhine; 12 miles N.W. of Duderstadt.—Also, a town of Germany, in the principality of Anhalt Zerbst; 5 miles N. of Zerbst.—Also, a town of Germany, in the principality of Bayreuth; 8 miles N.W. of Bayreuth.

LINDE, or **LINDENBERG**, a town of Sweden, in Westmanland, situated between two lakes; built by queen Chris-

tina in 1644; near it is a medicinal spring; 85 miles W.N.W. of Stockholm. N. lat. 59° 35'. E. long. 14° 56'.

LINDEAL, a town of Hindooostan, in the circle of Cuddana; 25 miles N. of Gandicotta.

LINDECK, a town of the duchy of Silesia; 8 miles N. of Gilly.

LINDEN, a town of Germany, in the principality of Culmbach; 6 miles N. of Neustadt.

LINDENAU, a town of Prussia, in the palatinate of Thorn; 20 miles N.E. of Culm.—Also, a town of Silesia, in the principality of Neisse; 6 miles N.W. of Patzschkau.

LINDENBERG, a town of Germany, in the principality of Bayreuth; 9 miles E.S.E. of Bayreuth.

LINDENBRUCH, **FREDERIC**, in *Biography*, a learned philologist of the seventeenth century, was a native of Flanders, and died in 1638. He wrote notes on Terence, on the fragments of certain Latin poets, and on Ammianus Marcellinus. He also published "*Codex Legum-Antiquarum, seu Leges Wisigothorum, Burgundionum, Longobardorum, &c.*" which is esteemed a very curious work. Moreri.

LINDENFELS, in *Geography*, a town of Germany, in the palatinate of the Rhine; 14 miles N.N.E. of Mannheim.

LINDENHARDT, a town of Germany, in the principality of Bayreuth; 9 miles S. of Bayreuth.

LINDER, a town of Itria; 12 miles N.N.E. of Pedena.

LINDERA, in *Botany*, a name dedicated by Thunberg to the memory of John Linder, a physician at Stockholm, afterwards ennobled by the name of Linderholpe, who was born in the year 1678, and died in 1724. He was a celebrated Swedish botanist, and author of the *Flora Wilbergensis*, published at Stockholm in 1728. His inaugural thesis "*de Hesperidum pomis*" was published at Abo in 1702. About six years afterwards appeared his treatise "*de Venenis*" printed at Leyden; a posthumous edition of which was published at Leipzig in 1739, under the direction of M. Stenzelius. This is said to be a masterly dissertation on vegetable poisons.—He was also the author of an essay upon the colouring properties of several Swedish plants, particularly of some Lichens.—Thunb. Jap. 9. Nov. Gen. 64. Schreb. 232. Willd. Sp. Pl. v. 2. 230. Juss. 429. Lamarck Illustr. t. 263.—Class and order, *Hexandria Monogynia* Nat. Ord. *Uncaria sedis*, Juss.

Gen. Ch. Cal. Perianth none. Cor. Petals six, ovate, obtuse. Stam. Filaments six, many times shorter than the corolla; anthers very small. Pist. Germen superior, ovate, smooth; style erect, a little shorter than the corolla; stigmas two, reflexed. Peric. Capsule of two cells. Seeds . . .

Ess. Ch. Corolla of six petals. Capsule of two cells.

1. *L. umbellata*. Thunb. Japon. 145. t. 21. Linn. Syst. Veg. ed. 14. 339. (Kuro Noji; Kämpf. Amoen. 608.) Found on the mountains of Japan, flowering in April and May.—Stem shrubby, branched, spreading and weak. Branches alternate, zigzag, smooth. Leaves clustered at the extremity of the branches, on footstalks, oblong, acute, undivided, about an inch long; smooth and green above; hairy and puber beneath. Flowers terminal, in simple, many-flowered umbels.

Thunberg informs us that the Japanese make small brushes of the wood of this plant for cleaning the teeth.

LINDERA is also the name of a genus in Adanson's *Familles des Plantes*, v. 2. 499. by which he seems to have intended to honour Dr. Lindern. (See **LINDERIA**.) His plant appears to be a *Charophyllum*.

LINDERKREUZ, in *Geograph.*, a town of Saxony, in the circle of Neuladt; 8 miles N.W. of Weyda.

LINDERNIA, in *Botany*, so called by Allioni, in honour of Francis Balthazar von Lindern, a physician at Strasburg, who lived in the early part of the last century, and appears to have graduated at Jena, where his inaugural dissertation, "*de Vermibus*," was published in 1707.—As a botanist he is known from the following works, *Tournefortius Alfaticus*, published in 8vo. at Strasburg, in 1728, — and *Hortus Alfaticus*, in 1747. The latter contains an account of the plants growing in the province of Alfatia, and especially about Strasburg. Both the works are accompanied by a few plates.—Allion. Ped. v. 1. 57. Linn. Mant. 154. Schreb. 416. Willd. Sp. Pl. v. 3. 325. Mart. Mill. Dict. v. 3. Juss. 122. Brown. Prodr. Nov. Holl. 440. Lamarek Illustr. t. 522.—Class and order, *Didymia Angiospermia*. Nat. Ord. *Personate*, Linn. *Scrophulariæ*, Juss.

Gen. Ch. Cal. Perianth of five, deep linear, acute, equal, permanent divisions. Cor. of one petal, gaping, two-lipped; upper lip very short, concave, emarginate; lower erect, trifid, the middle segment rather larger. Stam. Filaments four, in pairs, the two upper ones simple, the two lower ascending, with a terminal, straight tooth; anthers twin, the lower ones as it were lateral. Pist. Germen superior, ovate; style thread-shaped; stigma emarginate. Peric. Capsule oval, of one cell and two valves. Seeds numerous. Recept. cylindrical.

Ess. Ch. Calyx deeply five-cleft. Corolla ringent, the upper lip very short. The two inferior stamens having a terminating tooth and a subterminal anther. Capsule of one cell.

1. *L. Pyxidaria*. Linn. Mant. 252. Allion. Misc. Taur. v. 3. 178. t. 5. Icon. Taur. v. 16 t. 84. (Capraria gratioides; Linn. Sp. Pl. 876. *Pyxidaria repens* annua; Lindern. Tournef. Alfatic. 156. t. 5. Hort. Alfatic. 269. *Gratiola floribus pedunculatis*; Gron. Virg. 3.)—Leaves oval, entire, sessile. Peduncles solitary.—Originally a native of Virginia, in spongy, inundated marshes, whence it was brought into Europe, and may at present be found in similar situations, in Alface and Piedmont, flowering in July and August.—Root annual. Stem smooth, square, brittle, occasionally branched and creeping. Leaves opposite, small, slightly notched, like those of *Anagallis*. Flowers axillary, solitary, of a pale blue colour.

2. *L. diandra*. Swartz. Prod. 92. Ind. Occ. 1058. (*Erinus procumbens*; Mill. Dict. n. 6.)—Leaves on footstalks, ovate or roundish, slightly serrated. Stem creeping.—A native of moist sand or clay in Hispaniola.—Root thread-shaped, with short fibres. Stem herbaceous, loosely spreading. Branches ascending, square, smooth. Leaves opposite, ribbed, scarcely veined. Flowers small.

3. *L. japonica*. Linn. Syst. Veg. ed. 14. 567. Thunb. Japon. 253.—Leaves obovate, toothed, the lower ones on footstalks. A native of Japan, where it flowers through the spring. Root annual. Stem herbaceous, branched, weak. Branches alternate, from an inch to a span in length. Radical leaves numerous; stem-leaves few, sessile, all obovate, obtuse, toothed, very slightly hairy. Flowers in clusters at the extremities of the branches.

These two species last described are said by the ingenious Mr. Brown, in his Prodrum to the Flora of New Holland, to be certainly different in genus from *L. Pyxidaria*. The same author describes the three following new species of *Lindernia*, all natives of the tropical part of New Holland, though he remarks that they do not altogether accord with the original character of this genus.

L. alfinoides. Leaves ovate, entire or slightly toothed; stem-leaves distant: floral-ones small. Tube of the corolla a little longer than the calyx. Stem erect.

L. scapigera. Leaves broad-ovate, nearly entire: lower ones crowded together: those of the stem few and small: floral leaves minute. Tube of the corolla twice as long as the calyx.

L. jubulata. Leaves linear-awl-shaped, entire. Found by the Rt. Hon. Sir Joseph Banks only.

LINDERUPOE, in *Geography*, a small island of Denmark, in the Little Belt, near the coast of Sleswick; 8 miles W.S.W. of Assens in the island of Funen.

LINDESNESS, or *the Naze*, a cape on the S. coast of Norway, in the North Sea, connected with the land by a very narrow isthmus. The cape projects into the sea about a Norway mile towards the S.W., and is about half a mile broad. The promontory is high, rocky, and barren, and has upon it twelve houses of peasants. N. lat. 58 1'. E. long. 7 12'.

LINDEWEISE, a town of Silesia, in the principality of Neisse; 11 miles S.E. of Neisse.

LINDISFARNE, or *Holy Island*, an island situated in the North Sea, opposite to the coast of that portion of Durham which lies between the river Tweed and the county of Northumberland, England. It was named by the Britons Inis-Mendicante. The appellation Holy Island was given to it by the English from being the residence of several of the primitive fathers of the Saxon church. The distance of this island from the Mainland is about two miles. It is easily accessible at low water to all kinds of conveyance, but the sands are dangerous to such persons as are unacquainted with them. The circumference of this island is about nine miles, and the number of acres contained in it 1020, nearly one-half of which are mere sand-banks. The other grounds are rather of a rich soil; but previous to the year 1792, when the common was inclosed, only 40 acres were in tillage. The rental increased between the years 1790 and 1797, from 320*l.* to 396*l.* The town is situated on the west corner, and in 1798 was inhabited by 379 persons, who were chiefly employed in fishing. From the names and ruins of several streets it is conjectured to have been at one period much more considerable than it now is. In the year 635 this place was made a bishop's see by king Oswald. Its first prelate was a Scotchman of the name of Aiden. The church, or monastery, originally consisted of timber and thatch. St. Cuthbert, the saint to whom it was dedicated, was buried here; but after the Danes began their depredations, the monks removed to Chester-le-Street, and carried the saint's body along with them. After their flight the invaders destroyed the building, which however seems to have been subsequently rebuilt, at least in part. Various detached portions of this edifice are still standing. Portions of the church constitute the principal ruins. The north and south walls of it are still almost entire, though much out of the perpendicular. So likewise is a part of the west wall, but that on the east is nearly level with the ground. All the arches of this church are circular, except two in the chancel and one in the north aisle, but these, as well as a pointed arch over the north aisle, seem to be of later date than the rest of the building. The columns of the nave are of four kinds, very massy, and variously ornamented. The bases and capitals are plain. Over each arch are large windows in pairs, and over them again are smaller arches. One of the ribs of the arch, which supported the tower, is still standing. It is richly ornamented with Saxon zigzag, as is also the western door and some other arches. The stones of which this church is constructed are of a deep red colour.

colour. On the sides most exposed to the weather they are eaten into the semblance of honeycomb. The remains of the priory and offices lie on the south side. The inside of their walls is built of whin-stone, obtained from a rock which forms a lofty natural pier on the south shore of the island. The pedestal of St. Cuthbert's cross, anciently held in great veneration, and now called the *polling stone*, is situated a short way to the east. When a bride cannot step the length of it, the superstitious reckon it ominous of future unhappiness in the marriage state. The parish church is a plain but spacious structure, having semicircular arches on the one side and pointed ones on the other. The windows are long and narrow. The chancel stands upon a lofty whin-stone rock on the south-east portion of the island. At the commencement of the civil wars it was garrisoned by the king's forces, but shortly after, fell into the hands of the parliament. The Pretender attempted to obtain possession of it in the year 1715. A detachment of invalids is now usually stationed here. *Hodgson's Beauties of Northumberland*, Svo. 1811.

LINDO, a town, or rather the remains of a town, in the island of Rhodes, anciently called *Lindus*, the native place of Cleobulus, one of the seven wise men of Greece, and of Chares, who made or at least began the famous colossus, consecrated to the sun, and the site of a magnificent temple dedicated to Minerva. This temple is said to have been built by Danaus, king of Egypt, on landing here in his flight from his own kingdom. A festival was celebrated here, not with blessings and prayers, but, as Lactantius says, with curses and imprecations; inasmuch that if a good word escaped from any person present, it was deemed a bad omen, and the ceremony was begun anew. The vestiges of this city, called *Lindo*, are seated in a hamlet nearly in the middle of the E. side of the island, and altogether peopled by Greeks; its harbour, though far from being spacious, is much frequented by the small craft of the country; which there take in the commodities of the island and bring thither merchandise from other parts. Accordingly almost all the inhabitants of Lindo are addicted to commerce, or to the carrying trade of the neighbouring coasts and islands; they navigate with small fast-sailing vessels constructed by themselves, and to which they give greater solidity than the ships which come off the stocks of Rhodes, on account of government. A few Lindians also employ themselves in rural labours, but as the part of the island which they inhabit is less capable of tillage than any other parts, on account of its stony soil, their culture principally consists of plantations of vines, fig-trees, and such others; 14 miles S.S.W. of Rhodes. N. lat. 36° 17'. E. long. 27° 38'. Sonnini.

LINDON, a small island on the W. side of the gulf of Bothnia. N. lat. 60° 55'. E. long. 16° 57'.

LINDOW, a town of Brandenburg, in the Middle Mark; 33 miles N.N.W. of Berlin. N. lat. 52° 57'. E. long. 13°.—Also, a town of Brandenburg, in the Middle Mark; 8 miles S.S.W. of Frankfort on the Oder.

LINDSÆA, in *Botany*, a genus of ferns, so named by the late Mr. Dryander, after Mr. John Lindsay, "an assiduous and skilful botanist of Jamaica," author of a paper, printed in the *Transactions of the Linnæan Soc.* v. 2. p. 93, on the germination and raising of ferns from the seed; as well as of another paper, in the same vol. p. 313, concerning the raising of several other cryptogamic plants in the same manner. Dryandr. *Tr. of Linn. Soc.* v. 3. p. 39. *Sm. Mem. de l'Acad. de Turin*, v. 5. p. 413. t. 9. f. 4. *Tracts on Nat. Hist.* 242. t. 1. f. 4. Swartz. *Fil.* 118. *Brown Prodr. Nov. Holl.* v. 1. 156. = Class and order,

Cryptogamia Filices. Nat. Ord. *Filices darsifera*, Linn. *Jussl.*

Gen. Ch. *Capsules* annulated, in continued, nearly marginal, lateral or terminal, lines. *Involucrum* arising from the surface of the leaf, membranous, continued, entire or slightly crenate, at length reflexed, permanent.

Est. Ch. *Fructification* in continued, nearly marginal, lines. *Involucrum* from the surface of the leaf, continued, separating at the side towards the margin.

Nine species are described in Mr. Dryander's original essay, to which five are added by Dr. Swartz, one by M. Labillardiere and one by Mr. Brown.

1. *L. sagittata*. Dryandr. n. 1. (*Adiantum sagittatum*, Aubl. *Guian.* 964. t. 366).—Frond simple, arrow or heart-shaped, with a taper point.—Native of woods and fissures of rocks in Guiana. The root is creeping, bearing five or six fronds in a cluster, near a span high; the stalks black and shining; leaf smooth, with dichotomous veins all springing from its base where the stalk is inserted; line of fructification about a straw's breadth from the edge.

2. *L. reniformis*. Dryandr. n. 2. *Tr. of Linn. Soc.* v. 3. t. 7. f. 1.—Frond simple, kidney-shaped, obtuse.—Native of Guiana and Surinam.—Much like the last, of which we are inclined to suspect it a variety.

3. *L. ensifolia*. Swartz n. 3.—Frond pinnate; leaflets alternate, sword-shaped.—From the island of Mauritius. We have what answers to this character, from Madagascar; but if right, it is very nearly allied to the following.

4. *L. lanceolata*. Brown. n. 2. *Labill. Nov. Holl.* v. 2. 98. t. 248. f. 1.—Frond pinnate; leaflets alternate, linear-lanceolate, sometimes pinnatifid; stalk square.—Found by Labillardiere at Van Diemen's land; by Mr. Brown in the tropical part of New Holland. Each leaflet is about one and a half inch or two inches long, nearly sessile. If the dichotomous form, and great distance of the lateral veins from each other, which are very remarkable characters in Labillardiere's plate, be correct, this species is essentially distinct from the last, whose veins compose an uniform sort of network, interbranching with each other over the whole disk of the leaf.

5. *L. grandifolia*. Frond pinnate; leaflets opposite, elliptic-lanceolate, pointed. Fructification half way between the rib and the margin.—Gathered in Malacca.—We know this merely from a pencil sketch taken by the younger Linnæus, marked with the native country of the plant, and a note saying it "probably constitutes a new genus, of which Aublet's tab. 365 and 366, and an *Adiantum* of Smeathman's, are other species." This was perhaps written at Sir Jos. Banks's; but if so, we cannot account for Mr. Dryander's having omitted this species, which appears to be one of the most remarkable of the whole number. The frond consists of two pair of opposite, slightly stalked, leaflets, three or four inches long, with a terminal one still longer. A line of fructification lies midway between the rib and the margin, on each side of the former; but none of the lines extend either to the base or the summit, by near an inch.

6. *L. linearis*. Swartz n. 4. 318. t. 3. f. 3.—Frond pinnate, linear; leaflets very numerous, fan-shaped, finely crenate and fructifying at their outer edge.—Native of various parts of New Holland. We have it from Port Jackson. About a foot high, with a dark polished stalk, tapering and zigzag at the base. The leaflets are imperfectly opposite, reflexed, small, broad and very short, so as to give a remarkable narrowness to the shape of the whole frond.

7. *L. falcata*. Dryander. n. 3. t. 7. f. 2.—Frond pinnate; leaflets somewhat crescent-shaped, entire, wavy.—Gathered by Aublet in Guiana.—About a foot high, with several pair

pair of rather close *leaflets*, each about an inch long, slightly falcate backward, wavy at their upper edge, along which runs the line of fructification. The terminal *leaflet* is irregularly shaped.

8. *L. heterophylla*. Dryandr. n. 4. t. 8. f. 1. — Frond pinnate; leaflets entire or serrated; the lower ones somewhat rhomboid-lanceolate, pointed; the upper rhomboid and very obtuse; the uppermost confluent. — Gathered by Mr. Robertson at Malacca. A span high, with very various, slightly distant *leaflets*, the longest of which measure scarcely an inch.

9. *L. cultrata*. Swartz. n. 7. (*Adiantum cultratum*; Willd. Phytogr. fasc. t. 14. t. 10. f. 2.) Frond pinnate; leaflets oblong, obtuse, wavy at their upper margin; the terminal one elongated jagged. Native of the coast of Malabar. — Frond about five inches high, with a green *stalk*, 10 or 12 pair of alternate, stalked, horizontal *leaflets*, and a singularly jagged, elongated, upright terminal one.

10. *L. flabellulata*. Dryandr. n. 5. t. 8. f. 2. — Frond pinnate; leaflets fan-shaped, finely toothed; the lower ones of the old plants compound. Native of China, Macao, and Sumatra. — The *leaflets* are almost semicircular at their fructifying edge, which stands outwards, not uppermost.

11. *L. trapeziformis*. Dryandr. n. 6. t. 9. — Frond doubly pinnate; leaflets quadrangular, abrupt; the lowermost fan-shaped. — Gathered in Grenada by Smeathman; see our n. 5. — A large and handsome fern, each branch of whose *frond* consists of above a dozen pair of oblong quadrangular leaflets, fructifying at their upper and outer margins.

12. *L. guianensis*. Dryandr. n. 7. (*Adiantum guianense*; Aubl. Guian. 962. t. 365.) — Frond doubly pinnate; its branches spreading, tapering; leaflets crowded; the lower lunate; middle ones square; upper fan-shaped. — Gathered by Aublet at the bottoms of little hills in the forests of Guiana. This is a very handsome fern, two or three feet high, with a longish *stalk*, and about six pair of nearly opposite, tapering, widely spreading *branches*, each composed of innumerable, crowded, light green *leaflets*, more or less rounded in their upper or fore-part, which is bordered with a broad brown line of fructification.

13. *L. stricta*. Dryandr. n. 8. Swartz Ind. Occ. 1722. (*Adiantum strictum*; Swartz Prodr. 135.) — Frond doubly pinnate; branches erect, contracted; leaflets trapeziform. — Native of Jamaica, Porto Rico, and Panama. — No figure of this species has yet appeared.

14. *L. media*. Brown n. 3. — Frond doubly pinnate; deltoid; leaflets obovato-rhomboid, coriaceous; the lower ones lobed; the rest entire; with a solitary uninterrupted line of fructification at the fore edge; the barren ones serrated at the top; stalk square. — Gathered by Mr. Brown in the tropical part of New Holland.

15. *L. trichomanoides*. Dryandr. n. 9. t. 11. — Frond doubly pinnate; leaflets membranous, linear-clubshaped, abrupt. — Gathered at Dusky bay, New Zealand, by Mr. A. Menzies. A delicate species, a span high, with slender creeping downy roots, and smooth brown stalks. The *leaflets* vary in size and breadth, but are nearly wedge-shaped, decurrent and confluent, of a light green colour and somewhat membranous texture, so as much to resemble a *Trichomanes* or *Hymenophyllum*; their summit abrupt, crenate or jagged. Line of fructification sometimes very short; the *involucrum* broadish, scarcely ever reflexed, but finally deciduous, along with the capsules.

16. *L. tenera*. Dryandr. n. 10. t. 10. — Frond triply pinnate, triangular; leaflets obovate, somewhat rhomboid, ent. — Native of the East Indies; sent to sir Joseph Banks by the Moravian missionaries from the island of Nicobar. It appears to us as truly pinnate as any of the others, rather

than pinnatifid, though the ultimate divisions, or *leaflets*, are decurrent; these are broader and more rounded than in the last, as well as lobed or cut.

17. *L. microphylla*. Swartz n. 14. 319. — Frond lanceolate, triply pinnate; leaflets wedge-shaped, dilated and crenate at the top. Gathered near Port Jackson, New South Wales, by Dr. White. This elegant species is a foot and a half, or more, in height; the whole *frond* of a narrow lanceolate figure, with slender, lax, pinnate branches, and small, light green dotted *leaflets*, which are wedge-shaped, tapering at the base, always crenate at the summit, as is also the *involucrum*. Every *leaflet* is suddenly dilated opposite to each end of the fructifying line.

The three last species are naturally allied to the genus *Davallia* (see that article), with which they agree as to habit, and occasionally even in the short round figure of their fructification and involucre, which in general however are continued in a submarginal line.

LINDSAY, JOHN, in *Biography*, a learned nonjuring divine, who was educated at St. Mary-Hall, Oxford. He had a congregation in London, among whom he regularly officiated, and was employed by Mr. Bowyer as a corrector of the press. He translated Mafon's "Vindication of the Church of England;" and wrote "A Short History of the Royal Succession;" and "Remarks on Whiston's Scripture Politics." He died in 1768, aged 82.

LINDSAY, Sir DAVID, a Scotch poet, was a native of the county of Fife, and educated at the university of St. Andrews. He was at the battle of Pavia, and on his return to Scotland James V. appointed him master of the herald's office. He wrote several poems, some of which have been printed, particularly his *Satires on the Clergy*. He died in 1557, aged 61. There was another of this family named David likewise, who was born about the year 1527; he was a zealous promoter of the reformation, and died in 1592. He wrote the History of Scotland from 1437 to 1542.

LINDSEY, THEOPHILUS, was born at Middleswich, in Cheshire, June 20th, 1723, old style. His father, Mr. Robert Lindsey, was an opulent proprietor of the salt-works in that neighbourhood; his mother's name was Spencer, a younger branch of the Spencer family, in the county of Buckingham. Theophilus was the second of three children, and so named after his godfather, Theophilus, earl of Huntingdon. He received the rudiments of grammar learning at Middleswich, and from his early attachment to books, and the habitual seriousness of his mind, he was intended by his mother for the church. He lost some time by a change of schools, till he was put under the care of Mr. Barnard of the free-school of Leeds, under whom he made a rapid progress in classical learning. At the age of eighteen he was admitted of St. John's college, Cambridge, where, by exemplary diligence and moral conduct, he obtained the entire approbation of his tutors. As soon as he had finished his studies at college, taken his first degree, and had been admitted to deacon's orders, he was nominated by sir George Wheeler to a chapel in Spital square, London. Soon after this, he was, by the recommendation of the earl of Huntingdon, appointed domestic chaplain to Algernon, duke of Somerset. The duke, from a great regard for his merit, determined to procure him a high rank in the church, but an early death deprived Mr. Lindsey of his illustrious patron. In 1754, he accompanied the present duke of Northumberland to the continent, and on his return he supplied, for some time, the temporary vacancy of a good living in the north of England, called Kirkby-Wilf: here he became acquainted with Mr. archdeacon Blackburne, and in 1760 married

ried his daughter-in-law. From Kirkby Mr. Lindsey went to Piddletown, in Dorsetshire, having been presented to the living of that place by the earl of Huntingdon: this, through the interest of the same patron, he exchanged, in 1764, for the vicarage of Catterick, in Yorkshire. Here he resided nearly ten years, an exemplary pattern of a primitive and conscientious pastor, highly respected and beloved by the people committed to his charge. Besides his various and important duties as a parish clergyman, Mr. Lindsey was ever alive, and heartily active, in every cause in which the principles of truth and right reason were concerned. We accordingly find him, in 1771, zealously co-operating with Mr. archdeacon Blackburne, Dr. John Jebb, Mr. Wyvil, and others, in endeavouring to obtain relief in matters of subscription to the thirty-nine articles: the object of these gentlemen was simply this, that the clergy of the established church might be permitted to hold their preferments upon condition of merely subscribing their belief of the holy scriptures, instead of the thirty-nine articles. The question was brought before the house of commons in 1772, but after a very animated discussion, it was lost by a great majority. Considering the issue of this debate as an absolute disappointment and refusal of all their just and righteous demands, he began to consider what course he should take to satisfy his conscience, and in a short time explicitly avowed his intentions of resigning his living. He had, probably, for some years, had doubts with respect to the doctrine of the Trinity, and other leading topics of the established faith, and early in the year 1773 an anonymous writer, under the signature of Lælius, started the subject of the impropriety of persons remaining in the church who could not conscientiously conform to her principles: to this Mr. Lindsey, in a letter to a friend, most feelingly alludes; "The subject of Lælius's last letter may give one many a pang. I cannot say that I have been for many years a day free from uneasiness about it." In the following November he wrote to the prelate of his diocese, informing him of his intention to quit the church, and signifying, that in a few days he should transmit to him his deed of resignation. The bishop endeavoured to persuade him to remain at his post, but he had made up his mind that duty required the sacrifice, and he was resolved to bear the consequences. When the act was done, he said he felt himself delivered from a load which had long lain heavy upon him, and at times nearly overwhelmed him. Previously to his quitting Catterick, Mr. Lindsey delivered a farewell address to his parishioners, in which he stated his motives for quitting them, in a simple and very affecting manner, pointing out the reasons why he could no longer conduct, nor join in their worship, without the guilt of continuing insincerity before God, and endangering the loss of his favour for ever. He left Catterick about the middle of December, and after visiting some friends in different parts of the country, he arrived in London in January 1774, where he met with friends, who zealously patronized the idea which he entertained of opening a place of worship, devoted entirely to Unitarian principles. A large room was at first fitted up for the purpose in Essex-street in the Strand, which, after overcomng some legal obstacles, the owners by the magistrates in the way of registering it, was opened April 17, 1774. The service of the place was conducted according to the plan of a liturgy which had been altered from that used in the established church by the late Dr. Samuel Clarke, rector of St. James's church, Piccadilly, London. Mr. Lindsey published the sermon which he preached on the opening of his chapel, to which was added an account of the liturgy made use of. About the same time he published his "Apology," of which several editions were called for in the course of a few years. This was fol-

lowed by a still larger volume, entitled "A Sequel to the Apology," which was intended as a reply to his various opponents, and likewise to vindicate and establish the leading doctrines which he professed, and on account of which he had given up his preferment in the church. This work was published in 1776, and in 1778 he was enabled, with the assistance of his friends, to build the chapel of Unitarianism, and to purchase the ground on which it stands. In the summer of 1793, Mr. Lindsey, with the aid of his friend the Rev. Dr. Disney, conducted the services of the place, upon strict Unitarian principles, to a respectable and numerous congregation. He then resigned the whole into the hands of his very able coadjutor, notwithstanding the earnest wishes of his hearers that he should still continue a part of the services. Though he had quitted the duties of the pulpit, he continued to labour in the cause, by his publications, till he had attained his eightieth year. In 1802 he published his last work, entitled "Consistency of the Divine Government, shewing that every Thing is from God, and for good to all." The object of this piece, which has been reprinted for general circulation by a society for promoting Christian knowledge, &c. is to vindicate the Christian religion, those gloomy notions which are too often attached to its providence, and to shew that the government of the world is the wisest that could have been adopted, and that afflictions and apparent evils are permitted for the general good. From this principle Mr. Lindsey derived consolation through life, and upon it he acted in every difficult and trying season. On his death-bed he spoke of his sufferings with perfect patience and meekness, and when reminded, by a friend, that he doubtless was enabled to bear them with so much fortitude in the recollection of his favourite maxim, that "Whatever is, is right;" no, said the dying Christian, with animation that lighted up his countenance, "Whatever is, is best." This was the last sentence which he was able distinctly to articulate: he died November 3, 1808. Besides the works already referred to, he published two dissertations: 1. On the Preface to St. John's Gospel; 2. On praying to Christ: "An Historical View of the State of the Unitarian Doctrine and Worship from the Reformation to our own Times;" and several other pieces. Among controversial writers Mr. Lindsey takes a very respectable place, as his "Vindication of Priesthood," and his "Examination of Mr. Robinson's Plea for the Divinity of Christ," will shew. In every character of life which this excellent man sustained, he acted his part with honour and integrity, and for his exertions in the cause of truth and rational Christianity, whatever may be thought of his particular opinions, many will rise up and call him blessed. Ours, equally devout, equally humble, equally pious men, will be forgotten when the name of Theophilus Lindsey shall be held in veneration, because to humility, purity, and perseverance, he added a courageous avowal of what he believed to be the truth: he bore public testimony, in opposition to the penal laws, in matters of faith, that still exist on our Statute-book, to the unity of God at the hazard of all. Two volumes of his sermons have been published since his death. Monday Mag. Dec. 1808.

LINDUM, in *Ancient Geography*, a town of Britain, in the country of the Coræti, which by the 5th Dec. of Antonine is situated between Caudeboræ or Ancaster, and Begeboræ or Louthborough. This is universally agreed to be Lincoln, which was a Roman colony, and a place of great importance in ancient times. Baxter, without sufficient authority, contends that Lindum was the Lindum in which so many of the Romans were slain by the Britons in their great revolt under Boadicea. See LINCOLN.

LINDUM was also the name of a place in the country of the

the Dumnii; which, in both the sound and signification of the name, bears so great a resemblance to Linlithgow, that it is most probably the same place, though its situation does not exactly agree with that assigned by Ptolemy, who is far from being correct in this particular,

LINDY, in *Geography*, a town of Africa, in Querimba, S. lat. $9^{\circ} 58'$. E. long. $41^{\circ} 4'$.

LINE, in *Geometry*, a quantity extended in length only, without either breadth or thickness.

A line is supposed to be formed by the flux or motion of a point; and is to be conceived as the termination or limit of a surface, and not as a part of that surface, however small.

There are two kinds of lines; viz. *right* lines, and *curve* lines.

If the point A moves towards B (*Pl. X. Geometry, fig. 1.*) by its motion it describes a line: and this, if the point go the nearest way towards B, will be a right or straight line, whose definition therefore is the nearest or shortest distance between any two points. or a line, all whose points tend the same way. If the point go any way about, as in the lines A C B, or A c B, it will trace out either a crooked line, as the upper A c B; or else two or more straight ones, as in the lower A C, C B.

Right lines are all of the same species: but *curves* are of an infinite number of different species; we may conceive as many as there are different compound motions, or as many as there may be different ratios between their ordinates and abscissas.

Curve lines are usually divided into *geometrical* and *mechanical*. The former are those which may be found exactly and securely in all their points. (See *GEOMETRICAL line.*) The latter are those, some or all of whose points are not to be found precisely, but only tentatively, or nearly.

Accordingly, Descartes and his followers define *geometrical* lines, those which may be expressed by an algebraic equation of a determinate degree; which equation is also called *locus*.

The same persons define *mechanical* lines those which cannot be expressed by an equation of a determinate degree. Others, considering that those called by Descartes *mechanical* lines, notwithstanding their not being of a determinate degree, are not less precise and exact, and consequently not less geometrical than the others; it being this precision which constitutes the geometricity of the line: for this reason, choose rather to call those lines which are reducible to a determinate degree, *algebraical* lines; and those which are not, *transcendental* lines.

Lines are also divided into those of the *first order*, *second order*, *third order*, &c. See *CURVE*.

Sir Isaac Newton enumerated seventy-two lines of the third order, and Mr. Stirling found four more; since that Mr. Stone has found two others, which had escaped Sir Isaac and Mr. Stirling. The two species added are to be reckoned among the hyperbolico-parabolical curves. Enumer. Lin. Tert. Ordin. Linea. Tert. Ordin. Newtonianæ, Oxon. 1717. Svo. Phil. Transf. N^o 476. § 6. See *CURVE*.

Lines, considered as to their positions, are either *parallel*, *perpendicular*, or *oblique*; the construction and properties of each whereof, see under *PARALLEL*, *PERPENDICULAR*, &c.

Euclid's second book treats mostly of lines, and of the effects of their being divided, and again multiplied into one another.

LINES, *Algebraic*, are divided into different orders, according to the degree of their equations. These degrees are

estimated, as in determined equations, by the degree of the highest term of the equation.

Thus $a + by + cx = 0$, is a general equation, expressing the nature of lines of the first order, or of straight lines.

The equation $a + by + cx + dyy + exy + fxx = 0$, represents the lines of the second order; that is, the conic sections, and the circle, which is one of them.

And the equation $a + by + cx + dyy + exy + fxx + gyy + hxy + ixx + lxx = 0$, expresses in general the lines of the third order. And the lines of the fourth and higher orders may be expressed in the like manner. See *Cramer* *Introd. à l'Analyse des Lignes Courbes*, p. 52, seq. Mr. Cramer uses the terms *lines* of the second, third, fourth, &c. order, and *curve* of the second, third, fourth, &c. order, indifferently. Sir Isaac Newton has made a distinction, according to him. See *CURVE*.

LINES, *circular*, *converging*, *diverging*, *generating*, *heli-spherical*, *hyperbolic*, *logislic*, *magnetical*, *normal*, *proportional*, *quadrature*, *reciprocal*, *robervalian*, and *vertical*. See the respective adjectives.

LINE of the *Apsides*, in *Astronomy*, is the line which joins the apses; or it is the greater axis of the orbit of a planet.

LINE, *Fiducial*, the line or ruler which passes through the middle of an astrolabe, or the like instrument; and on which the sights are fitted; otherwise called *albidude*, *index*, *dioptra*, and *medicinium*.

LINE, *Horizontal*, a line parallel to the horizon.

LINES, *Isochronal* and *Meridian*. See the adjectives.

LINE of the *Nodes*, in *Astronomy*, is the line which joins the nodes of the orbit of a planet, or the common section of the plane of the orbit with the plane of the ecliptic.

LINE, *Horizontal*, in *Dialling*, is the common section of the horizon, and the dial-plate.

LINES, *Hourly*, or *Hour-lines*, are the common intersections of the hour-circles of the sphere, with the plane of the dial. See *HORARY*, and *Hour-circles*.

LINE, *Subsylar*. See *SUBSYLAR*.

LINE, *Equinoctial*, is the common intersection of the equinoctial, and the plane of the dial.

LINE, *Contingent*. See *CONTINGENT*.

LINES, *Dialling* and *Meridian*. See the respective adjectives.

LINE, in *Fencing*, is that part of the body directly opposite to the enemy, wherein the shoulders, the right arm, and the sword, ought always to be found; and wherein are also to be placed the two feet, at the distance of eighteen inches from each other.

In this sense, a man is said to be in his line, to go out of his line, &c.

LINE, in *Fortification*, is sometimes taken for a ditch, bordered with its parapet; and sometimes for a row of gabions, or sacks of earth, extended lengthwise on the ground, to serve as a shelter against the enemy's fire.

When the trenches were carried on within thirty paces of the glacis, they drew two lines, one on the right, and the other on the left, for a place of arms.

For the difference between trenches or approaches, and lines, see *INTRENCHMENT*.

Lines are generally made to shut up an avenue or entrance to some place; the sides of that entrance being covered by rivers, woods, mountains, morasses, or other obstructions, not easy to be passed over by an army. When they are constructed in an open country, they are carried round the place to be defended, and resemble the lines surrounding a camp, called lines of circumvallation. Lines are likewise thrown

thrown up to stop the progress of an army; but the term is most commonly applied to the line which covers a pass that can only be attacked in front. For constructing such a line in the place most convenient for the purpose, let a rope be run quite across the way along the intended place of the line, pegging it to the ground at the distance of every four or five yards; and at the distance of about ten or twelve feet before the line, towards the enemy, let such another line or row of stakes be carried in a position parallel to the first rope. When the labourers are properly ranged within these limits, let them dig up the earth in this breadth, and throw it on the other side of the first rope, until a bank of about five or six feet thick, and six or seven feet high, be raised, sloping the sides according to the declivity necessary for the earth's rolling naturally down the bank; and let the digging be continued till the ditch is about five or six feet deep, the breadth of the bottom being about one-third of the breadth staked out at top: the bank may be rendered more firm by being trod or rammed down. Let the inner side of the bank be pared with the spade into such a slope, as a man standing upright may easily touch with his arm extended straight before him; and at the foot of this bank, let a foot-bank or step be raised, of such a height, as a man standing on it may easily fire his musket over the bank, or let it be about four feet and a half lower than the top of the bank or breast-work. A gentle slope may also be made to the foot-bank, that the troops may more easily ascend it; and let the crown or top of the breast-work be sloped so, that a musket laid flat on it may strike the ground with its shot, about five or six feet beyond the ditch. The bank or breast-work will, in this case, secure the troops behind the lines from the enemy's fire; and when they stand on the foot-bank, they are more than two-thirds covered, and, consequently, the troops within may make three of their shots tell for one of the enemy; and by going off the foot-bank, they may be quite covered, while they load again; so that with this advantage, they are in no great danger of being forced from the lines, unless the enemy are greatly superior in number and cannon.

The following Table shews the dimensions of lines commonly constructed, and the rate of expence attending the construction of them.

Breast-Work.			Ditch.			Expence.	
Thickness at top.	Height within.	Height without.	Upper breadth.	Lower breadth.	Depth.	Solid Content.	Days' work.
Feet.	Feet.	Feet.	Feet.	Feet.	Feet.	Feet.	
4	$7\frac{1}{2}$	6	8	$2\frac{3}{4}$	5	$4\frac{3}{4}$	1
5	$7\frac{1}{2}$	6	10	$3\frac{1}{4}$	$5\frac{1}{2}$	$6\frac{1}{4}$	$1\frac{1}{2}$
6	$7\frac{1}{2}$	6	12	4	6	8	2
7	$7\frac{1}{2}$	6	14	$4\frac{1}{2}$	$6\frac{1}{2}$	10	$2\frac{1}{2}$
8	$7\frac{1}{2}$	6	16	$5\frac{1}{2}$	7	12	3
9	$7\frac{1}{2}$	6	18	6	$7\frac{1}{2}$	15	$3\frac{1}{2}$

The day's work here is for one yard in length; and in the first, a hundred men will complete a hundred yards in length of this kind of lines in one day; two hundred men in half a day, &c. The lines above described are called temporary lines, and chiefly serve a present emergency. When lines are thrown up at leisure, and designed for longer duration, then the ditch is usually eighteen feet broad at

top, seven or eight feet deep, and the sides of the ditch are sloped, so as to leave only six feet breadth at bottom; the breast-work, or parapet, is about seven feet thick on the top or crown, and seven or eight feet high. The heights, depths, and breadths, of the several parts of a line well designed and finished, are exhibited in *Plate VI. Fortification, fig. 3*, in which *IL* represents the ground line, or surface of the place; *AB* the breadth of the ditch at the top; *CD* its breadth at the bottom; *FAC* the slope or scarp of the parapet and ditch; *DBK* the counterescarp; *FF* the top or crown of the parapet or breast-work; *EG* the inner slope of the parapet; *HG* the top of the foot-bank; *HI* the slope of the foot-bank; and *BKL* a small sloping bank, called the glacis. This section or profile may be drawn, by laying off in the ground-line, from any scale of equal parts, the distances $a = 6$ feet, $ab = 4$, $bc = 1\frac{1}{2}$, $cd = 7$, $dA = 4\frac{1}{2}$, $Af = 6$, $fg = 6$, $gB = 6$, and $BL = 5$ feet. Through a, b, c, d, f, g, B , draw lines perpendicular to *IL*. Make $aH = 2\frac{1}{2}$ feet = bG , $cE = 7$ feet, $dF = 6$, $fC = 8$ feet = gD . Draw *IH, HG, GE, EF, FAC, CD*, and *DB*, which continue, till it meets the line *FL*, and the profile is constructed.

When lines are made to cover a camp, or a large tract of land, where a considerable body of troops is posted, the work is not made in one straight, or uniformly bending line; but at certain distances, the lines project in salient angles, called redents, redans, or flankers, towards the enemy. The distance between these angles is usually between the limits of two hundred and two hundred and sixty yards; the ordinary flight of a musket-ball, point-blank, being generally within those limits; although muskets, a little elevated, will do effectual service at the distance of three hundred and sixty yards. In *Plate VI. Fortification, fig. 4*, are shewn the forms of the usual lines, where the figures *CAB, cab*, are the redents or flankers; *AC, AB, ac*, ab , the faces; *CB, cb*, the gorges; *AD, ad*, the capitals; *Bb* the curtain; and the angles *CAB, cab*, the salient or flanked angles. The distance of the salient angles is about two hundred and forty yards at a mean; the length of the capital is usually between forty and fifty yards, and the length of the gorges is also about sixty or seventy yards.

To make a plan of lines with redents; draw the line *EEEE*, &c. (*Plate VI. Fortification, fig. 5*.) in such a manner, that, wherever there is a bend or angle, it may be either at once, twice, or thrice, &c. the length of about two hundred and forty yards from one another; so that there may be a redent where there is an angle. In this line, lay off the distance of two hundred and forty yards from *E* to *E*, *E* to *E*, &c. reckoning from the bends towards each end, whether it happens that the line will or will not be exactly measured by a repetition of the two hundred and forty yards. At each point, *E*, draw the capital *EF* in a perpendicular position to the direction of the line in that point, and make the capitals about forty or fifty yards long. On each side of *E*, take the half gorges *EG, EG*, each of about thirty or thirty-five yards, and draw the faces *FG, FG*; and thus the out-line, or mauler-line, of the curtains and redents is formed. Parallel to each curtain and face draw lines, within, at the distances from the mauler-line of seven feet, eight feet, twelve feet, and eighteen feet; then the breadth of seven feet represents the plan of the parapet, that of one foot its inner slope, that of four feet the top of the foot-bank, and that of six feet the foot-bank slope. On the outside of the mauler-line, draw lines at the distance of $10\frac{1}{2}$, $16\frac{1}{2}$ and $22\frac{1}{2}$ feet parallel to each curtain and face; and these will represent the plans of the scarp, ditch,

ditch, and counter-scarp; observing that the salient angles of the counter-scarp are rounded before the angles of the redans. A plan of this kind formed from a small teale, as of twenty yards to an inch, is usually represented by four parallel lines; one without the outer-line, representing the counter-scarp or out-line of the ditch, and two within, representing the breadth of the parapet of the foot-bank. In some cases, a short line is hastily formed by a number of *chevaux de frise* chained together; and in countries abounding with wood, a line may be formed by laying, in a position pointing to the enemy, the stems of trees and their larger branches, piled on one another to a sufficient height, and the interstices filled with earth; such a work is called an *abatis*. See Robertson's *Marine Fort.* p. 2. See.

LINE, *Fundamental*, is the first line drawn for the plan of a place, and which shows its area.

LINE, *Capital*, in *Fortification*. See **CAPITAL**.

LINE, *Central*, is that drawn from the angle of the centre, to that of the bastion.

LINE of *Defence*. See **DEFENCE**.

LINE of *Defence* *sechant*. See **DEFENCE**.

LINE of *Defence* *razant*. See **DEFENCE**.

LINE of *Approach*, or *Attack*, signifies the work which the besiegers carry on under covert, to gain the moat, and the body of the place. See **APPROACH**.

LINE of *Counter-approach*. See **COUNTER-approach**. See **PLATE VI. Fortification, fig. 6.**

LINE of *Circumvallation*, is a line or trench cut by the besiegers, within cannon-shot of the place, which ranges round their camp, and secures their quarters against any relief to be brought to the besieged. See **CIRCUMVALLATION**.

LINE of *Contravallation*, is a ditch bordered with a parapet, which serves to cover the besiegers on the side of the place, and to stop the sallies of the garrison. See **CONTRAVALLATION**.

LINE of *Communication*, are those which run from one work to another. See **PLATE VI. Fortification, fig. 7.** See also **COMMUNICATION**. But

The **LINE** of *Communication*, more especially so called, is a continued trench, with which a circumvallation, or contravallation is surrounded; and which maintains a communication with all its forts, redoubts, and tenailles.

LINE of *the Base*, is a right line, which joins the points of the two nearest bastions.

To LINE a *Work*, signifies to face it, chiefly with brick or stone; i. e. to strengthen a rampart with a firm wall, or to encircums a parapet or moat with good turf, &c.

LINE, *Individed*, in *Fortification*. See **REDANS**.

LINEs, among *Trappers*, are used to express the strings by which they catch birds. The large and small land birds are taken by them with equal ease, and sometimes the water-fowl.

These lines are made of long and small cords, knotted in different places, and containing in length as many fathom as the places where they are to be laid require. Plovers, and the larger wild-fowl, are very conveniently taken by them. When these strings are to be used, they must be lined with the strongest bird-line that can be got, and then coming to their haunts before the evening flights, that is, before sun-set; or, for the morning flights, at least two hours before day, the sportsman is to carry a parcel of small sticks, each about two feet long, and sharpened at both ends, but having a little flat at one end like a fork. The plain end of each stick is to be stuck into the ground, in such a manner, that the stick standing upright, its upper, or forked end, may be about a foot and a half from the surface. The lined strings are then to be carried along all these sticks, in different rows,

some higher than others. Every row of the sticks is thus to be filled, and the whole haunt covered with the lines. The plover, and other birds that fly low, when they come to their haunts, fly directly in amongst the strings, and are taken in great numbers; the whole flight coming in at once, and covering all the place, so that those which are not yet alighted, have no opportunity of seeing the distress of their companions. There is no need for the sportsman to be constantly upon the watch for the taking of the birds; for when once they are taken they cannot loosen themselves, so that he may come and take them up at his own time. The water-fowl may be easily taken, in the same manner, by observing their haunts, and stretching these lines, in several rows, across the brook, or river, some higher, and some lower, the lowest lying almost at the edge of the water. These must never be used on moonlight nights on the occasion; for the shadow of the strings, in the water will then fright them away.

LINE, in *Genealogy*, is a series of succession or relations in various degrees, all descending from the same common father.

LINE, *Direct*, is that which goes from father to son; which is the order of ascendants and descendants. See **DIRECT**.

LINE, *Collateral*, is the order of those who descend from some common father, related to the former, but out of the line of ascendants and descendants. In this are placed uncles, aunts, cousins, nephews, &c. See **COLLATERAL**. See also **CONSANGUINITY** and **DESCENT**.

LINE, in *Geography* and *Navigation*, is used by way of eminence for the equator or equinoctial line.

The line in the heavens is a circle described by the sun in his course on the 20th day of March, and the 23d of September. The line on the earth is an imaginary circle answering to that in the heavens. It divides the earth from east to west, into two equal parts, and is at an equal distance from the two poles; so that those who live under the line have the poles always in their horizon.

The latitudes commence from the line.

The seamen have sometimes practised the ceremony of christening their fresh men, and passengers, the first time they cross the line. See **BAPTISM**.

LINEs, in *Heraldry*, the figures used in armories to divide the shield into different parts, and to compose different figures.

They are of different forms, and were it not for this, many arms would be one and the same, for a chief wavy differs from a plain chief, by the lines which compose them, and the heralds shew particular reasons for all these different forms of lines.

These lines, according to their forms and names, give denomination to the pieces or figures which they form, except the straight or plain lines, which are carried evenly through the escutcheon, and are four, viz. the perpendicular line, the horizontal, the diagonal line dexter, and the diagonal line sinister.

The crooked lines, which are carried unevenly through the escutcheon, rising and falling, are these: first the engrailed or engrailed, and inverted or invected; these, when represented together, are somewhat known the one from the other, being opposite to one another, both being made, as it were, of semicircles: the engrailed with the points upward, the invected with the points downward. But this is not a sufficient distinction: for suppose the space between them which they form be a fess, then the whole is only engrailed, not invected; for the fess engrailed must have the points on both sides turned towards the field, and the convex

or gibbose parts toward the fess itself, and so of a bend, chevron, and other proper figures of heraldry; and if these be inverted, then the convex parts of the lines are towards the field; but these lines are better distinguished when placed by way of bordure, with the letters within a bordure engrailed or inverted.

These two lines are more hard to be distinguished, when the field is divided into two equal parts, of different colours, as parted per pale, parted per fess, &c. Here we know not whether the line be engrailed or inverted, except we follow this rule, that the form of the line must be applied to the colour first named. The French terms for these two lines are, for the engrailed, *engraillé*, and for the inverted, *canalé*; and the Latin writers express engrailed by *ingreditatus*, *imbriatus*, and *striatus*, and the inverted by the words *inversus* and *conculcatus*.

The wavy, or waved line, is such an one as is formed in representation of the waves of the sea, as parted per fess wavy in arms and other waved lines, as the wavy bars all express that the person got his honours by sea service.

Nebulee is another name of a line in heraldry: it expresses a clouded line; the French call it *nuage*, and the Latins *nebulosa linea*. This also has been given to persons who have been eminently skilled in navigation.

Crenelle, or embattled lines, represent the battlements of a house, and are said to represent in heraldry the skill in architecture, for which the first of the family was famous; they were also given sometimes for eminent services, in assaulting or defending castles in time of war, and sometimes only as emblems of a house to express a person who bore them being of a noble house or family; for of old, none were suffered to embattle their houses but persons of great distinction.

The Latin writers in heraldry use for the words *crenelle*, the terms *pinatus* and *pinnis asperatus*, according to Uredus in his blazons, and Sylvester Petra Sancta in his *murales pinnales*.

There is another line of this kind in heraldry, which Leigh calls the battle-embattled line: this has one degree of embattling above another. When the upper points in this kind of line are represented sharp, it is called *campagne*, as if the lines ending in points represented bastions, or the outer works of cities and camps; and when the upper points are rounded, it is called *crenelle embattled arrondi*.

The indented line is notched for at the edges, that it represents the teeth of a saw, and has its name from the Latin *dens*, a tooth, or from the law term *indenture*, a sort of deed, the top of which is always notched like the teeth of a saw.

The dancette is another line, very much resembling the indented line, but that it is always much smaller; it is therefore said by the heralds to be the same in quality, but not in quantity. The dancette differs also from the indented line, in that it always consists but of a few teeth, though never less than three, according to Mr. Holmes, in his Office of Armory; whereas the indented line has always a great many teeth. The French express our indented line by the term *danche* or *dentille*; and the dancette, when it has but very few teeth, and those very long, by the term *cinque*, which Menestrier takes to be the letter M, with its legs extended from side to side of the shield, because many who carry a partition, or fess, after that form, have the family name beginning with that letter. The Latin writers express the term indented by *dentatus*, *indentatus*, and *denticulatus*; and when the teeth are very long, as in the dancette, they call them *dentes decurvi*. See also NEBULE and RAGUED.

There are yet two other lines mentioned by the heraldry

writers: the first is the *pate* or *dovetail* line, so called from its resemblance to a sort of joint used by our carpenters, in which one part goes alternately all the way down between two others: this is called by Morgan the inclave, or labelled line, because the points, as they proceed from the ordinary, such as the chief or fess, represent not amidst the points, or rather the ends of the labels. The other line is called *urde* or *champagne* by Fresne; and by Upton, *vair*, because its points are formed like pieces of the fur, called by heralds *vair*.

The two last of these are of very little use, the others are the common lines of arms, and are called the attributes or accidents of armorial figures which they form; and if any other lines are found in the figures or engravings of arms, which are not reducible to the one or the other of these, they are called *irregular*, and by the French heralds *classe*. The knowledge and use of these forms of lines are necessary in the science of heraldry to distinguish and difference many armorial bearings.

LINE, *Latellid*. See LABELLED.

LINE, *Lateral*, *linea lateralis*, in *Ichthyology*, a name given by naturalists to a line or streak, with which many kinds of fish are marked, passing along their sides. Few fish are without this line; but it is variously formed in the several kinds, and makes a very considerable article in their description, if not in the distinction of the species. In some species it is made of a series of little points, or holes, as appears to the eye; of this nature is the line in eels, &c. In some others it is formed of a sort of duct, running along the centre of a great number of scales. This is its structure in the generality of fishes.

This line, in various kinds of fish, varies also in regard to number, situation, figure, and other properties. In regard to number, there is no line observed in the *syngnathus* and *petromyza*, in almost all other fish, there is one on each side; and, finally, in some there are as it were two lines on each side: an instance of this we have in the *ammodontæ*. In regard to the situation, the differences are these: 1. In some it is near the back, as in the *clupea*, *salmons*, *perch*, and the like. 2. In others it is placed nearer the belly, and runs parallel with it, as in the *cyprinæ*. 3. In some it is placed in the centre of each side between the back and the belly, as in the *carassius*. 4. In some it is placed against the interstices of the muscles, or *spina dorsalis*, as in the *muræna*. And, 5. In some it is placed above the interstices, as in the *ammodontæ*, &c. It has been supposed by many, that this *linea lateralis* was always parallel to the interstices of muscles; but this is evinced to be an erroneous opinion, by the observation of the *perch* and *mackerel*. In regard to the differences of figure, this line is in some straight, as in the *coregonæ*, *salmons*, &c. 2. In others it is crooked, as in the *cyprinæ*, the *perch*, &c. and in the generality of fish is smooth to the touch, but in some it is rough and aculeated, as in the *trachurus* and *pleuromæni*. See *dentatus* of FISHES.

LINE of the Banquet, in the *Mange*. See BANQUET.

LINE of a Vell. See SQUARE and VELL.

LINE of Division, in *Mechanick* and *Gunners*. See DIRECTION.

LINE of Gravitation of a Large Body, is a line drawn through its centre of gravity, and according to which it tends downward.

LINE of the point of Descent of a Large Body. See DESCENT and CENTRE.

LINE of a Piece of Cannon. See PROPORTIONS.

LINES, in *Opticks*. Time, being by, or by horizontal and parallel lines, compose the object, which is seen and has

tween which all music, since the invention of counterpoint, has been written.

The staff in canto fermo, or plain song, consisted only of a single line, drawn through or between the points or dots of different elevation, to aid the priests in chanting: then two, three, and, finally, four lines composed the staff for Gregorian notes in the missals and mass books, in Roman Catholic churches; and these have never been increased. Secular music for the virginal, spinnet, harpsichord, and organ, from the time of queen Elizabeth to the end of the seventeenth century, was written on a staff of six lines, both in the treble and the base. At the beginning of the last century, all music, except the tablature for the lute and guitar, began to be constantly written on and between five lines, called *spaces*, with the occasional use of short additional lines, for notes that go higher or lower than the regular staff. The lines and spaces in all music are counted from the bottom, so that the lowest is the first, the highest in canto fermo the fourth, and in figurative music the fifth. See STAVE, STAFF, PORTER, and RIGHE.

LINE, in *Inland Navigation*, is often used to express the principal part of a canal, and thus to distinguish it from its branches.

LINEs of *Deviation*, denote lines on the parliamentary plans of some canals, shewing the distances within a hill it is intended that the cutting of the canal should be continued.

LINE, *Geometrical*, in *Perspective*, is a right line drawn in any manner on the geometrical plane.

LINE, *Horizontal*. See HORIZONTAL.

LINE, *Terrestrial*, or *Fundamental Line*, is a right line, wherein the geometrical plane, and that of the picture, or draught, intersect one another.

Such is the line *NI* (*Plate I. Perspective, fig. 3.*) formed by the intersection of the geometrical plane *LM*, and the perspective plane *HL*.

LINE of the *Front*, is any right line parallel to the terrestrial line.

LINE, *Vertical*, is the common section of the vertical, and of the draught.

LINE, *Visual*, is the line, or ray, imagined to pass from the object to the eye.

LINE of *Station*, according to some writers, is the common section of the vertical and geometrical planes. Others mean by it, the perpendicular height of the eye above the geometrical plane; others, a line drawn on that plane, and perpendicular to the line expressing the height of the eye.

LINE, *Obj. line*, is any line drawn on the geometrical plane, whose representation is sought for in the draught or picture.

LINE of *Distance*. See DISTANCE.

LINEs on the *plain Scale*, in *Trigonometry*, are the line of chords, line of sines, line of tangents, line of secants, line of semi-tangents, line of leagues. The construction and application of these lines, see under SCALE, SAILING, &c.

LINEs on *Gunter's Scale*, are the line of numbers, line of artificial sines, line of artificial tangents, line of artificial versed sine, line of artificial lines of rhumbs, line of artificial tangents, of the meridian line, and line of equal parts. The construction and application of these lines, see under GUNTER'S SCALE.

LINEs of the *Sector*, are the line of equal parts, or line of lines; line of chords, line of sines, line of tangents, line of secants, line of polygons, line of numbers, line of hours, line of latitudes, line of meridians, line of metals, line of solids, line of planes; the construction and use of these, see SECTOR.

LINE, in the *Art of War*, is understood of the disposition of an army, ranged in order of battle; with the front extended as far as may be, that the several corps of cavalry and infantry which compose it, may not be cut off or flanked by the enemy.

An army usually consists of three lines; the *first* is the front, van, or advance-guard; the main body forms the *second*, in which is the general's post; the *third* is a reserved body, or rear-guard. The term *line*, as expressing a military arrangement for battle, was not known till the 16th century. Before that period, when armies were ranged in order of battle upon three lines, these several lines were denominated in the manner above stated; but the terms advance-guard, main body, and rear-guard, are never used in modern times, except when an army is on its march: when drawn up for action, or in the field for review, they are denominated *lines*.

The second line should be about three hundred paces behind the first, and the reserve at about five or six hundred paces behind the second.

The artillery is likewise distributed along the front of the first line. The front line should be stronger than the second, that its shock may be more violent, and that, by having a greater front, it may more easily close on the enemy's flanks.

Each line is so drawn up, that the wings or extremities always consist of some squadrons of horse, whose intervals are supported by infantry platoons. The battalions are posted in the centre of each line; sometimes they are intermixed with squadrons of horse, when a considerable body of cavalry is attached to the army. The space of ground which in each line separates the different corps from one another, is always equal in extent to the front that is occupied by them. These intervals are left in order to facilitate their several movements, and to enable them to charge the enemy without confusion. It is a general rule, that the intervals or spaces which are between each battalion and squadron belonging to the *second* line should invariably correspond with the ground that is occupied by the battalions and squadrons which constitute the *first* line; in order that the *first* line, on being forced to fall back, may find sufficient space to rally, and not endanger the disposition of the *second* line, by precipitately thronging and pressing upon it. Each line is divided into right and left wings; each wing is composed of one or more divisions; each division is composed of one or more brigades; and each brigade is formed of two, three, or four battalions. Battalions are formed in line at a distance of twelve paces from each other, and this interval is occupied by two cannon, which are attached to each battalion. For the difference between the Prussian and French mode of arrangement, and other particulars, see ARMY, BATTLE, COLUMN, ENGAGEMENT, and TACTICS.

The LINE is a term frequently used to distinguish the regular army of Great Britain from other establishments of a less military nature. All numbered, or marching regiments, are called *the line*. The guards are an exception to this rule. The marines, fencible, militia, volunteer, and yeomanry corps, together with the life-guards, are not comprehended under this denomination. The term *line*, however, has not been applied with sufficient precision and discrimination. Strictly speaking, *line*, in military matters, denotes that solid part of an army which is called the main body, and has a regular formation from right to left. Upon the whole, it may be observed, that the term is generally misapplied, and that it cannot, with strict propriety, be used to distinguish any particular establishment from another.

LINE, *To*, from the French *aligner*, is to dress any given body of men, so that every individual part shall be so disposed as to form collectively a straight continuity of points from centre to flanks.

LINE of March, denotes the orderly succession of the component parts of an army that is put in motion.

LINEs of March, are bodies of armed men marching in given points to arrive at any straight alignment on which they are to form. The line is said to be well *dressed*, when no part is out of the straight alignment. That this may be effected, at the word *dress*, which is given by the commander, it is immediately to commence from the centre of each battalion, the men looking to their own colours, and the correcting officers lining them upon the colours of their next adjoining battalion.

LINE-firings are executed separately and independently by each battalion.

LINE of Fire. See FIRE.

LINE, *To form the*, is to arrange the troops in order of battle, or battle array.

LINE, *Inversion of the*, is a manœuvre which is effected by facing a battalion or line to the right about, instead of changing its position by a countermarch; sometimes it may be necessary to form to a flank with its rear in front. The column, with its line in front, may arrive on the left of its ground, and be obliged immediately to form up and support that point, so that the right of the line will become the left. Part of a second line may double round on the extremity of a first line, thereby to outflank an enemy. These, and various other movements, may be found necessary, and they can only be practised with safety and expedition by the inversion of the line.

LINEs, *Retiring*, denote bodies of armed men that have advanced against an opposing enemy in order of battle, withdrawing themselves with regularity from the immediate scene of action. On this occasion, it is of the greatest moment, that the line should be correctly dressed before it faces to the right about; and the battalions will prepare for the retreat in the manner preferred for the single one, by receiving the caution, that "the line will retire."

LINEs of Support, are lines of attack, which are formed to support one another. If there are several, the second should outflank the first, the third the second, the advanced one being thereby strengthened and supported on its outward wing.

To LINE Men. Officers and non-commissioned officers are said to *line* the men belonging to their several battalions, divisions, or companies when they arrive at their dressing points, and receive the word *dress* from the commander of the whole. When a single battalion halts, it is dressed or lined on its right centre company, and must, of course, be in a straight line. When several battalions dress from the centre of each on its next colour, the general line will be straight, provided all the colours have halted regularly in a line. On these occasions, every thing will depend upon the two centre dresses of each battalion.

To LINE a Coast, under the immediate pressure of invasion, requires not any great ability and exertion in the commanding officer of the particular district against which an insult may be offered, but it is moreover necessary, that every individual officer in the different corps should minutely attend to the particular spot on which he may be stationed. The English coast, especially where there are bays, is almost always intersected by narrow passes through the rocks or sand-hills. On this account, when any body of men receives orders to line a specified extent of ground, the officers who are entrusted with the several parts of a battalion or

brigade, should take care to make the most of their men, and to extend their files in such a manner, as not only to present an imposing front from the crown of the hill, but to be able, at a moment's warning, to carry their whole strength to prevent the enemy from getting upon the flanks by suddenly rushing up the gap. Much coolness is required on these occasions.

To LINE Hedges, &c. to plant troops, artillery, or small arms, along them under their cover, to fire upon an enemy that advances openly, or to defend them from the horse, &c.

To LINE a Street or Road, is to draw up any number of men on each side of the street or road, and to face them inwards. This is frequently practised on days of ceremony, when some distinguished person is received with military honours on his way through places where troops are stationed.

LINE, *To break the*, is to change the direction from that of a straight line, in order to obtain a cross-fire.

LINE, *Turning out of the*. The line turns out without arms whenever the general commanding in chief comes along the front of the camp. When the line turns out, the private men are drawn up in a line with the bells-of-arms; the corporals on the right and left of their respective companies; the piequet forms behind the colours, with their accoutrements on, but without arms. The sergeants draw up one pace in the front of the men, dividing themselves equally. The officers draw up in ranks according to their commissions, in the front of the colours; two ensigns taking hold of the colours. The field-officers advance before the captains. The camp-colours on the flanks of the parade are to be struck, and planted opposite to the bells-of-arms; the officers' spontoons are to be placed between the colour, and the drums piled up behind them; the halberts are to be planted between and on each side the bells-of-arms, and the hatchets turned from the colours.

LINE, or *Line of Battle*, in *Naval Tactics*, is applied to the disposition of a fleet on the day of engagement; on which occasion the vessels are usually drawn up as much as possible, in a straight line, as well to gain and keep the advantage of the wind, as to run the same board. See ENGAGEMENT.

This right line, or long file, is prolonged from the keel of the hindmost to that of the foremost, and passes longitudinally through the keels of all the others, from the van to the rear; so that they are, according to the sea-phraze, in the wake of each other. In the line, or order of battle, all the ships of which it is composed are close hauled, upon the starboard or larboard tack, about fifty fathoms distant from each other. When a fleet is drawn up in line, in presence of an enemy, it should be formed in such a manner as that the ships may mutually sustain and reinforce each other, and yet preserve a sufficient space in their stations, to work or direct their movements with facility during the action. The line close-hauled is peculiarly chosen in the order of battle, because, if the fleet, which is to windward, were arranged in any other line, the enemy might gain the weather-gage of it; and even if he thinks it expedient to decline that advantage, it will yet be in his power to determine the distance between the adverse fleets in an engagement, and to compel the other to action. The fleet to leeward, being in a line close-hauled, parallel to the enemy, can more readily avail itself of a change of the wind, or of the neglect of its adversary, so as to get to windward of him; or, at least, so as to avoid coming to action, if the enemy is much superior, or to prevent him from escaping, if he should attempt it. Besides, in this order, the sails of each

each ship are so disposed as to counteract each other, and, therefore, the ships in general neither advance nor retreat during the action, and are thus enabled to keep their station, and to prosecute the battle with vigour, and without disorder. Whilst the uniformity of the line is preserved, the admiral's orders may be readily communicated by signals from the van to the rear; disabled ships may be more easily discovered and relieved; and the situation and circumstances of the enemy's line will be open to the view of the commander-in-chief. Moreover, the ships of the line should not only be sufficiently close to sustain each other, but they should be of the larger sort, with the weightier metal. Many advantages concur to recommend the larger ships in a line of battle; they overlook those of an inferior rate, which are accordingly laid open to the fire of their mucketry. In a high sea they can more safely employ the artillery of their lower deck than a smaller ship; and if both are obliged to shut their lower-deck ports, the advantage of the three-decked ships, with regard to their cannon, will yet be considerable; they have three tier against two, and two against one. The same superiority subsists, in case they are disabled, when the upper deck is incumbered with the ruins; the large ships, being higher between decks, are less incommoded with the smoke, and their cannon is managed with greater facility; the large ships, having greater solidity of frame, are better calculated to resist the effects of battle and tempest. In general also they sail better than the small ones, except in fine weather; for, in a fresh wind, when the sea becomes agitated, they have always the superiority. The fire-ships do not succeed so well against large ships as the smaller ones; the artillery will sink them, or oblige them sooner to relinquish their design; and they are easily towed away by the great long boats. The line of a fleet, which has many capital ships, need not be so much inclosed as that of an enemy which has fewer. The former may be also less numerous, without being weaker. This circumstance, however, should not exclude a certain number of the third and fourth rates, which are necessary in all naval armaments.

The weather-line and the line to leeward have their several advantages and inconveniences. The chief advantage of the former are, that it may approach the enemy, so as to determine the time and distance of the action; if it is more numerous than the lee-line, it may easily appoint a detachment to fall upon the van and rear of the latter, and inclose it between two fires; it is little incommoded by the fire or smoke of the cannon, and may dispatch the fire-ships, under cover of the smoke, upon the disabled ships of the lee line, or so as to oblige the enemy to break the line and bear away. But the weather-line has also its defects; when the sea is rough, and the wind boisterous, it cannot readily fight with the lower deck battery; it cannot decline the action without the dangerous expedient of forcing through the enemy's line; and if it keeps the wind, the lee-line may inclose and totally destroy it. The disabled ships of the weather-line must tack, to avoid falling into the enemy's fleet; and if they are much shattered, they may be altogether separated from their own fleet, particularly if they are in the rear of the line.

The advantages of the line to leeward are these: the ships of the former may use the guns of their lower decks, without the hazard of taking in such water at the ports in stormy weather, which the line to windward cannot do without great danger. The lee-line, though it cannot so easily double upon the van and rear of the enemy, and inclose them between two fires, may, nevertheless, have opportunities of tacking, and cutting off a part of the enemy's rear. The disabled ships to leeward are more easily removed from the

line than those to windward; and the lee-line can with greater facility avoid the action than its adversary, which is a circumstance very favourable to an inferior squadron. But the defects of the lee-line are, that it cannot decide the time and distance of the battle, which may commence before it is sufficiently formed; and it will, perhaps, be attacked by an enemy bearing down upon it in regular order. The fire and smoke of the weather-line are a great inconvenience to it; and it cannot easily break the enemy's line with its fire-ships, which are very slowly and with great difficulty conveyed to windward. The admiral's ship always preserves her station in the centre of the line. The line is said to be formed a-breast when the ships' sides are all parallel to each other, on a line which crosses their keels at right angles. This is most frequently used in pursuing or retreating, with the wind right aft, so that the line forms a perpendicular with the direction of the wind. Falconer's Mar. Dict.

The two modes of engagement by the line to windward and to leeward have been particularly illustrated; and also the method of cutting or breaking the line of battle, lately put in practice to great advantage, by John Clarke, Esq. of Eldin, in his "Essays on Naval Tactics;" a second edition of which was printed at Edinburgh in 1804, 4to. See TACTICS.

LINE is also a name given to several small cords of different sizes, and used for various purposes at sea. They are smaller than ropes, and formed of two or more fine strands of hemp; as *house-line*, made of three strands, used to seize blocks into their straps and the clews of sails, and to marl the skirts of sails to their belt-ropes; *log-line*, made of three or more strands, and used for the log, &c.; and *mar-line*, made of two strands, and used for the same purposes as house-line. Some ropes are, from their situation, termed lines, as *bow-lines*, *ban-lines*, *chue* or *clew-lines*, *Fancy-line*, which is a rope used to over-haul the brails of some fore and aft sails; *furling-lines*, *girt-lines*, *head-lines*, *keech-lines*, which are ropes used to truss up the sails; *life-lines*, for the preservation of the seamen, which are worn hawser-laid rope, and made fast with two half-hitches round the strap of the lift-block, and jeer or tye-blocks in the middle of the yard; *naue line*, *slab-line*, *spilling-lines*, *tow line*, and *tracing-lines*; which see respectively.

LINE, *Ship of the*, is a vessel large enough to be drawn up in the line, and to have a place in a sea-fight. See SHIP.

LINE, *Knave*, in a Ship. See KNAVE.

LINE of Measures, is used by Oughtred to denote the diameter of the primitive circle in the projection of the sphere in plano, or that line in which the diameter of any circle to be projected falls.

In the stereographic projection of the sphere in plano, the line of measures is that line in which the plane of a great circle, perpendicular to the plane of the projection, and that oblique circle which is to be projected, intersects the plane of the projection; or it is the common section of a plane, passing through the eye-point and the centre of the primitive; and at right angles to any oblique circle which is to be projected, and in which the centre and pole of such circle will be found.

LINE, *Measure of a*. See MEASURE.

LINE of Demarcation, or *Alexandrian Line*, is a meridian passing over the mouth of the river Maragnon, and by the capes of Honna, and Malabrigo; so called from pope Alexander VI. who, to end the disputes between the crowns of Castile and Portugal about their boundaries, in 1493, drew an imaginary line on the globe, which was to terminate the pretensions of each. By which partition the East Indies

fell to the lot of the Portuguese; and the West Indies, then newly discovered, to the Caribians.

LINE, Bowling, Bunt, Crow, Furlong, Log, Rhumb, and Water; see under the respective adjectives.

LINE also denotes a small French measure, containing the 12th part of an inch, or 144th part of a foot.

The geometers, notwithstanding its smallness, conceive the line subdivided into six points.

The French line answers to the English barley-corn.

LINE, Angling. The best materials for making these lines are fine and even horse-hairs; the hair should be round and twisted even, for that greatly strengthens it; and all the hairs should be of an equal bigness, or as nearly so as may be. They should be laid in the water about a quarter of an hour after twisting, that it may be seen which will shrink; they are then to be twisted over again. In this last twisting some intermingle silk among them, but that is not so well. Lines made entirely of silk are not bad; but those of silk and hair mixed are never found to do well. The best colours for a line are forrel, white, and grey; the two last are best for angling in clear waters; the former in muddy ones. The pale watery-green is also a very good colour, and may be made thus: boil in a quart of alum-water a large handful of marygold-flowers; there will arise a scum which must be taken off; then add to this liquor copperas and verdigris, of each half a pound, beat to powder together; boil these up together; then put the hair into this liquor, and let it lie ten or twelve hours; it will obtain a watery blueish green colour, which will not wash out afterwards.

LINE of Equat.d Bodies. See *EQUATED BODIES*.

LINES, Gauge, Plum, and Rear. See the several adjectives.

LINE White, in Printing. See *WHITE*.

LINEA ALBA, in Anatomy, is a white line in the abdomen, formed by the union of the tendons of the abdominal muscles. See *OBLIQUUS externus abdominis*.

LINEA Mediana. See *MEDIANA*.

LINEA Nubosa. See *NEBULOSA Linea*.

LINEA Seminalis, is a line following the outer edge of the *RECTUS abdominis* muscle; which see.

LINEÆ Transversæ, lines crossing the rectus abdominis. See *RECTUS*.

LINEAL DESCENT. See *DESCENT*.

LINEAL Exegesis. See *EXEGESIS*.

LINEAMENT, a fine stroke or line observed in the face, and forming the delicacy thereof; being that which preserves the resemblance, and occasions the relation of likeness, or unlikeness, to any other face.

It is by these that physiognomists pretend to judge of the temper and manners of people.

LINEAMENT is also used by the painters for the outline of a face. See *CONTOUR*.

LINEANS PUNCTUM. See *PUNCTUM*.

LINEAR LEAF. See *LEAF*.

LINEAR Numbers, are such as have relation to length only. See *NUMBER*.

Such *e. gr.* is a number which represents one side of a plane figure. If the plane figure be a square, the linear number is called a *root*.

LINEAR Problem, in Mathematics, is that which may be solved geometrically, by the intersection of two right lines. *E. gr.* to measure an inaccessible height by the means of two unequal sticks, &c.

This is also called a *simple problem*, and is capable but of one solution.

LINEATORES, in the Hippodrome at Constantinople, were the same with the *designatores* in the Circus at Rome. See *HIPPODROME*, *CIRCUS*, and *DESIGNATOR*.

LINEN, in *Geography*, a town of Germany, in the county of Tecklenburg; 7 miles S.S.E. of Tecklenburg.

LINEN, in the *Manufactures*. There are various sorts of linen, the principal materials of which are cotton, flax, and hemp. The linen trade of Europe is chiefly in the hands of the Russians, Germans, Swits, Flemings, Hollanders, and French.

Linen is the staple of Ireland, as it was of Scotland; but it was long neglected. The Scots at present are not, however, in so bad a situation in respect to this trade, as the French were in the reign of king Henry IV. or the Irish at the Revolution; where, by the force of public encouragement, it has arrived to an extraordinary pitch, and it is to be hoped will daily advance: the Scots have it not to begin, and they are improving and extending it to a very great degree.

The balance of trade between England and Scotland, and England and Ireland, is on the English side; and so far as England and its dependencies can be served with linen from Scotland and Ireland, instead of Holland, France, Germany, and Russia, so far will England be a gainer by this change in the course of trade. The more linen the Scots and Irish can sell in England, the more of the English commodities will they be able to purchase; and it may be reasonably supposed that their demands from England will always increase in proportion to the increase of their people and linen manufactures. It is then evidently the interest of England to promote and advance the manufacture of linen in Scotland and Ireland, and to give them all reasonable advantages in the trade, in preference to foreigners; where the balance of trade is against us, and this seems to be the sense of the nation, since all foreign linen, for home consumption, pays a duty. Post. Dict. Com.

The linen trade of this country is regulated by several statutes.

No person shall put to sale any piece of dowlas linen, &c. unless the just length be expressed thereon, on pain of forfeiting the same. (28 Hen. VIII. cap. 4.) Using means whereby linen-cloth shall be made deceitfully, incurs a forfeiture of the linen, and a month's imprisonment. (Stat. 1 Eliz. cap. 12.) Any persons may set up trades for dressing hemp or flax, and making thread for linen-cloth, &c. 15 Car. II. cap. 15.

By the 43 Geo. III. c. 69. all former duties on linen cloth, silks, cottons, and calicoes, are repealed; and in lieu thereof other duties are imposed upon all goods which shall be printed, stained, painted, or dyed in Great Britain, according to a schedule annexed to the act; and by 50 Geo. III. c. 26. certain export duties are imposed; the said duties to be paid by the printer, raiser, painter, or dyer. By 49 Geo. III. c. 98. certain duties and customs are imposed upon French linens, (or lawns.) By 43 Geo. III. c. 69. every calico printer, and every printer, painter, or raiser of linens, cottons, or stuffs, shall pay annually for a licence 10*l.* The printing or staining of calicoes must be for exportation; because by 7 Geo. II. c. 7. the use of printed, painted, stained, or dyed calico for wearing apparel is prohibited, on pain of 5*l.* to the informer, on conviction: and a person offering such for sale, unless for exportation, forfeits 20*l.* half to the informer, and half to the poor. This prohibition, however, does not extend to calicoes dyed wholly blue: and it shall be lawful to use stuff made of linen yarn and cotton wool manufactured, and printed or painted in Great Britain, provided the warp thereof be wholly linen yarn.

yarn (9 Geo. II. c. 4.) By 14 Geo. III. c. 72. it is enacted that no greater duty shall be paid for stuffs made of raw cotton wool within this kingdom than $3\frac{1}{2}d.$ a yard, 43 Geo. III. c. 69. and that any person may use the same in apparel or otherwise: and every piece is to have three blue stripes in both selvages, and to be stamped at each end with a stamp provided by the officers of excise, and instead of the word *calico*, used for foreign calicoes, each piece shall be marked with the words *British Manufactory*. If stuffs made wholly of cotton, and printed, painted, stained, or dyed stuffs, (mullins, neckcloths, and fustians excepted,) without such mark shall be exposed to sale, they shall be forfeited, and 50*l.* for each piece. If any person shall counterfeit such stamp, or knowingly sell such stuffs with a counterfeit stamp, he shall be guilty of felony without benefit of clergy. If any person shall import any calicoes, mullins, or other stuffs made of linen yarn only, or of linen yarn and cotton wool mixed, or wholly of cotton wool, in which shall be wove in the selvedge any such blue stripe, he shall forfeit the same, and 10*l.* for each piece. Every such printer, painter, stainer, or dyer, shall give notice in writing, at the next office, of his name and place of abode, and where he intends to work, on pain of 50*l.* (10 Anne, c. 19. 25 Geo. III. c. 72.) By 1 Geo. II. c. 34. any person, undertaking to print, paint, &c. any silks, linens, or stuffs, at any other place than the place of his usual residence or exercise of his trade, shall first make entry of the place, and pay the duties, on pain of 50*l.*, and forfeiture of the goods. Officers may enter at all times by day or night to take account, &c. and the penalty of obstructing the officer in the execution of his duty is 200*l.* (10 Anne, c. 19. 25 Geo. III. c. 72.) Goods shall be entered once in six weeks on oath before the collector or supervisor, on pain of 50*l.* (10 Anne, c. 19.) No person shall begin to print, stain, paint, or dye any goods before they have been measured and marked, on pain of forfeiting the same, and also 20*l.* for every piece. (25 Geo. III. c. 72.) If any printer shall wilfully cut out or deface such frame mark, he shall forfeit 50*l.* Concealing goods, or avoiding duty, incurs a forfeiture of 50*l.*: and all goods found in a place, of which no notice has been given, or the value thereof, shall be forfeited. (10 Anne, c. 19. 25 Geo. III. c. 72.) Nor shall goods be kept in unentered places on pain of forfeiting 50*l.* and the goods. 20 Geo. III. c. 72.) Within six weeks the duties shall be cleared, on pain of forfeiting double. (10 Anne, c. 19.) Nor shall they be removed before the officer hath taken account of them and stamped them, on pain of 50*l.* and seizure. (10 Anne, c. 19. 25 Geo. III. c. 72.) Goods surveyed shall be kept separate from those unsurveyed, on pain of 50*l.*: and goods untamped may be searched for and seized. (10 Anne, c. 19. 25 Geo. III. c. 72.) The person in whose custody such goods are found shall forfeit 100*l.* 5 Geo. c. 11. 27 Geo. III. c. 31.

Calicoes, &c. that shall not have three blue threads in the selvedge, shall be deemed foreign calicoes, and on being printed or dyed, shall be marked at each end with the words "for 12*l.* calicoes for exportation;" and every dealer who shall have any such goods in his custody (except dyed throughout of one colour) or any stuffs made wholly of cotton wool wove in Great Britain, commonly called "British Manufactory," (mullins, neckcloths, and fustians excepted,) not having such blue threads, shall forfeit 200*l.* and every such piece found in his custody. (25 Geo. III. c. 72.) The owner or printer of any piece or remnant of calicoe or foreign mullins and calicoes shall, before they be presented to the officer, mark the same at both ends with a frame mark, containing his name and place of abode, and

also the name by which such goods are commonly known (except such as are dyed throughout of one colour) on pain of forfeiting 10*l.* for every piece or remnant. The owner or printer of any linens or stuffs made of cotton mixed, or wholly of cotton wool wove in Great Britain, called "British Manufactory or Mullins," shall mark the same at both ends (fustians, velvets, velverets, dimities, and other figured stuffs excepted) with a mark, containing his name and place of abode, and the name and quality of such goods, with the ready money price thereof, before the same are presented to the officer in order to be printed or dyed: on pain of forfeiture and seizure, and 20*l.*; and if any such piece be marked at a less price than the real value, the same may be seized and forfeited, and the owner shall forfeit 20*l.* If the frame mark be defaced, the same shall be renewed on notice; but if any person shall counterfeit or forge any frame mark, he shall forfeit 100*l.*: and if any person counterfeit the stamp, it is felony without benefit of clergy. (25 Geo. III. c. 72. 27 Geo. III. c. 31.) If any person shall knowingly sell any of the goods with a counterfeit stamp, he shall forfeit 100*l.* and stand two hours in the pillory. (10 Anne, c. 19. 13 Geo. III. c. 56. 25 Geo. III. c. 72.) By 27 Geo. III. c. 31. if any person shall knowingly sell any such goods with counterfeit stamp, thus intending to defraud his majesty, he shall be guilty of felony without benefit of clergy. Every person who hath paid the duties, or bought the goods of any person who hath paid the duties, may export the same, and shall be allowed all the duties in drawback, as set forth in 43 Geo. III. c. 69. Sched. C. on conforming to certain prescribed conditions. (25 Geo. III. c. 72. 25 Geo. III. c. 74.) By the 4 Geo. III. c. 37. which establishes the corporation of the English Linen Company for making cambrics and lawns, it is enacted that the commissioners of excise, where there shall be a manufactory of cambrics or lawns, or of goods known under that denomination, shall appoint the supervisor or other officer to seal the same, for which they shall have such fee as the commissioners shall appoint: the manufacturer to give notice in writing to the officer, of the finishing of every piece, before it is taken out of the loom, who shall seal the same at both ends; on pain that such manufacturer, taking the same out of the loom without having given such notice, and having the same sealed as aforesaid, shall forfeit 5*l.*; and every such piece shall be forfeited, and may be seized by any officer of the customs or excise, and the officer, with convenient speed after notice, shall mark and also number each piece; and make entry in writing, in books to be provided at the expence of the manufacturer, of the number set to each piece, the length thereof, and the number of threads in the warp, on pain of 10*l.* If the officer shall mark any not made in England, or after the same is taken out of the looms, he shall forfeit 50*l.* for each piece to him who shall sue, and forfeit his office, and be incapacitated to hold any other office of trust under the crown. If any person shall offer to the officer any bribe, he shall forfeit 50*l.*; and if he shall by bribery, or otherwise, prevail upon the officer to commit such offence, he shall forfeit 100*l.*, and stand in the pillory two hours. And the officer shall yearly, in the month of June, transmit to the commissioners an account of all goods which he shall have stamped, and a copy of the entries made, on pain of dismissal; and he, or his executors, shall deliver up the seals, on demand from the commissioners, on pain of 200*l.* Cambrics and lawns made in England found untamped, shall be forfeited, and may be seized by any officer of the customs or excise, and after condemnation shall be sold; and every person who shall sell or expose to sale, or have in his custody for

for that purpose, any cambrics or lawns made in England, unmarked, shall forfeit 200*l.* such goods not to be sold, or worn in this kingdom, but to be exported, and to be sold only on condition of exportation. Nor shall they be delivered out of the warehouse until bond be given, to the satisfaction of the collector, in double penalty of the goods, that the same shall be exported, and not re-landed. To counterfeit the seal appointed by this act, or import any foreign cambrics or lawns having such counterfeit mark thereon, or expose the same to sale, knowing the stamp thereon to be counterfeited, is felony without benefit of clergy. All goods condemned in pursuance of this act, and all pecuniary forfeitures not otherwise directed shall be paid for and recovered in any of his majesty's courts, in the name of the attorney-general, or of such officer as afore said; and applied, after deduction of charges, half to the king, and half to the officer seizing, in writing, or suing, according to the directions of this act. The penalties may be sued for, levied, and enforced as by the laws of excise, or in the courts at Westminster; and employed half to the king, and half to him that shall deliver, inform, or sue. (10 Anne, c. 19. 24 Geo. II. c. 40. 25 Geo. III. c. 72.) All utensils and instruments for printing, painting, staining, or dyeing such goods, in custody of the said person, or any other, shall be liable to all arrears of the duty, and to all penalties concerning the same, in like manner as if such person was the lawful owner. 10 Anne, c. 19. 25 Geo. III. c. 72. 28 Geo. III. c. 37.

Stealing of linen, stuffs, cotton goods, &c. from whitening-houses or drying houses, to the value of 10*l.* or knowingly buying or receiving such stolen goods, is felony without benefit of clergy. (18 Geo. II. cap. 27.) Such also is breaking into houses, shops, &c. and destroying any linen cloth, or implements used in the manufacturing of it, by 4 Geo. III. cap. 37. See LARCENY.

A new manufacture was set on foot some time ago in London, for embellishing linen with flowers and other ornaments of gold leaf. The linen looks whiter than most of the printed linens; the gold is extremely beautiful, and is said to bear washing well. See STEFF.

There are many substances from which a juice or dye is obtained, that will stain linen of different colours. The juice of the anacardium, rubbed on linen or cotton, gives a reddish-brown stain, which soon deepens in the air into a black, and which has not been discharged by washing and boiling, with soap or alkaline ley. Hence the anacardium is said to be used for marking linen and cotton cloths, and to be known all over India by the name of marking-nut. The juice of the cashew-nut, called by some the anacardium of the West Indies, differs from the oriental anacardium in its coloring quality; that lodged between its fibres being such a pale, and giving to linen, cotton, or paper, only a brownish stain, which is durable, but does not change at all towards blackness.

Several species of the toxicodendron, or poison-wood, contain in their leaves a milky juice, which in drying becomes of a deep black, and communicates the same colour to the linen on which it is dropped: the linen thus stained, boiled with soap, came out without the least diminution of its colour, nor does strong ley of wood-ashes make any change in it. Phil. Transf. vol. xlix. for 1755.

Dr. Lewis has found, that the milks of wild poppies, garden poppies, dandelion, hawk-weed, and fow-thistle, gave brown or brownish-red stains, which were discharged by washing with soap; the colourless juice which issues from hop-stalks when cut, stains linen of a pale reddish or brownish-red, extremely durable: the juice of flues gave

likewise a pale brownish stain, which, by repeated washings with soap, and wetting with strong solution of alkaline salt, was darkened to a deeper brown; on baking the flues, their juice turns red, and the red stain which it then imparts to linen is, on washing with soap, changed to a pale blueish, which also proves durable. See DYEING of Thread.

The late Dr. Samille has recommended the following method of marking linen, so as not to wash out again: take vermilion, as much as will lie on a half-crown piece, of the felt of steel a piece about the size of a small money; grind or levigate them well together with hand oil: the composition may be diluted or thinned at pleasure.

LINEN, *Fossil*. See AMIANTHUS and ASBESTOS.

LINEN, *Milk*. See MILK.

LINEN, *White*. See WHITE.

LINEN, *Bleaching of*. See BLEACHING.

LIN-FOU, in *Geography*, a town of Corea; 20 miles S. of Haima.

LING, in *Agriculture*, a provincial term applied to the plant usually known by the name of *HEATH*.

By 4 & 5 W. c. 23. no person shall do any new drains, hills, heaths, moors, forests or chases, or other wastes, burn between February 2, and June 24, any grass, ling, heath, furze, gois or fern, on pain of being committed to the house of correction, for any time not exceeding one month, nor less than 10 days, then to be whipped and kept to hard labour.

LING, in *Ichthyology*, the English name for a kind of fish, which is a species of the genus, with two fins on the back, with a bearded mouth, and with the upper jaw longest. See GALT'S *Moine*.

Ling is eaten raw, both fresh and cured, for the table.

This fish abounds about the Scilly isles, on the coasts of Scarborough, and those of Scotland and Ireland, and forms a considerable article of commerce. In the Yorkshire seas they are in perfection from the beginning of February to the beginning of May, and some till the end of that month. They spawn in June, at which time the males separate from the females. When the ling is in season, its liver is very white, and abounds with a fine floured oil, which afterwards becomes red, like that of a bullock, and affords no oil. This oil is said to be hoarded up in the cellular membranes of fishes, to return into their blood, and support them in the engendering season. Great quantities of this fish are salted for exportation, and for home-consumption: for this purpose it must measure twenty-six inches or upwards from the shoulder to the tail, in order to be entitled to the bounty on exportation. Those under that size are called *dreadles*. Pennant.

LINGA, in *Geography*, one of the smaller Swedish islands, near the N. coast of Mainland. N. lat. 60° 44'. W. long. 1° 27'.—ALFO, one of the same group of islands near the E. coast of Mainland. N. lat. 60° 34'. W. long. 1° 6'.—ALFO, one of the same cluster, near the S.W. coast of Unit. N. lat. 61° 2'. W. long. 1° 12'.—AISO, one of the small western islands of Scotland, near the S. coast of South Uth. N. lat. 57° 5'. W. long. 7° 14'.

LINGA Sound, a bay on the W. coast of the Island of Stronsa. N. lat. 59°. E. long. 0° 28'.

LINGA, or *Lizum*, as it is pronounced in the southern and eastern parts of the peninsula, in *Hindoo Mythology*, is a symbol to which great veneration is paid, and much mysticism attached, by the extensive sect of Hindoos called Saivas, or the worshippers of Siva, the destructive, or rather regenerative power of their god. This type of Siva is represented of a conical form, and is seen in almost all parts of India, of various sizes, in stone, wood, clay, metals, &c.

It may be supposed that Siva, being, among his other attributes, a personification of fire, as the most destructive of elements, was typified by a cone with its apex upwards, the form naturally assumed by flame; and that to this form enthusiasts have, in the wildness of their imagination, fancied allusions, and directed analogies, that, in the progress of time, have more and more bewildered them: until at length such an inextricable mass of mysticism hath been accumulated referring to this symbol, as to wear an appearance almost of ridicule. The Linga being the symbol of Siva, his votaries are reminded of it, and of its archetype by any thing conical or erect; a hill, a tree, any pyramidal object, a mast or pole, &c. Lingas are seen of enormous size; in the cavern of Elephanta for instance, marking unequivocally that the symbol in question is at any rate as ancient as that temple, as they are of the same rock as the temple itself; both, as well as the floor, roof, pillars, pilastres, and its numerous sculptured figures, having been once one undistinguished mass of granite, which excavated, chiselled, and polished, produced the fire cavern, and forms that are still contemplated with so much surprise and admiration. The magnitude of the cones, too, further preclude the idea of subsequent introduction, and together with gigantic statues of Siva and his consort, more frequent and more colossal than those of any other deity, necessarily, as before noticed, coeval with the excavation, indicate his paramount adoration, and the antiquity of his sect. (See ELEPHANTA and KARLY.) Lingas are seen also of diminutive size for domestic adoration, or for personal use: some individuals always carrying one about with them, and in some Pradhan families one is daily constructed in clay, placed, after due sanctification by appropriate ceremonies and prayers, in the domestic shrine, or under a tree or shrub sacred to Siva, the Bilva (*Cratæva marmelos*) more especially, and honoured by the adoration of the females of the household. This ceremony is called *Linga-puja*, i. e. the worship of the Linga, a beautiful plate of which, with a particular description, is given in Moor's *Hindu Pantheon*, where "a pious female is represented in plate 22, propitiating Mahadeva (another name of Siva) in his generative character, indicated by the Linga, inserted in its appropriate receptacle the *Argha*, or *Yoni*, mysterious types of nature, particularly discussed in future pages. The devout female may be imagined as invoking the deities, typified by their symbols, for the blessing of fruitfulness, its reverse being deprecated by both sexes, as the most afflictive visitation of divine displeasure. It is explained hereafter, how certain ceremonies called *Sradha*, to be performed by the offspring of deceased parents, are essential to the repose of a departed soul." P. 68. See *SRADHA*, *YONI*, and *MERU*.

A sect of Hindoos worship almost exclusively the Linga, as the symbol of their deity: this sect is called *Lingaja*, *Lingancita*, and *Lingi*. Another sect, exclusive worshippers of the *Yoni*, or the female power, are called *Yonija*; the former being apparently the same as the Phallic emblem of the Greeks, the *membrum virile*; and the latter *puendum muliebre*, rarely, however, seen in India in an indecent form. "The mystery in which the real history of these emblems is veiled, renders it extremely difficult to give a clear account of the origin or tendency of the rites by which we see their votaries honour them. That they had their origin in nature and innocence we may admit, without admitting likewise the propriety of their continuance to a period when nature and innocence are no longer seen unobscured: knowing, however, so little of the genuine history of these rites and symbols, it is but a reasonable extension of charity to suppose that their origin was philosophical though my-

sterious, and that their observance, though offensive to delicacy, is not criminal.

"It is some comparative and negative praise to the Hindoos, that the emblems under which they exhibit the elements and operations of nature, are not externally indecorous. Unlike the abominable realities of Egypt and Greece, we see the Phallic emblem in the Hindoo exhibitions without offence; and know not, until the information be extorted, that we are contemplating a symbol, whose prototype is obscene. The plates of this work may be turned and examined over and over, and the uninformed observer will not be aware that in several of them he has viewed the typical representation of the generative organs or powers of humanity. The external decency of the symbols, and the difficulty with which their recondite allusions are discovered, both offer evidence favourable to the moral delicacy of the Hindoo character. I am not, however, prepared to deny the appearance, in many instances, of strong evidence to the contrary; the disgusting faithfulness of natural delineations, and the combinations so degrading to human nature, observable on some of the temples and sacred equipages of the Hindoos, are deeply offensive to common delicacy and decency; and I continue of opinion that such objects of depravity, publicly offered to juvenile contemplation, cannot fail of exciting in such untutored, especially female, minds, ideas obnoxious to the innocence that we love to think an inmate there." (*Hin. Pan.* p. 382.) Something on this topic, and an instance of the adoration of the Linga in a magnificent temple, occur under the articles *IDOLATRY* and *JERY*. See also *PHALLUS*. The similarity of Phallic and of Linga worship, and other Grecian, Egyptian, and Hindoo coincidences, are learnedly discussed by major Wilford in the third, fourth, sixth, and eighth volumes of the *Asiatic Researches*. See *GENTOOS* and *LOTOS*, in this work.

LINGAJA, a sect of Hindoos, who adore, it is said, exclusively, the Linga, a symbol of Siva. See *LINGA*, and *SECTS of Hindoos*.

LINGAN, in *Geography*, a river of Ireland, which runs into the Suir; 2 miles below Carrick-upon-Suir.

LINGANCITA, a sect of Hindoos, the same with *Lingaja*, who exclusively worship Siva under the symbol of a Linga or Phallus. See *LINGA*, and *SECTS of Hindoos*.

LINGAPOUR, in *Geography*, a town of Hindoostan, in Dowlatabad; 15 miles S. of Nurmul.

LINGAY, one of the smaller western islands of Scotland, near the S.W. coast of Harris. N. lat. 57° 40'. W. long. 7°.

LING-CHAN, a town of Corea; 76 miles E.N.E. of Han-tcheon.

LINGEN, a city of Westphalia, and capital of a county of the same name; formerly fortified, but now barely surrounded with a ditch, and small. It is the seat of the regency of the united counties of Linggen and Tecklenburg, and of the deputations of the war and domain chamber of Minden, and has a Calvinist, a Lutheran, and a Roman Catholic church. The academical gymnasium of this place was founded in 1697 by William III., prince of Orange. About a quarter of a mile distance from the town, N. of it, is the passage over the Embs, called the "Lingen Ferry." —Also, a county of Westphalia, bounded on the N. by the bishopric of Munster, on the E. by the bishopric of Osnabruck, on the S. by the county of Tecklenburg, and on the W. by Bentheim. At the peace of Tilsit it was ceded by Prussia to Westphalia. It has mines of coal and quarries of stone. The chief town of the upper division of the county is Linggen, and that of the lower Ibbenbühren.—Also, an island

island in the East Indian sea, near the S. coast of Malacca, about 100 miles in circumference, and 50 miles from the N.E. coast of the island of Sumatra. S. lat. $0^{\circ} 10'$. E. long. $104^{\circ} 40'$.

LINGENDES, CLAUDE DE, in *Biography*, a French Jesuit, and one of the most celebrated preachers of the period in which he flourished, was born at Moulins in the year 1591. He entered the order when he was sixteen years of age, and after completing his studies to the satisfaction of his superiors, became eminent as an instructor in rhetoric and polite literature. His chief talent was soon discovered by the eloquence of his pulpit discourses, and for six and thirty years he attracted crowded audiences by the excellence of his compositions, and by his fine elocution. Besides the labours of the pulpit, he presided eleven years over the college of his native place, and afterwards filled the post of provincial of the order in France. He died in 1660, at the age of sixty-nine, while he was superior of the Jesuits' seminary at Paris. He was author of a popular work, entitled "Monita quedam ad Vitam bene Ordinandam," which has been frequently reprinted: "Votivum Monumentum ab Urbe Molinensi, Delphino oblatum;" and of Latin sermons, entitled, "Concionum quadragesimalium Argumenta," which have been published in 4to. and 8vo. and which have been translated into the French language, and much read in the original and translation. Gen. Biog.

LINGHOLM, in *Geography*, a small island among the Orkneys, near the W. coast of Stronfa. N. lat. $50^{\circ} 59'$. E. long. $0^{\circ} 27'$.

LINGI, a sect of Hindoos, worshippers of the Linga, a Phallic emblem of Siva, the destructive and regenerative power of the Indian triad. See LINGA, SECTS of Hindoos, and SIVA.

LINGICOTTA, in *Geography*, a town of Africa, in Kullo. N. lat. $12^{\circ} 30'$. W. long. $9^{\circ} 10'$.

LINGLEBACH, JOHN, in *Biography*, a painter of grotesque subjects, fairs, mountebanks, landscapes, &c.; born at Frankfort on the Maine in 1625; who having early acquired some knowledge of the art of painting, went to Rome for his improvement, but returned to his native country at the age of 25, to practise in his own native style. He did indeed acquire in Italy a slight taste for the classic, which he exhibited by introducing splendid ruins sometimes in his landscapes; but in general his taste is Dutch, and his style also, particularly in colouring and effect. His pictures are in general pleasing, having very much the tone of those of Adrian Vandewelt, though not finished so minutely, and indeed differing in choice of subject. He was frequently employed by eminent artists to insert figures and animals in their landscapes; and his ingenuity in the management of his pencil, enabled him so to assimilate his touch to that of the painter who employed him, that it is not easy to discover his hand. He died in 1687, at the age of 62.

LING-NGAN, in *Geography*, a city of China, of the first rank, in Yun-nan. N. lat. $23^{\circ} 38'$. E. long. $102^{\circ} 42'$.

LINGNIANY, a town of Lithuania; 32 miles E. of Wukomierz.

LINGONES, in *Ancient Geography*, a people of Gallia Cisalpina, near the Po, and north of the Boii, in the northern part of Bolognese and in Ferrara. They formed leagues of amity with the Boii, and, like them, they were Gauls in their origin; and their descent has been traced by some authors from the Lingones of Gallia Transalpina, where they inhabited a territory near the present Langres. Their towns in Italy were Forum Corneli, Claterna, Faventia, Solonæ, and Batrium. Traces of the same people have been also discovered in Upper Germany.

LING-QUAN-Y, in *Geography*, a town of China, in the province of Chen-li; 50 miles S.W. of Si-ngan.

LING-TAO, a town of China, of the first rank, in Chen-li, situated on the Tie-tan river, which falls into the Hoang-ho, or Yellow river. Gold is found in great quantities in the sand of the neighbouring rivers and brooks. The country is very mountainous, and abounds with wild bulls, and an animal resembling a tyger, whose skins are very valuable. The vallies are fertile in corn, and the pastures near the rivers supply food for cattle. Upon this city depend two cities of the second class, and three of the third. N. lat. $25^{\circ} 22'$. E. long. $106^{\circ} 34'$.

LING-TCHEOU, a town of Corea; 28 miles S.S.W. of Koang-tcheou.

LINGUA GROSSA, a town of Sicily, in the valley of Demona; 9 miles W. of Taormina.

LINGUA, Tongue, in *Anatomy*. See DEGLUTITION and TONGUE.

LINGUA Avis, Bird's-tongue, in the *Materia Medica*, the seed of the ash-tree, or ashen-keys.

LINGUA Cervina, in *Botany*, Hart's Tongue, a species, or with Plumier, Tournefort, and others, a genus of the fern tribe. See ASPLENIUM and SCOLOPENDRIUM.

LINGUA Medica, in *Laws*. See MEDIETAS.

LINGUE FRÆNUM, in *Anatomy and Surgery*. See FRÆNUM.

LINGUADO, in *Ichthyology*, the name of a West Indian fish, in shape resembling a toad.

LINGUALIS, in *Anatomy*, an epithet applied to some parts about the tongue. The lingual artery is a large branch of the external carotid. (See ARTERY.) For the lingual glands, see DEGLUTITION; for the lingualis muscle, see DEGLUTITION; and for the lingual nerve, see NERVE.

LINGUATULA, in *Ichthyology*, a species of *pleuronectes*; which see.

LINGUATULA, in *Natural History*, a genus of the vermes mollusca class and order: body depressed, oblong; mouth placed before, surrounded with four passages. Of this genus there is but a single species; viz. the *Serrata*, which inhabits the lungs of a hare.

LINGULA, in *Ichthyology*, the name of an extremely small fish of the foal-kind. It is known from the rest of this genus not only by its smallness, but by a ridge of small scales, which run along the line over the spine, and are much more elevated and distinguishable, both to the eye and touch, than those of the rest of the body. It is a well-tailed fish, and much firmer in its flesh than the foal, but is very scarce, and is of little value, because of its thinness. It is caught in the Mediterranean.

LINGULACA, a name by which several authors, particularly some of the older naturalists, have called the *foal fish*.

LINGULATUM FOLIUM, in *Botany*. See LEAF.

LINGUMPILLY, in *Geography*, a town of Hindoostan, in Mysore; 30 miles S.W. of Tadameri.

LINHARES, a town of Portugal, in the province of Tras los Montes; 19 miles S. of Miranda. — Also, a town of Portugal, in the province of Beira; 5 miles S.W. of Calorico.

LINHAY, in *Rural Economy*, a provincial word applied in Devonshire to signify an open field.

LINIERES, LA, in *Geography*, a town of France, in the department of the Charente; 15 miles S.W. of Angoulême.

LINIMENT, LINIMENTUM, from the Latin *linire*, to anoint gently, in *Pharmacy*, a form of external medicine, made

made of unctuous substances, used to rub on any disordered part.

The liniment is of a mean consistence between an oil and an unguent.

The use of liniments is to soften asperities of the skin, moisten parts that need humectation, and resolve the humours that afflict the patient and give him pain. There are various kinds of liniments used, according to the various occasions.

LINIMENTUM ALBUM, P. L. 1745; *Unguentum spermaceti*, P. L. 1787; *Unguentum cetacci*, P. L. 1809, ointment of spermaceti, is formed as follows: take oil-olive three ounces, spermaceti six drachms, white wax two drachms; melt all together over a gentle fire, stirring it till it is perfectly cold.

This liniment may be applied in cases of excoriation, where, on account of the largeness of the surface, the ointment with lead or calamine might be improper.

LINIMENTUM ERUGINIS, *Liniment of Verdigris*, P. L. 1809; *Unguentum Aegyptiacum*, P. L. 1720; *Mel Aegyptiacum*, P. L. 1745; *Oxymel eruginis*, P. L. 1787, is prepared by dissolving an ounce of powdered verdigris in seven fluid-ounces of vinegar, and straining it through a linen cloth; then adding gradually fourteen ounces of clarified honey, boil it down to a proper consistence. This preparation is intended only for external use.

LINIMENTUM AMMONIÆ Fortius, *strong liniment of ammonia*, is formed by shaking together a fluid-ounce of solution of ammonia, with two fluid-ounces of olive oil, until they unite.

LINIMENTUM AMMONIÆ Carbonatis. See **LINIMENTUM Volatile**.

LINIMENTUM ARESII, P. L. 1720; *Unguentum e gummi elemi*, P. L. 1745; *Unguentum elemi compositum*, P. L. 1787, is a composition formed by melting a pound of elemi with two pounds of prepared suet; then removing it from the fire, and immediately mixing in ten ounces of common turpentine, and two fluid-ounces of olive oil; then straining the mixture through a linen cloth. See **ELEMI**.

LINIMENTUM CAMPHORÆ, *Camphor liniment*, is prepared by dissolving half an ounce of camphor in two fluid-ounces of olive oil. This is a simple solution of camphor in oil, which readily dissolves it. The same solution also affords an useful method of giving camphor internally in a liquid form, by rubbing it in this state first with mucilage, and then adding any aqueous vehicle. One drachm of the oil contains, as thus prepared, fifteen grains of camphor. See **CAMPHOR**.

LINIMENTUM CAMPHORÆ Compositum, *Compound camphor liniment*, is prepared by mixing six fluid-ounces of solution of ammonia with a pint of spirit of lavender in a glass retort; then, by the heat of a slow fire, distilling a pint; and lastly in this distilled liquor dissolving two ounces of camphor. See **CAMPHOR**.

LINIMENTUM HYDRARGYRI, *Mercurial liniment*, consists of the following ingredients; *viz.* strong mercurial ointment and prepared lard, of each four ounces, an ounce of camphor, 15 minims (of which to make a fluidrachm) of rectified spirit, and four fluid-ounces of solution of ammonia. It is prepared by first powdering the camphor with the addition of the spirit, then rubbing it with the mercurial ointment and the lard, and, lastly, adding gradually the solution of ammonia, and mixing the whole together. This combination requires that the camphor should be powdered by the smallst possible quantity of spirit, and if the other substances be added in the manner above directed, it will form a mass of uniform consistence without separating; and it will be considerably thicker than the other liniments are. It is an useful combination for the dissolution of indolent swellings or collections of fluid; but if it be frequently or largely

applied, it will affect the mouth more rapidly than the mercurial ointment will do.

LINIMENTUM SAPONACEUM, *Linimentum saponis compositum*, or *compound soap-liniment*, a form of medicine prescribed in the London Pharmacopœia, and meant to supply the place of the ointment well known by the name of *epididymæ*. It is made thus: take spirit of rosemary a pint, hard Spanish soap three ounces, camphor one ounce; dissolve the camphor with the rosemary spirit, and then add the soap; and macerate in the heat of a fluid-bath until it be melted.

A liniment of this kind may be prepared by rubbing an ounce of camphor, with two ounces of Florence oil, in a mortar, till the camphor be dissolved. This anti-spasmodic liniment may be used in obstinate rheum, tismus, and in some other cases, accompanied with extreme pain and tension of the parts.

LINIMENTUM TEREBINTHINÆ, *Turpentine liniment*, is formed by adding half a pint of oil of turpentine to a pound of resin cerate previously melted, and stirring. This liniment is very commonly applied to burns; and its first introduction into practice for this purpose is owing to Mr. Kentish of Newcastle.

LINIMENTUM VOLATILE, P. L. 1745; *Linimentum ammoniac*, P. L. 1787; *Linimentum ammoniac carbonatis*, *liniment of carbonate of ammonia*, is formed by shaking together a fluid-ounce of solution of carbonate of ammonia with three fluid-ounces of olive-oil, until they unite. Or this liniment may be prepared by shaking together an ounce of Florence oil, and half an ounce of spirit of harts-horn. If the patient's skin is able to bear it, the liniment, made with equal parts of the spirit and oil, will be more efficacious. Sir John Pringle observes, that in the inflammatory quinsy, a piece of flannel moistened with the liniment and applied to the throat, to be renewed every four or five hours, is one of the most efficacious remedies; and that it seldom fails, after bleeding, either to lessen or carry off the complaint.

A liniment for burns may be made by shaking well together, in a wide-mouthed bottle, equal parts of Florence oil, or of fresh drawn linseed oil, and lime-water. This is found to be an exceeding proper application for recent scalds or burns. It may either be spread upon a cloth, or the parts affected may be anointed with it twice or thrice a day.

A liniment for the piles may be made by mixing two ounces of emollient ointment, and half an ounce of liquid laudanum, with the yolk of an egg, and working them well together.

LINING, in *Canal-Making*, signifies a thickness or coat of puddle, sometimes applied to the bottoms and sides of canals, to prevent them from leaking, as *qrst*, *Plate I. Canals*, *fig. 15*.

LINING of Hot-beds, in *Gardening*, is the art or practice of applying a proper layer of hot dung to the sides of the beds, to revive and keep up the declining heat of them. It is essentially necessary, in the culture of plants on dung hot-beds, in the early seasons in winter or spring, until May. As these hot-beds generally, in from three or four to five or six weeks, according to their substance, begin to decline in their degree of heat, they require of course a revival to continue them in regular heat; which, in dung hot-beds, can only be effected in this manner. It is applied to one or both sides, as there may be occasion, or as heat may be wanted.

Hence in this way, by the occasional repetition of two, three, or more linings, a hot-bed may be continued in a proper degree of heat several months, as exemplified in early cucumber and melon hot-beds; which, without the aid of occasional

occasional linings, would not retain sufficient heat to forward their respective plants, &c. to proper perfection.

The dung for this purpose should be of the best fresh horse stable kind, moist and full of a steamy lively heat, being prepared in the manner described under *Hot-Bed*, and in proper quantity to make the lining substantial, as 15 or 18 inches wide, and as high as the dung of the hot-bed; as, when too slender, they do not effect the intended purpose, especially in early beds, or when the heat is considerably decreased.

And in early hot-bed work, care should be taken, according to the extent of the bed or beds and season of the year, to allot and reserve a sufficiency of dung for linings: early beds in very cold weather will generally require more substantial and frequent linings than later made beds in the advanced spring months; and some hot-beds, for slight or temporary uses, just to raise plants for two or three weeks, will sometimes require but very little or no linings. Hot-beds made late, as in the beginning or any time in May, will need but very trifling linings, or some not at all, except in particular uses, as when plants are rather backward in growth, the weather cold, and the bed declined much in heat, when, probably, even in May, or beginning of June, a final moderate lining may become necessary.

It is necessary that the requisite linings should always be applied to the respective hot-beds in proper time, which may be ascertained by examining the state of heat; not letting them decline too considerably before they are applied, but to continue always a moderately lively heat, but never violent. Linings are sometimes applied by degrees, raising them only half-way at first; adding more in height in a few days, and thus proceeding till they are raised to the height of the hot-beds.

And in application of linings, it is generally necessary to line only one side at a time, commonly the back part of the bed first; and in a week or fortnight after, to line the front side, and both ends, if necessary; or in particular cases of the hot-bed having suddenly declined, or been permitted to decrease very considerably in heat before applying the lining, to line both sides moderately at once, about 12 or 15 inches in width, but only as high as the dung of the bed at first; being afterwards a little augmented by degrees, according as the dung of the lining settles.

The general requisite thickness or substance of the linings is from 12 to 15 or 18 inches width in dung, and as high as the dung of the bed, or sometimes a few inches higher; but for early beds of cucumbers, melons, or other plants of long continuance in hot-beds, they should generally be laid from 15 to 18 inches in width at bottom, as conceived necessary, narrowing the width gradually upwards to 8, 10, or 12 inches at top, which may be raised at once to the full height of the dung of the bed, or a few inches higher up the side of the frame, to allow for settling: but with a strong lining, great caution should be used in raising it much above the dung of the hot-bed, especially when made of very strong, hot, steamy dung, for fear either of its throwing in a too strong heat above to burn the internal earth of the bed, or imparting a copious rank steam to penetrate within the frame, which would steam-scald the tender plants which may be contained therein.

As soon as the linings are raised to the intended height, it is proper in general to lay a stratum of earth at top two inches thick, close up to the bed or bottom part of the frame, sloping a little outward to throw off the fallow wet of rain, snow, &c.; which top-covering of earth is essential, both to keep the heat of the linings from escaping too considerably above, in order that it may be directed more ef-

fectually to its intended purpose of imparting its whole principal heat internally to the revival of that of the bed, and prevent the strong steam arising immediately from the rank dung from entering the frame at bottom, or through any small crevice, or at top, when the lights are occasionally raised for the admission of fresh air; as the rank dung steam thus produced, without being moderated and corrected by first passing through a stratum of earth, if it should enter within the frame considerably, would prove very pernicious to most plants, and be the total destruction of some particular kinds.

And constant care must be taken, that as the heat of the linings declines to any extent, they must, as just noticed, be renewed by a supply of fresh hot dung. This may sometimes be effected by turning over, and shaking up the same dung mixedly together, directly forming it again into a lining: or some of the best or least decayed or exhausted parts of the old lining may only be used, mixing it up properly with a good supply of new dung, applying it immediately in a proper substantial lining as before. In either of these ways, fresh air is entangled, by which a new fermentation and heat is brought on. However, where the dung of the linings is greatly exhausted, fresh dung should mostly be used in the renewal of the heat.

And linings of hot dung are sometimes used substantially, in working some sorts of forcing-frames, in raising early flowers and fruits, by applying the dung against the back of the frame, two or three feet in width at bottom, narrowing gradually to a foot and a half, or less, at the top, raising the whole according to the height of the frame, from four or five to six or seven feet; which heating considerably against the whole back of the frame, communicates the heat internally, by which the different plants are forwarded to early production; supporting the internal heat by renewing the linings, as already directed. See *Forcing-Frames*, and *Garden-FRAME*.

Linings of dung are also sometimes used in supporting the heat of nursery hot-beds for young pine-apple plants, and some other exotics of the hot-house or stove, both in dung and tan-bark hot-beds, under proper frames and glasses; as well as those wintered in these detached hot-beds distinct from the hot-house, &c. in which a constant regular heat, almost equal to that of the stove, must be supported; so that, when the natural heat of the bed is on the decline, a strong lining of hot dung must be applied, half a yard or two feet wide below, narrowing moderately upward, and continued on both sides occasionally: and as the heat of them subsides, it must be immediately renewed by a supply of fresh dung, either worked up with the best of that of the declined dung; or, if this be too much decayed, wholly of new: and thus the hot-beds maintained in a proper degree of heat from the autumn until the spring season, when they become unnecessary.

And the decayed dung of the different linings, when done with, becomes excellent manure for the kitchen-garden departments.

LINING, in *Map-Making*, denotes the marking of the length, breadth, or depth of any thing, according to design, by a cord, rubbed with white or red chalk, fastened at the extremities, and forcibly pulled up in the middle, or towards one end, then let fall perpendicularly, if meant to be straight, or thrown sideways to form a curve. Accuracy in the later performance requires practice.

LININGS, in *Sail-Making*, signify the canvas sewed on the backs and middle of a sail, to strengthen it.

LINITAN, in *Geography*, a small island in the East

India.

Indian sea, five miles north from the island of Serangan, to which it belongs. S. lat. 5° 36'. E. long. 125° 21'.

LIN-KIANG, a city of China, of the first class, in the province of Kiang-ni, situated on the banks of the river Yu-ho. Its soil is good, and the climate is healthful; but it is so much deserted that the Chinese say, "one hog would be sufficient to maintain the whole city two days." Four cities of the third class belong to its district. One of its villages is the general mart for all the drugs sold in the empire; and this circumstance gives it some degree of celebrity. N. lat. 27° 58'. E. long. 115°.

LINKLO, in *Botany*, a kind of water-plant among the Chinese, the fruit of which is of a triangular pyramidal form, prominent every way, with a green thick rind, that grows reddish towards the apex, and, when the fruit is dried, grows black. The internal substance is exceeding white, its taste like that of the chestnut, three or four of which it equals in bulk. The plant is found in standing waters, and has very slender leaves, that spread themselves over a large extent on the surface of the water, and the fruit lies concealed under water in great numbers.

LINKÖPING, in *Geography*, a small and neat town of Sweden, in East Gotland, situated on the river Stöng, near lake Roxen; containing an episcopal palace, a cathedral, and the house which is the residence of the governor of East Gotland. It has three churches and a public seminary; 96 miles S.W. from Stockholm. N. lat. 58° 26'. E. long. 15° 18'.

LINKNESS, a cape of Scotland, on the N.W. coast of the island of Stronfa; 1½ mile S.W. of Huipness. N. lat. 59° 4'. E. long. 0° 26'.

LINLEY, JOHN, in *Biography*, an eminent music professor and organist, long resident at Bath, where he had served an apprenticeship under Chilcot, the organist of that city. Linley loved music, was a studious man, equally versed in the theory and practice of his art. Having a large family of children, in whom he found the seeds of genius had been planted by nature, and the gift of voice, which, in order to cultivate, he pointed his studies to singing, and became the best singing master of his time, if we may judge by the specimens of his success in his own family. He was not only a masterly player on the organ and harpsichord, but a good composer, as his elegies and several compositions for Drury-lane theatre evinced. His son, Thomas, who was placed under Nardini at Florence, the celebrated disciple of Tartini, was a fine performer on the violin, with a talent for composition; which, if he had lived to develope, would have given longevity to his fame. Being at Grimthorpe, in Lincolnshire, at the feat of the duke of Ancaster, where he often amused himself in rowing, fishing, and sailing in a boat on a piece of water, in a squall of wind, or by some accident, the boat was overset, and this amiable and promising youth was drowned at an early age, to the great affliction of his family and friends, particularly his matchless sister, Mrs. Sheridan, whom this calamity rendered miserable for a long time; during which, her affection and grief were distilled in verses of the most sweet and affecting kind on the sorrowful event. The beauty, talents, and mental endowments of this "Sancta Cecilia rediviva," will be remembered to the last hour of all who heard, or even saw and conversed with her. The tone of her voice and expressive manner of singing were as enchanting as her countenance and conversation. In her singing, with a melodious toned voice, a perfect shake and intonation, she was possessed of the double power of delighting an audience equally in pathetic strains, and songs of brilliant execution, which is allowed to very few singers. When she had heard the Agujuri, and the Danzi, afterwards Madame

Le Brun, she astonished all hearers by performing their bravura airs, extending the natural compass of her voice a fourth above the highest note of the harpsichord, before additional keys were in fashion. Mrs. Sheridan died at Bristol in 1792.

Mrs. Tickel, her sister, was but little inferior to her in beauty and talents, and Mr. Linley's other daughters continued to excite the admiration of all who knew them, in a manner worthy of the family from which they sprung.

Mr. Linley, the father of this nest of nightingales, from being assistant manager of Drury-lane theatre, lived to become joint patentee, and, for some time, sole acting manager; in which capacity, he gave more satisfaction, and escaped censure, public and private, by his probity and steady conduct, more than is often allowed to the governor of such a numerous and forward family. This worthy and ingenious man died November 1795.

LINLITHGOW, in *Geography*, a royal borough and county town of Linlithgowshire, or West-Lothian, Scotland. It is situated on the road between Edinburgh and Stirling, at the distance of 16 miles from the metropolis. This town has claims to considerable celebrity, both on account of the connection of its history with some of the most important transactions of the kingdom, and of the noble remains of former magnificence with which it is adorned. As the reader will find mentioned in the following article, the name of this place is purely of British origin, and peculiarly descriptive in its application. During the reign of David I., Linlithgow formed a part of the royal demesnes, and had a castle and a grange, at which that monarch and his successors frequently resided. When Alexander III. died, an event which happened before this town obtained its charter, it was governed by two bailies, as we learn from a writ addressed to them by Edward I., dated the 28th of August 1296, requiring them to make payment of some arrears, due to the king of Norway, by the firm of the town. In the year 1298, the same monarch encamped his army on the height immediately to the east of Linlithgow on the night before the battle of Falkirk, in which the celebrated patriot, sir William Wallace, was defeated through the treachery of Cumming. This town was formerly a place of very considerable commerce, opulence, and splendour, but all these advantages began gradually to decay, after the union of the two crowns, in the person of James VI. It once had an exclusive right of trade from the water of Craigh to the mouth of the Avon. Blackness castle was then assigned to it as a port, and at this place many warehouses were erected, some of which are still standing. A custom-house was likewise situated here, till removed in the last century to Borrowstowness, through the interest of the Hamilton family.

The period at which Linlithgow was first constituted a royal borough by charter is uncertain, but it has doubtless existed in that capacity from a very early period. In the reign of David I. it is declared by act of parliament one of the principal burghs of the kingdom. Since that time it has received several charters, all of which were confirmed in 1540 by a writ of *Novodamus* from James V. The government of this town at present is vested in a provost, four bailies, a dean of guild, twelve merchant counsellors, and the deacons of the eight incorporated trades. The principal manufacture now carried on is that of leather: shoemaking is a thriving business. The woollen trade is also considerable, and about a mile from the town there has lately been established a very extensive bleach field, which gives employment to nearly 300 persons.

The present condition of Linlithgow, with respect to exterior view, is much inferior to what it formerly was.

From the antiquity of many of the houses, the whole exhibits, at first sight, a ruinous and decayed appearance. There are, however, a number of good buildings still to be found. It consists chiefly of one street, extending nearly a mile in length, from east to west. This is intersected by a variety of smaller streets or lanes. The ruins of the palace stand on a rising ground, immediately overlooking the town. They are evidently the remains of a once magnificent and superb mansion. The situation of these ruins is extremely fine, and such as, in ancient times, would render it well calculated for defence. The eminence on which it is situated runs a considerable way in an extensive lake, which conduces greatly to the ornament both of the town and cattle. The first foundation upon this spot is said to have been at least coeval with the period of the Gadeni. There seems reason to believe it was afterwards the site of a Roman station. Fordun says that Edward I. erected a *pila* here in 1300. This, however, is doubtful, as it is unquestionably true that there was a royal residence here before that period, which cannot be supposed to have been unfortified in those times. It is very probable that this monarch only repaired it for his reception in 1301, previous to passing his Christmas in it, which he did that year. During the civil dissensions between Bruce and Baliol, this castle was taken by stratagem, through the means of one Binnoch or Binny, who secretly favoured the cause of Bruce. Binnoch, being accustomed to supply the fortrefs with hay, was well known, and had free access at all times. Under these circumstances he proposed to Bruce to conceal some armed men in his cart, which should be apparently loaded with hay. These being admitted, secured the guards, and made themselves masters of the place. For this service Binnoch was rewarded with some lands in the neighbourhood. In the reign of Edward III. this castle was again seized by the English. In 1424 it was destroyed by fire, as well as the greater part of the town. The name of the person by whom the former was rebuilt is unknown. It became a fixed royal residence soon after the accession of the house of Stewart to the throne of Scotland; and was several times assigned as a jointure-house to the queens of that kingdom. In October 1488, this palace was delivered to the rule of lord Hailes and Alexander Home, two of the principal leaders of the rebellion against James III., one of the mildest monarchs that ever graced a throne, whose melancholy fate every feeling heart must pity and bewail. In 1517 it was seized by Stirling and his followers, who had attempted to assassinate Melburne; but was soon afterwards retaken by assault by De la Bastie, the regent's lieutenant, when the assassins were fortunately secured. James V. resided for the most part in this palace, during his minority. The battle of Linlithgow was fought on the 4th September 1526, with the view of rescuing that prince from the domination of the earl of Angus. In this action, the earl of Lennox, the friend of James, was slain, after quarter given, by sir James Hamilton. To the last-mentioned monarch and to James VI. this palace was indebted for much of its magnificence and grandeur. Over the inside of the grand gate there formerly stood a statue of pope Julius II. with the triple crown, who sent a consecrated sword and helmet to James V. This piece of sculpture, after escaping for more than a century the fury of the reformers, ultimately fell a sacrifice to the pious zeal of a blacksmith. The whole palace is constructed of hewn stone, and covers about an acre of ground. It has in the centre a handsome square, one side of which is more modern than the others, having been built by James VI. In one portion of this building is a very superb room, 90 feet long, 30 feet 6 inches wide, and 33 high. At one end is a gallery with three arches,

probably intended for musicians. The parliament-chamber, in which the unfortunate queen Mary was born on the 8th December 1542, has likewise been an elegant apartment. The whole was kept in good repair till the year 1746, when being used as a barrack, a great part of it was accidentally burnt by the king's troops. Since that period it has been suffered to fall into ruins. The church of Linlithgow, which is appended to the palace, is a very fine building. Some of the windows are particularly beautiful. In this edifice the aisle is still shewn, in which James IV. is said to have seen an apparition, warning him of the impending fate of the battle of Flowden, in which that monarch and the flower of his nobility were slain. As there is no doubt but a person in an unusual habit did accost that prince, when attending the evening service in this aisle, it is supposed to have been a stratagem of the queen's, to dissuade him from his intended enterprize against England, which a credulous and superstitious age converted into a supernatural and prophetic admonition. The church is adorned with a handsome spire, surmounted with an imperial crown. A number of statues formerly decorated the outside, but were all destroyed by the reformers, except that of the patron of the church, the archangel St. Michael. The house from which Hamilton shot the regent Murray, in the reign of queen Mary, is still standing. This murder is one of the most deliberate recorded in the annals of history. The town-house, erected in 1668, is a commodious and elegant structure. In front, but at some distance from it, there was formerly an antique cross, ornamented with grotesque figures, and having eight spouts at different elevations, from which the water was poured. This having become much decayed, a new one, of similar construction, has lately been erected. Linlithgow anciently possessed a variety of religious establishments. In 1290 the inhabitants founded a convent of Carmelites, or White friars, on an eminence south of the town, still called Friars' Brae. St. Magdalen's on the east, situated at the foot of Pilgrim's hill, was formerly a *hospitium*, or place of entertainment for strangers. The Dominican or Black friars had likewise a monastery here. All these buildings were demolished by the earl of Argyle, lord James Stewart, and John Knox, when they visited Linlithgow in their progress of reform. Linlithgow rendered itself conspicuous by the part its inhabitants took in the grand rebellion. It had its full share in the miseries of that distracted period. The solemn league and covenant was publicly burned here, on the anniversary of the restoration in 1662, by the inhabitants themselves, without any authority from government. This town ranks as the sixth among the royal boroughs of Scotland. Since the union, it has been associated with Lanark, Selkirk, and Peebles, in the privilege of sending one representative to parliament. Winzet, the famous polemical antagonist of John Knox, was master of the Linlithgow school, when chosen by the Catholic clergy to defend their principles and rights.

The parish of Linlithgow is about five miles in length, and three in breadth: it is in general well cultivated and enclosed. Coal is abundant in different parts of it, but no pits are at present wrought. There is likewise plenty of lime-stone, but free-stone is scarce. Copper-ore has been found in one spot; and in the southern extremity there is a silver mine, which is said to have been formerly wrought to great advantage. The population of the whole parish, according to the parliamentary returns of 1801, amounted to 3594 persons; the houses were estimated at 746. Sinclair's Statistical Account of Scotland.

LINLITHGOWSHIRE, or WEST Lothian, a county on the southern shore of the Frith of Forth in Scotland.

LINLITHGOWSHIRE.

land. It is separated from Edinburghshire on the east and south-east by the rivulets Priece and Amow, except at Mid-cadder, where the latter county intrudes somewhat more than a mile into Linlithgowshire. On the west it is divided from Stirlingshire, first by the Linn-burn, and after its junction with the Avon, by that river, till it discharges itself into the Forth. A part of Lanarkshire forms the boundary on the south-west, while the waters of the Forth wash its coast for the extent of fourteen miles on the north. The form of this county is that of an irregular triangle. Its medium breadth from north to south is little more than seven miles, and its medium length about sixteen. It contains nearly 112 square miles, or 57,008 Scottish acres. The parishes amount to 13 in number, comprising, according to the parliamentary returns of 1800, a population of 17,844 persons.

The aspect of this county, except towards the south, where it consists chiefly of moor-moats and morafs, is that of a level and well cultivated district, diversified by a variety of small hills: these are most numerous in the middle and western parts of the county. Beginning at Bowden, the more remarkable of them form a range which runs through the centre of the county in an oblique direction from north-west to south-east. In the northern district they are less elevated than towards the middle and western parts, and are more variously distributed. In general they are both useful and ornamental, nearly the whole of them affording abundant pasture; many of them being clothed with woods; and not a few of them containing valuable minerals.

Soil and Climate.—This county exhibits a great diversity of soils, as well as a variety of climate. Almost every kind of clayey soil is to be found in different parts of it. About 7000 acres are composed of light gravel and sand, and nearly the same extent of that species which is usually called loam. The high rocky land extends to about 10,000 acres, and the moor to somewhat better than 1000. Such parts of this county as border on the Forth, have a temperate and an excellent climate. The upper or south-western part, however, is not so much favoured. Its elevated situation with the proximity of the moors and moorlands, either in this county or the neighbouring one of Lanark, render it bleak and damp during the greater part of the year.

The lands of this county are possessed by between thirty and forty landholders whose estates vary from 2000 to 60000 *per ann. val.* besides a few of inferior rental. About a third part of the county consists of wood and pasture lands, or is laid down with artificial grasses. The cause of this great proportion of pasture grass seems to be the vicinity of Edinburgh. The agriculture of this county is similar to that of the other Lothians. The upper portions are the poorest, but even in the highest moors of that district, art and industry are making rapid changes and improvements. The grub-worm is perhaps more destructive in this than in most other counties. This insect generally begins its depredations in May or June, especially if the lands have been formerly in grass, or over-run with moss, and the crops are blighted which is apt to be the case, from the dry east winds which prevail during these months. Not above one-sixth of the whole county remains uncultivated. Great attention is paid to the forming of plantations, particularly in the neighbourhood of gentlemen's seats, which tend in no small degree to enliven the scenery of this cultivated district. The shores of the Forth are peculiarly ornamented both by nature and art. Bowden park, the seat of the earl of Roseberry, is laid out with plantations, formed in the very best taste, and in a manner well calculated to shelter the soil, and exhibit the aspect of the country around to great advantage. On

the coast, Linlithgowshire rises suddenly into a ridge adorned by culture and well wooded. From hence westward by the ancient seat of the Dundas family, and by Hopetoun-house, a series of views are to be met with not inferior to any in the kingdom. The scenery in the immediate neighbourhood of Queensferry is peculiarly fine, the Forth here forming a narrow strait, which expands suddenly on both sides into an extensive bay, with richly ornamented banks. At various points of the coast the views are different, the water assuming the appearance of a lake, a noble river or broad sea, according to the situation from which it is seen. In one spot, a little distance from the shore, stands Hopetoun-house, one of the most superb and magnificent seats in this kingdom. It is situated on a noble and extensive lawn, stretching to the distance of more than a mile from the front of the house, and forming a sort of terrace along the banks of the Forth, which winds round it, and presents the view of a wide extensive lake, interspersed with islands, and enlivened by a variety of shipping. Behind the house the ground is more various, breaking into hills, vallies, and promontories, which shoot into the Forth. To a considerable distance the grounds seem well wooded and enclosed; the house itself is flanked with a noble plantation, which serves to shelter it from the northern blasts. At the extremities of this vast and magnificent scenery a variety of mountains arise of different forms and at different distances. In short, every thing the eye can contemplate in the whole scene, or its appendages, is great and noble. The situation of the house, and its architecture, are also equally objects of admiration. It was planned and begun by the celebrated architect Sir William Bruce, and finished by Mr. Adams. Some of the apartments are grand and spacious, but they are in general of moderate size, which is perhaps the only defect of its contrivance. It abounds with paintings.

With the exception of free-stone and coals, there are no minerals of any importance in the county. In the Balligat-hills there was formerly a valuable lead mine, but being now fought in vain is supposed to be exhausted. A free-stone quarry, in the neighbourhood of Queensferry, is one of the finest in the kingdom. More than three acres have been already excavated. This stone is exported in great quantity, both as materials for building, and in the shape of grinding-stones. Coal abounds in different parts of the county; but is chiefly wrought in the neighbourhood of Borrowstoness. Here is one of the most extraordinary coal mines in the world: it extends under the Forth half way across. Formerly there was a building, or moat, about half a mile from the shore, where there was an entry down into the pit formed under the sea. This building being in the shape of a quay, vessels were brought along side of it, and loaded with the coals raised from the pit and deposited here. This mine was extremely profitable, but at last an unexampled high tide overwhelmed the whole, before the colliers could effect their escape. This did not discourage the daring adventurers. A new mine was opened, and continues to be wrought at this day to a great extent. For the purpose of rendering the coal in the upper parts of this county more extensively useful, it has been proposed to cut a canal from Glasgow to Edinburgh, which might likewise bring to the eastward, at a cheap rate, a portion of the treasures contained in the hills of Lanarkshire. To these useful productions of the mineral description in this county, may be added iron-stone, whin-stone, grey granite, and shell marl. On the south side of Dundas-hill is a basaltic rock, 250 yards in length, and 60 or 70 feet high. The masses are in an irregular state, formed like pillars, separated by channels; but not a few of them exhibit regular

lar and well defined prisms. The stone of which these are composed is of a light bluish colour.

The royal boroughs in this county are Linlithgow and Queensferry. The former is the shire town, and situated in the interior of the county. The latter stands on the coast of the Forth, about nine miles west from Edinburgh. It was formerly of more importance than at present; it being now totally destitute of trade. A particular account of these boroughs will be found under their respective names.

Borrowstowness, or Bo-ness, is the principal sea-port town in this county. It is a borough of barony, governed by a bailiff appointed by the duke of Hamilton. The houses in this place are low and crowded, and much injured in appearance, by the smoke of the numerous salt pans with which it abounds. The produce of these pans, and of the coal-works in the neighbourhood, are the chief articles of export from this town. The harbour is considered very safe. About thirty sail of shipping belong to persons resident on the spot. Many others frequent this harbour in the course of trade. The imports are usually tallow, hemp, timber, flax, and flax-seed. The herring-fishery is carried on here, but, being hazardous and precarious, scarcely deserves notice in mentioning the commerce of this port. Kineel house, belonging to the duke of Hamilton, is beautifully situated on the shore of the Forth, not far from the town. The village of Bathgate stands on the southern declivity of the hills which bear its name, and form a part of the range already mentioned, as running through the centre of the county. Here, as well as in the village of Whitburn, situated on the most southern road between Edinburgh and Glasgow, a number of weavers are employed by the Glasgow manufacturers. At present neither of these places is of much importance: but is the event of the proposed canal, formerly noticed, being carried into effect, it is not improbable they would soon rise into considerable distinction. Besides these, there are few other villages in this county which do not, however, require particular notice.

Among the antiquities of this county is the termination of the celebrated Roman barrier, or wall of Antoninus. It enters Linlithgowshire near the village of Inner Avon, and proceeds by Kineel house to the village of Carriden, behind the church of which, it is probable, the last or nineteenth fort, counting from the Clyde, was stationed, though no remains of the work can now be discovered beyond the inclosures of Grange. Two miles east from Carriden, and one and three quarters west from Abercorn, is Blacknefs castle, which, from its situation with regard to the wall, seems not improbably to have been the Roman port on the Forth. In Abercorn parish, on a point north-east from the church, Abercorn castle was formerly situated. It was one of the strong holds of the Douglasses, and was taken by storm, after a long siege, by James II. during his contest with that family. After this it was never repaired, and Buchanan mentions it as a ruin in his time. The most ancient monastery in Scotland was situated here, as we learn from the venerable Bede, after whose time it is not mentioned in history. In Torphechen parish was a house for the knights of St. John; it was founded by king David I. This preceptory was a place of refuge, or sanctuary. In the church-yard is a stone with a St. John's cross on it, and four similar ones at the distance of a mile each. This parish is also distinguished by four great stones, situated about a mile east of the village, which are said to have been a Druidical temple. In Kirkliston parish is another remarkable stone, known to the inhabitants by the name of the *Cat Stone*. It is four feet and a half high, and eleven feet

VOL. XXI.

and a half in circumference. The form is that of an irregular prism. On one side is the following inscription, rudely, but deeply, cut, the explanation of which has puzzled many antiquaries. "IN OC. TUMVLO JACI UETTA DUCTA." The church of Dalmeny may likewise be ranked among the antiquities of this county. Concerning the date of its erection nothing is known. Its architecture is of that middle fort which has received the appellation of Saxon. It is a small building, apparently with Grecian windows, but upon investigation, the shafts are found to be disproportionate. The eastern portion of this church is vaulted with semicircular arches, having mouldings chiefly in the form of stars and other decorations. Sinclair's Statistical Account of Scotland. Chalmer's Caledonia.

LINNÆA, in *Botany*, so called in honour of the great Swedish naturalist, (see LINNÆUS,) appears by the journal of his Tour to Lapland to have been chosen by himself to commemorate his own name, when he gathered it at Lykfele, May 29, 1732. Former botanists had called this elegant and singular little plant *Campanula serpyllifolia*; but Linnæus, prosecuting the study of vegetables on the only certain principles, the structure of their parts of fructification, soon found this to constitute a new genus. He reserved the idea in his own breast, till his discoveries and publications had entitled him to botanical commemoration, and his friend Gronovius, in due time, undertook to make this genus known to the world. It was published by Linnæus himself in the *Genera Plantarum*, ed. 1, in 1737, and the same year in the *Flora Lapponica*, with a plate, being moreover mentioned in the *Critica Botanica*, p. 80, as "a humble, despised, and neglected Lapland plant, flowering at an early age," like the person whose name it bears. Linn. Gen. 319. Schreb. 418. Willd. Sp. Pl. v. 3. 340. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 606. Juss. 211. Lamarck Illustr. t. 536. — Class and order, *Didynamia Angiospermia*. Nat. Ord. *Aggregate*. Linn. *Caprifolia*, Juss.

Gen. Ch. Cal. Perianth double; that of the fruit inferior, of two or four leaves; the outermost of which are opposite and minate; the others elliptical, concave, erect, hispid, closed around the germen, permanent: that of the flower (the proper one) superior, of one leaf, in five erect, narrow, acute, equal, deep segments. Cor. of one petal, above twice as long as its perianth, bell-shaped, its border in five rather deep, obtuse, nearly equal divisions. Stam. Filaments four, awl-shaped, inserted into the bottom of the corolla, two of them much the smallest; anthers compressed, versatile. Pist. Germen roundish, interior; style thread-shaped, straight, the length of the corolla, inclining; stigma globose. Peric. Berry dry, ovate, of three cells, clothed with the hispid glutinous perianth of the fruit, deciduous. Seeds roundish, two in each cell.

Eff. Ch. Calyx double; that of the fruit of two or four leaves; that of the flower superior, in five deep divisions. Corolla bell-shaped. Berry dry, of three cells.

Obs. The two outer or smaller leaves of the inferior calyx are often wanting. When present they are like the inner ones in shape, though smaller in size, and stand like them close to the germen, being totally distinct from the bractæ, which are a little remote from them, lanceolate and acute.

1. *L. Lorealis*. Linn Sp. Pl. 880. Fl. Suec. 210. t. 1. Fl. Lapp. ed. 2. 214. t. 12. f. 4. Engl. Bot. t. 433. Fl. Dan. t. 3. (*Campanula serpyllifolia*; Bauh. Prodr. 35.)—Native of dry stony mossy ancient fir woods, in Sweden, Siberia, Russia, Switzerland, Scotland, and North America, flowering in May and June. Linnæus describes it in his Lapland Tour, v. 1. 20, as clothing masses of stones,

P

being

being interwoven with ivy, in a picturesque manner. It was first discovered in Britain, June 2d, 1795, by the late professor James Beattie of Aberdeen, in an old fir wood at Mearns in that county.

The *root* is fibrous and perennial. *Stems* trailing, creeping, perennial, woody, round, leafy, somewhat hairy, often reddish, a little branched, very long and slender. *Leaves* evergreen, opposite, stalked, roundish or ovate, veiny, crenate in the fore-part, paler beneath, bearing a few scattered hairs on the upper side. Flowering *branches* erect, three or four inches high, with a pair or two of leaves near the bottom, naked above, terminating in two equal flower-stalks, with a pair of small leaves at their origin, and each bearing one drooping *flower*, accompanied by two small, lanceolate, slightly remote, opposite *bracts*, which, like the stalks, calyx and germen, are clothed with glandular viscid hairs. The *flowers* are of a delicate pink, especially within, being pale white or yellowish externally. They are said in the *Flora Suecica* to be very fragrant at night, smelling like Meadow-sweet. An infusion of the leaves, with milk, is esteemed a specific, among the Swedes, in rheumatic and febrile disorders. The inhabitants of Weß Bothnia cure painful complaints in the feet of their sheep, with a cataplasm or fomentation made of this herb. The smoke of it when burnt is thought by the Norwegians beneficial in the scarlet fever, and its decoction in the itch.

This is the only known species of *Linnaea*. The right honourable sir Joseph Banks is possessed of a drawing, made by an artist who was employed many years ago to delineate plants in the East Indies, which represents a plant answering to the same generic characters, but of which no specimens having ever been seen, the drawing is supposed to be a forgery. The younger Linnaeus, when in England, was much interested by the sight of it, but endeavoured in vain to ascertain its truth.

LINNEAN System of Botany. See BOTANY, FLOWERS, and SEXUAL System.

LINNÆUS, CHARLES, afterwards *VON LINNÉ*, in *Bio-graphy*, the most eminent of modern naturalists, whose labours and abilities rendered his favourite science of Botany first more phil. sophical, and then more popular, than it had ever been in any other age, was born at Råshult, in the province of Småland, in Sweden, May 13th, old style, 1707. His father Nicholas Linnaeus was assistant minister of the parish of Stenbrohult, to which the hamlet of Råshult belongs, and became in process of time its pastor or rector; having married Christina Broderfson, the daughter of his predecessor. The subject of our memoir was their first-born child. The family of Linnaeus had been peasants, but some of them, early in the 17th century, had followed literary pursuits. In the beginning of that century regular and hereditary surnames were first adopted in Sweden, on which occasion literary men often chose one of Latin or Greek derivation and structure, retaining the termination proper to the learned languages, as Melander, even when the name itself was not taken from thence, as Retzius. A remarkable Linden-tree, *Tilia europæa*, growing near the place of their residence, is reported to have given origin to the names of Lindelius and Tiliander, in some branches of this family; but the above-mentioned Nicholas is said to have first taken that of Linnaeus, by which his son became so extensively known. Of the taste which laid the foundation of his happiness as well as his celebrity, this worthy father was the primary cause. Residing in a delightful spot, on the banks of a fine lake, surrounded by hills and valleys, woods and cultivated ground, his garden and his fields yielded him both amusement and profit, and his infant son

imbibed, under his auspices, that pure and ardent love of nature for its own sake, with that habitual exercise of the mind in observation and activity, which ever after marked his character, and which were enhanced by a rectitude of principle, an elevation of devotional taste, a warmth of feeling, and an amiableness of manners, rarely united in those who so transcendently excel in any branch of philosophy or science, because the cultivation of the heart does by no means so constantly as it ought keep pace with that of the understanding. The maternal uncle of Nicholas Linnaeus, Sveno Tiliander, who had educated him with his own children, was also fond of plants and of gardening, so that these tastes were in some measure hereditary. The young Charles, as he tells us himself, was no sooner out of his cradle, than he almost lived in his father's garden. He was scarcely four years old when he heard his father descant, to a rural party, on the distinctions and qualities of some particular plants, culled from the flowery turf on which they were seated, and this first botanical lecture was ever after remembered as an epocha in his scientific life. He never ceased to enquire of his father concerning the names and properties of all the productions of the garden and the fields, that he could possibly procure; nor did the economy of insects, even at this early period, escape his attention. His youthful inaptitude for retaining the names of natural objects, sometimes tired and displeased his instructor, whose wholesome authority in time corrected this defect, and perhaps early prevented his falling into the error of those desultory speculators of nature, who have agreed to despise that methodical and didactic precision of ideas, which, for want of early discipline, they could never attain. The memory of Linnaeus, indeed, like his powers of perception, was naturally good, and his sight was always remarkably acute. The vivacity and brilliant expression of his eyes are said to have lasted through life, and indeed are displayed in most of his portraits.

These flowery studies however were obliged to give way, in some measure, to less agreeable occupations, and unhappily the private tutor proved a man of less winning manners than the beloved parent. Thus at seven years of age grammar had but an unequal contest with botany in the mind of the young student. Nor was he much more fortunate when removed in 1717 to the grammar-school of Wexio, the master of which, as his disgusted pupil relates, "preferred stripes and punishments to admonitions and encouragements." Such a system was near extinguishing all the talents it was intended to cultivate, and when the youth was committed, two years afterwards, to the care of a more judicious and amiable private tutor than before, the horrors of the rod seem still to have predominated over his taste for learning. In 1722 he proved competent, nevertheless, to be admitted to a higher form in the school, and his drier studies were now allowed to be intermixed and sweetened with the recreations of botany. In 1724, being 17 years of age, he was removed to the superior seminary, or *Gymnasium*, and his destination was fixed for the church. But the original inclinations of his mind, and its early prejudices, here grew but the more apparent. He had no taste for Greek or Hebrew, ethics, metaphysics or theology; but he devoted himself with success to mathematics, natural philosophy, and a scientific pursuit of his darling botany. The *Chloris Gothica* of Bromelius, and *Hortus Upsalensis* of Rudbeck, which made a part of his little library, were calculated rather to fire than to satisfy his curiosity; while his Palmberg and Tillands might make him sensible how much more than they had accomplished still remained to be done. His own copies of these books, used with the utmost care and neatness, are

now before us. His literary reputation however made so little progress, that, when his father paid a visit to Wexio, in 1726, his tutors, like the sapient instructors of Newton at Cambridge, gave him up as a hopeless dunce. They advised that he should be put apprentice to a shoemaker, tailor, or some other handicraft trade, rather than be forced to pursue an object, for which he was evidently unfit. Fortunately, the disappointed parent met with a better counsellor in Dr. Rothmann, the lecturer on natural philosophy, who encouraged him to hope much from the inclination of his son to natural knowledge and practical observation, and recommended that he should be directed to the study of medicine. This good advice was supported with the gratuitous offer of taking the young man into his own house, for the year during which he was still to remain at the *Gymnasium*, which was gladly accepted. The worthy preceptor gave his pupil a private course of instruction in physiology on the Boerhaavian principles, and was rewarded by the success of his endeavours. He first suggested to Linnæus the true principles upon which botany ought to be studied, founded on the parts of fructification, and put the system of Tournefort into his hands, in the knowledge of which he made a rapid progress. Its very imperfections proved useful, in prompting him to attempt something more complete hereafter.

In 1727 Linnæus was matriculated at the university of Lund, having, on the 19th of August, undergone with credit the examination of the Dean, and even of the Professor of Eloquence, Papke. He devoted himself to the study of medicine, lodging at the house of a physician, Dr. Stobæus, whose library and museum of natural history, afforded the greatest delight and assistance to his ardent mind, and the study of which often robbed him of several hours of his natural repose. In the same house was a German student named Koules, eager like himself for instruction, and their friendship was mutually beneficial. Dr. Stobæus being infirm in health and spirits, Linnæus was allowed to relieve him occasionally from the labours of his profession, and soon became a great favourite. While botanizing in the country, in the spring of 1728, our young naturalist met with that accident, whatever it was, which he always attributed to the sting or bite of his supposed *Furia infernalis*, an animal whose existence has been doubted by many persons, and by some positively denied. We need not here repeat what is said under the article *FURIA*. His pupil Solander has recorded several cases of this accident or disease, and describes the animal as if he had seen it, in the *Nova Acta Upsalienfis*, v. 1. 55. In the ensuing summer Linnæus passed the vacation under his paternal roof. Here he met with his former patron Rothmann, by whose advice he was induced to quit Lund for Upsal, as a superior school of medicine and botany. But the slender support which his father could afford him, a capital of about \$7 sterling, being totally inadequate, he was, in this new situation, reduced to the greatest necessity. Private pupils were not to be procured by a poor unknown student. He was obliged to trust for chance to a meal; and when he relates that he had no way of mending his shoes but by folded paper, seems to have felt the want even of the cobbler's education which had been recommended to him. He had offended his old friend Stobæus by quitting Lund, and though he had brought with him a splendid Latin testimonial, from the Rector of that university, in which he was called *Pellissimus ornatusque dominus*, and was declared "to have conducted himself with no less diligence than correctness, so as to gain the affection of all who knew him," he seems to have obtained nothing more than a royal scholarship, which was conferred

upon him on the 16th of December, but of the value of which we are not informed. It appears however by the above account to have been totally insufficient for his maintenance. He nevertheless did not relax in his studies; but attended the lectures of the younger Rudbeck, then Professor at Upsal, as well as the medical ones of Professor Reberg; and made critical manuscript remarks upon all that he saw and heard.

In the autumn of 1729 his botanical taste and application raised up for him a new and very estimable patron, in the learned Dr. Olaus Celsius, Professor of Divinity, who met with him by chance in that academical garden, the fame of which he was destined hereafter to immortalize. This gentleman had then been intent, for above 30 years, upon the illustration of the plants mentioned in the Holy Scriptures, on which he published a very celebrated work in 1745, having travelled to the East on purpose to render it more perfect. He soon discovered the merit of Linnæus, took him under his protection, and allowed him the full use of his own rich library. The friendship of such a man soon procured him further advantages. The son of Professor Rudbeck, and other young men, became his private pupils, by which his finances were improved. Nothing however seems to have been recollected with so much satisfaction to himself, in relating the events of this part of his life, as his intimate scientific friendship with Peter Artedius, who afterwards called himself Artedi, and became to famous in the knowledge of fishes and of umbelliferous plants. They passed some time together subsequently in Holland, when Linnæus witnessed the melancholy fate of his friend, who was accidentally drowned at Amsterdam; of which he has prefixed so pathetic an account to the *Ichthyologia* of Artedi, published by his means.

During his studies, under the roof of Celsius, Linnæus met with a review of Vaillant's treatise on the Sexes of Plants, which first led him to consider the importance, and great varieties of form, of the stamens and pistils, and thence to form a new scheme of arrangement founded on those essential organs. He drew up an essay in opposition to the librarian of the university, who had published a work *de Nuptiis Plantarum*, and shewed it to Celsius, who communicated it to Rudbeck, and the performance was honoured with the high approbation of both. This led the way to his being appointed to lecture in the botanic garden, as an assistant or deputy to the latter, whose advanced age rendered some relaxation necessary. The lectures of Linnæus began in the spring of 1730. He had previously solicited from the Professor the humble appointment of gardener to the university, which was refused, only on the ground of his being fit for a better situation. Now finding himself authorized to take the direction of the garden, he reformed and greatly enriched it. He was taken into the house of Rudbeck, as tutor to his younger children, and by this means had the use of a very fine collection of books and drawings. His mornings being devoted to the duties of his station, his evenings were spent in preparing some botanical works. It was now that he began to write his *Bibliotheca Botanica*, *Classes Plantarum*, *Crucis Botanica* and *Genera Plantarum*, though these books were not given to the world till about seven years afterwards, when he printed them in Holland, during his stay there.

A new object now engaged all the attention of our emulous young naturalist. The conversations of Rudbeck, concerning the natural history of England, and the curiosities he had seen there, excited an insatiable desire in Linnæus to visit the same country. To this he was perhaps the more immediately prompted, by some little circumstances, which

made his residence at Upsal uncomfortable. These were, the jealousy of Dr. Rosen, who was ambitious of succeeding Rudbeck whenever his Professorships should become vacant, and who by his success as the only practising physician at Upsal, was likely to prove a formidable rival; as well as some domestic chagrin, which he thus relates. "The faithless wife of the librarian Norrelius lived at this time in Rudbeck's house, and by her Linnæus was made so odious to his patroness, that he could no longer stay there."—In the end of the year 1731 he retired to his native place, and soon received, from the Academy of Sciences at Upsal, an appointment to travel through Lapland, under the Royal authority, and at the expence of the Academy.

After a visit to Lund in the spring of 1732, Linnæus set out from Upsal, May 12th, on his Lapland expedition. He travelled on horseback, but slenderly provided with baggage, and after visiting the Lapland alps on foot, and descending to the coast of Norway, of which he has given a most picturesque and striking description, returned by Tornea, and the east side of the Bothnian gulf, to Abo, and so to Upsal, which he reached on the 10th of October, having performed a journey of near 4000 English miles. The particulars of his interesting expedition have lately been given to the public, in an English translation of the original journey written on the spot, illustrated with wooden cuts from his own sketches, making two octavo volumes. This document, a faithful transcript of his own mind, and written solely for his own use, gives a most amiable and respectable idea of the character and acquirements of this celebrated man, at this period of his life.

Having learned the art of assaying metals during ten days' residence at the mines of Biörknäs, near Calix, in the course of his tour, he next year gave a private course of lectures on that subject, which had never been taught at Upsal before. The jealousy of Rosen, however, still pursued him; and this rival descended so low as to procure, partly by intreaties, partly by threats, the loan of his manuscript lectures on botany, which Linnæus detected him in surreptitiously copying. Rosen had taken by the hand a young man named Wallerius, who afterwards became a distinguished mineralogist, and for whom he now procured, in opposition to Linnæus, the new place of *adjunct*, or assistant, in the medical faculty at Lund. But the basest action of Rosen, and which proved envy to be the sole source of his conduct, was, that having married the niece of the archbishop, he obtained, through his lordship's means, an order from the chancellor to prevent all private medical lectures in the university. This, for which there could be no motives but conscious inferiority and malice, deprived Linnæus of his only means of subsistence, and the students of any information which might endanger their reverence for his rival. He is said to have been so exasperated, as to have drawn his sword upon Rosen, an affront with which the latter chose to put up, as, doubtless, became the prosperous nephew of an archbishop; but Linnæus cannot be excused of having, for some time afterwards, indulged feelings of passionate resentment, and even of meditated revenge. These, however, his better principles and dispositions, after a while, entirely subdued, and Rosen, towards the close of his life, was glad of the medical aid of the man he had in vain endeavoured to crush.

Disappointed in his views of medical advancement, Linnæus turned his thoughts more immediately to the subject of mineralogy. In the end of the year 1733, he had visited some of the principal mines of Sweden, and had been introduced to Baron Reuterholm, governor of the province of Dalecar, or Dalecarlia, resident at Fahlun. This place

Linnæus has perpetuated in the memory of botanists, by his *Lichen Fahlunensis*, a production more resembling some ramification of the neighbouring copper ores, than any thing of vegetable origin. At the persuasion, as well as at the expence, of the governor, he travelled through the eastern part of Dalecarlia, accompanied by seven of his ablest pupils, and the unpublished journal of his tour exists in his library. At Fahlun he gave a course of lectures on the art of assaying, which was numerously attended, and here he first became acquainted with Browallius, then chaplain to the governor, afterwards bishop of Abo. This judicious friend advised Linnæus to take his doctor's degree, in order to pursue the practice of physic, in which he had already at Fahlun met with much success, and he further recommended him to aim at some advantageous matrimonial connection. Dr. John Moræus, a physician of the place, though at first not prepossessed in favour of our young adventurer, whose medical success had encroached on his own, allowed him to pay his addresses to his eldest daughter; but their union was for the present deferred.

In pursuit of the plan pointed out by Browallius, Linnæus, having scraped together about 15*l.* sterling, now entered on his travels, with a view of obtaining his degree at the cheapest university he could find, and of seeing as much of the learned world as his chances and means might enable him to do. In the beginning of the year 1735 he set out, after visiting his father, lately become a widower, in company with another medical student, named Sobberg. At Hamburg his skill and honesty unfortunately stood in his way. The brother of one of the burgomasters was possessed of a specimen of that reputed wonder, a Hydra with seven heads, the awe and admiration of all who beheld it, upon which its owner, in the true mercantile style, had fixed an enormous hypothetical value. His golden dream was destroyed by Linnæus, who proved the monster to be artificial.

After a stay of eight days at Amsterdam, Linnæus proceeded to Harderwyck, where, having offered himself as a candidate, and undergone the requisite examinations, he obtained his degree June 23, 1735. On this occasion he published and defended a thesis, entitled *Hypothesis Nova de Febrium Intermitantium Causâ*, in the dedication of which, to his *Mæcenates et Patronos*, it is remarkable that, among the names of Rudbeck, Rothmann, Stohæus, Moræus, &c. we find that of Rosen. The hypothesis here advanced, most correctly so denominated, is truly Boerhaavian. Intermittent fevers are supposed to be owing to fine particles of clay, taken in with the food, and lodged in the terminations of the arterial system, where they cause the symptoms of the disorder in question. If we smile at the theory, we cannot but admire the ingenuity with which it is supported, and the extent of the author's knowledge and observation; nor is the theory itself at all less respectable, than those which make a figure in the humoral pathology, universally taught at that period, by some of the greatest medical philosophers of any age.

In Holland Linnæus became acquainted with Dr. John Frederick Gronovius (see GRONOVIV.), who assisted him in publishing the first edition of the celebrated *Systema Naturæ*, consisting of eight large sheets, in the form of tables; which edition is now a great bibliothecal curiosity. He also procured access to the illustrious Boerhaave, who encouraged him to remain in Holland; but this advice could scarcely have been followed, had he not met with a patron in Burmann, of Amsterdam, who was then preparing his *Thesaurus Zeylanicus*, and who received Linnæus into his house, as his guest for some months, during which period he printed his

Fundamenta Botanica, a small octavo of 36 pages, in the form of aphorisms, which contains the very essence of botanical philosophy, and has never been superseded nor refuted. The subsequent performances of the author himself, and of his followers, have been excellent, in proportion as they have kept to the maxims of this little book. After Linnæus had been a few months under professor Burmann's roof, he was introduced by Boerhaave to Mr. George Clifford, an opulent banker, whose garden at Hartecamp was one of the richest in the world, and who thought himself happy in the opportunity of procuring such a man to study and superintend his collection, as well as to make known to the world any novelties it might contain. Linnæus was therefore removed to Hartecamp, where, as he says, "he lived like a prince," more glorious, no doubt, than an Asiatic despot, in the innumerable vegetable tribes which daily offered their homage at his feet. With an ample library, as well as garden, at his command, in both which he had unlimited powers to supply any defects that he might discover, he had now the means of cultivating his beloved science without restriction or impediment, and appears to have been truly sensible of the happiness of his lot. He now wrote and printed his admirable *Flora Lapponica*, the plates of which were supplied by the contributions of a society at Amsterdam. This work, one of the happiest literary compositions of its author, is strikingly characteristic of the state of his mind at the time it was written. It is redundant in observation and reflection, on every subject which could be interwoven with its professed object, conveyed in the most engaging style; a style independent of studied phraseology, flowing directly from the heart, and deriving its principal charm from the delight which the author takes in what he has to communicate. The enthusiasm with which his imagination retraces every idea of his Lapland expedition, turns the wild scenes of that country, even in the mind of his reader, into a paradise, inhabited by all that is innocent and good. His effusions resemble the longings of an exiled Swiss; and are in fact incipient symptoms of that oppression of the heart, which, after a while, rendered his abode in Holland, with all its scientific charms, no longer tolerable, to one born in the purer air of Sweden, and nurtured amongst her Lapland alps.

The prosperous condition of Linnæus, under the patronage of Mr. Clifford, afforded him much more than a selfish gratification, when he met with his old friend Artdi, at Amsterdam, destitute of the means of prosecuting his studies, obtaining his degree, or even of supporting himself with credit or decency. "He had spent all his money in London;" an accident not peculiar to a poor Swedish student; and would now have been destitute but for the exertions of his friend, who recommended him to Seba, to whom the learning and abilities of Artdi were peculiarly serviceable, in completing the third volume of his magnificent *Thesaurus*, chiefly devoted to fishes. We have already alluded to the unfortunate catastrophe of this young man, and a short sketch of his life is given in its proper place. See ARTEDE.

In 1736, after having written his *Musa Cliffortiana*, Linnæus was sent by Mr. Clifford to England, and was introduced to the lovers and teachers of natural science, at Oxford and London more especially. Of his reception from the Sherardian Professor, we have already spoken. (See DILLENIUS.) He was strongly recommended by Boerhaave, in a letter which still exists, to sir Hans Sloane; but this indefatigable collector neither understood nor cared for these improvements in botanic science which he might have learned from his visitor. Linnæus found more intel-

ligent and communicative friends in Dr. Shaw, the oriental traveller, professor Martyn the elder, the well-known Philip Miller, and the celebrated Peter Collinson. (See COLLINSON.) These men of true science admired his genius and valued his friendship; they promoted his wishes by every means in their power, enriching him with books; and supplying him plentifully with plants, both for his own herbarium, and the garden of his patron at Hartecamp. He was much struck with what he saw of London, and has celebrated it in an expression which has often been repeated, calling this famous city the "*pneûm saliens in vitello orbis*." Of his observations on the natural history of this country, nothing is preserved but a tradition, that the golden bloom of the furze on the commons near London, especially Putney-heath, delighted him so much, that he fell on his knees in a rapture at the sight. He was always an admirer of this plant, and laboured in vain to preserve it through a Swedish winter in his greenhouse; as we in England are obliged to shelter the Cape shrub in a stove, though it covers walls in the open air at Paris.

On his return to Holland, he continued the impression of his *Genera Plantarum*, which appeared in 1737. In October, 1736, he was made a member of the Imperial Academy *Natura Curiosorum*, by the title, according to the custom of that body, of Dioscorides secundus. He was now tempted by Boerhaave to undertake a botanical expedition to the Cape of Good Hope and to America, at the public expence, and flattered with the expectation of a Professorship in Holland at his return; but he neither chose to encounter the hazards of the undertaking, nor to give up his prospects at home. He would not however leave the benefactor to whom he owed so much, till he had accomplished all that was to be expected from him. He printed in 1737 the *Viridarium Cliffortianum*, an octavo catalogue of his friend's garden, disposed according to his own sexual system; of which he published, later in the same year, at Leyden, an exemplification under the title of *Methodus Sexualis*, in which all the known genera of plants are so arranged by name only. This year also produced his magnificent *Hortus Cliffortianus*, in folio, in which all the plants of Mr. Clifford's collection, whether living or dried, are enumerated, with many descriptions and highly interesting remarks, an almost complete detail of synonyms, and some of the most exquisite plates ever seen in any book. This splendid volume was not published, but only given away by Mr. Clifford. It was begun and completed in nine months. In the intervals of this labour the *Critica Botanica*, an octavo volume, was written and printed. This is an entertaining commentary and illustration of part of the *Fundamenta*, from section 210 to 324, relating to nomenclature and specific characters. It is a book not so much known as it deserves, being very rare. These severe labours however proved too much for the health of Linnæus, and he conceived that the autumnal air of Holland, as is very probable, did not agree with him. Though he had every luxury and indulgence at his command, and was caressed by his patron, and by all who came near him, with the most flattering attentions, he longed to return to his native country. Having left Mr. Clifford, he could not refuse his assistance for a while to Professor Adrian Van Royen at Leyden, in the arrangement and description of the garden there, which seems rather to have displeased his late patron, and not perhaps without reason, after the strong inducements he had offered to retain him. Linnæus excused himself as well as he could, and while giving his assistance to Van Royen, composed and printed the *Classes Plantarum*, which is a complete view of all the botanical systems ever known. Here also he published his friend Artdi's

Artedi's *Ichthyologia*. Boerhaave made another attempt to induce him to visit some exotic regions, offering him a medical appointment at Surinam, which it is happy he did not accept. His friend and great favourite Barfch, who was sent in his stead, fell a sacrifice to the climate, and to the neglect and ill usage he received from the governor, as Linnæus has feelingly related in his *Flora Suecica*, under the genus *Barfcha*.

Linnæus remained at Leyden till the spring of 1738, when he had an interesting interview with the great Boerhaave, then on his death bed. "I have lived out my time," said the venerable invalid. "I have done what I could, may God preserve thee, from whom the world expects much more. Farewell!" Whether the climate of Holland co-operated with dejection of spirits in our young Swede, in consequence of news he received respecting a rival in the affections of his mistress, and in the esteem of his intended father-in-law, or whether his literary labours were too unremitting, his departure was prevented by a very formidable intermittent fever. The skill of Van Swieten, and the renewed attentions of the amiable Clifford, who received him again under his roof with the most liberal and indulgent kindness, after some weeks restored him so far, that he was able, though still weak, to set out on his journey. On reaching the more elevated country of Brabant, he felt in one day quite renovated, his whole frame being, as he expresses it, "freed from some great burthen." He carried a very handsome introductory letter from Van Royen to Anthony de Jussieu, the physician, who made him acquainted with his brother, the famous Bernard de Jussieu. (See JUSSIEU.) He inspected the botanic garden, the herbariums of Tournesfort, Vaillant, the Jussieus, &c.; visited the neighbourhood of Fontainebleau, which he has celebrated for its *Orchidea*, formed an acquaintance with Reaumur and other distinguished naturalists, and was admitted a corresponding member of the *Académie des Sciences*.

How he conversed with Reaumur and others, who knew no language but their own, and for the same reason, how he contracted so close a friendship with Mr. Collinson at London, it is not easy to conceive. He confesses a peculiar inaptitude, and, we think, a blameable indifference, for the learning of languages, declaring in his diary that in all his travels he learnt "neither English, French, German, Laplandish, nor even Dutch, though he stayed in Holland three whole years. Nevertheless, he found his way every where, well and happily." By the journal of his Lapland tour, and other manuscripts, it appears that Latin was sufficiently familiar to him; and if fastidious critics, who are not competent to follow his ideas, may sometimes censure the style of part of his writings, they have chiefly taken their liberty with the *Amoenitates Academicæ*, not remarking the great variety of style in the essays which compose those volumes, and which are chiefly writ en by the pupils whose inaugural dissertations they were. The matter indeed was mostly communicated by the Professor, whose office it was to defend each thesis, in conjunction with the candidate, against all opposers. Thus these essays are always quoted as the works of Linnæus, though their language is rarely his own; and is indeed so various, that it could not be supposed all to come from one author.

After leaving Paris, Linnæus took his passage at Rouen for Sweden, and landed at Helsingborg, from whence he proceeded to Fahlun, visiting his father for a few days in his way. His reception from the lady of his choice was favourable, and they were formally betrothed to each other. Before they could marry, it was necessary that some prospect of an advantageous establishment should be discovered.

Stockholm was thought a promising theatre for a young man of talents in the medical profession, but talents are usually what those who employ a young physician, are of all things least able to judge of. If fortune or prejudice do not stand his friend, the skill of Hippocrates, Celsus or Boerhaave will scarcely be discerned. The scientific merits of Linnæus were not overlooked, as he was unanimously chosen a member of the Upsal academy, the only one then in Sweden; yet the homage he had so lately received abroad, seems to have made him a little unreasonable on this head, and he declares that he would certainly have quitted his native country, "had he not been in love." To this all-powerful deity therefore, and not to his merits, or to the wisdom of his countrymen in discerning them, was Sweden, in the first instance, indebted for the possession of her Linnæus. From his country however flowed his most abundant reward; for whatever emolument his matrimonial connexion might afford, it certainly brought him little happiness or honour. After passing the winter of 1738 in the capital, he began to make his way in some departments of medical practice, so that by the following March he had considerable employment. At this time a plan was formed for establishing a literary society at Stockholm, which afterwards rose to great eminence, and still continues to flourish, having published numerous volumes of Transactions, in the Swedish language. Triewald, Höpken and Alstroem, (whose family was ennobled by the name of Alstroemer.) were, with Linnæus, the first members: and the infant society, being incorporated by royal authority, was augmented with all the most learned men of the country. Its objects were declared to be natural philosophy, natural history in all its branches, chemistry, medicine, anatomy, surgery, mathematics, economy, commerce, arts and manufactures. So wide a range might have been feared to have endangered its success; but though, in its progress, these various studies have, from time to time, predominated by turns, they seem not to have clashed with each other. Part of its transactions has been published in Latin at Venice, under the title of *Analeſta Tranſalpina*, which is some reproach to other countries of Europe, where they are so very little known.

A most flattering mark of public approbation was, soon after, conferred on Linnæus, without any solicitation. Count Tessin, marshal of the Diet, which was then sitting, gave him an annual pension of 200 ducats from the board of mines, on condition of his giving public lectures on botany and mineralogy at Stockholm. The same nobleman also obtained for him the appointment of physician to the navy, and received him into his house. His practice now increased greatly among the nobility, and he found himself in so prosperous a condition that he would no longer delay his marriage, which took place at Fahlun, June 26. 1739. After a month he returned to Stockholm. He was, by lot, the first president of the new academy; and as that office was to be but of three months' duration, after the French plan, he resigned it in September, and on that occasion delivered an oration in Swedish, on the wonderful Economy of Insects, which was printed in the Transactions; and a Latin version of it may be found in the *Amœnitates Academicæ*, v. 2. His example was followed by all the succeeding presidents.

The death of professor Rudbeck in 1740, gave Linnæus a hope of succeeding to the botanical chair at Upsal, one of the greatest objects of his ambition. The prior claims of his former rival, Rosen, on account of his standing in the university, could not however be set aside. Wallerius also rose up in opposition to the claims of Linnæus. It happened however that Roberg resigned the professorship of physic about this time, and by the exertions of count Tessin, who

who applied to the chancellor, count Gyllenborg, a compromise took place. Rosen obtained the professorship of botany, and Linnæus that of medicine, whilst Wallerius gained only censure for the illiberality with which he had prosecuted his claims. By an amicable adjustment which was confirmed by authority, the two new professors afterwards divided their official duties between them, so as best to suit the talents of each.

A war chancing to break out between Sweden and Russia, Linnæus was apprehensive that he should be obliged to attend the fleet, instead of which however, he received the much more agreeable order to travel through *Æland*, *Gothland*, &c. for the purpose of investigating the natural history and produce of those countries. He was accompanied by six of his pupils, and spent four months of the summer of 1741 in his expedition, of which an account was published at Stockholm in 1745; before he began his lectures at Upsal, to which place he removed in the autumn, he delivered a Latin oration "On the Benefit of travelling in one's own Country," printed in the 2d vol. of the *Amazitates*, and translated by Mr. Stillingfleet in his Miscellaneous Tracts. This composition has been much and justly admired.

The next year Linnæus undertook the reform of the Upsal garden, a new green-house was erected; an old house of stone, built by the great Olaus Rudbeck, who, having suffered so much by fire, would not admit a bit of wood into the structure, "was converted," as Linnæus says, "from an owl's nest into a lodging fit for the Professor." In 1743 the garden was in a state to receive those copious supplies of exotics, which the new Professor, in consequence of his extensive foreign correspondence, was enabled to procure. He was this year chosen a member of the academy at Montpellier. His reputation continued to increase both abroad and at home; he became secretary of the Upsal academy, and was employed on some public occasions to do the honours of the university. The death of his father-in-law obliged him to pay a visit to Fabun, but he seems to have gained little by this event, except the old medical library of Dr. Moræus, which still makes a part of his own. In 1746 he travelled to West Gothland; an account of his journey, which occupied two months, was published the following year.

In 1745 Linnæus published the first edition of his *Flora Suecica*, and in 1746 his *Fauna Suecica* came out. These works are models for such compositions, especially their second editions, published many years afterwards, with specific names, and many valuable additions.

A medal of this distinguished man was struck by some of his friends in 1746, dedicated to count Tessin. He soon after received the rank and title of Archiater, unsolicited, from the king, and was the only Swede chosen into the new-modelled academy of Berlin. All these honours, however, though he was by no means indifferent to such, appear to have given him less delight at this moment, than the acquisition of the herbarium made by Hermann in Ceylon, which an apothecary at Copenhagen unknowingly possessed. Being desirous of becoming better acquainted with the nature of this collection, its owner was recommended to Linnæus, who soon discovered to whom it had originally belonged, and rejoiced at recovering a treasure which had been supposed irrecoverably lost. He laboured day and night, as he tells us, in examining the flowers, and hence originated his *Flora Zeylanica*, published at Stockholm in 1747. This herbarium, as well as that of Chisford, is now in the possession of Sir Joseph Banks.

The exertions, and domestic as well as foreign reputation, of Linnæus, had now rendered botany extremely popular

in Sweden, and its interests were combined with those of commerce in various distant expeditions and speculations. Many of the principal merchants, as well as the nobility, had acquired a taste for natural history, and were proud to further the views of their distinguished Professor, who was now considered an honour to the nation. Several of his most intelligent pupils were sent to such distant countries, as he thought most worthy to be explored; as the East Indies, China, North and South America, and the Holy Land. (See HASSELIQVIST, KALM, and LÖFELING.) Their discoveries enriched his works and his herbarium. The latter also received important and very interesting communications from Gmelin and others, who had visited Siberia, and the original collections of Magnol and Sauvages were transmitted from Montpellier. Gronovius also furnished many Virginian specimens, gathered by Clayton. Such communications, from all parts of the world, grew more and more frequent as Linnæus advanced in life, as did also the academical honours which every literary body was proud to confer upon him. In 1749 appeared his *Materia Medica*, written in the same systematic and didactic style as the rest of his works. Of this numerous editions have been published on the continent, but none with any additions or corrections from the author himself, though he has left behind him copious manuscript notes on the subject. By the curious frontispiece of this book, one would suppose that he laughed in his sleeve at the state of medical practice in the world, though the body of the work proves he laboured very seriously to improve it. This year he travelled through Scania, &c. and, two years afterward, published an account of this tour, as he had done of the former. It is much to be regretted that these travels of Linnæus are not given to the world in a language more generally understood. There are German translations of them, but we know of no others. He was this year rector of the university, and it was memorable to him also for an attack of the gout, so violent as to endanger his life. He always attributed his restoration from this fit, and other subsequent ones, to his eating wood strawberries, the only sort, then at least, known in Sweden. Of this fruit his servants were ordered to purchase, throughout the season, all that were brought to his door, and it made a principal part of his diet.

To this attack of the gout, however distressing to the patient, the world is indebted for one of his most valuable and remarkable works, the *Philosophia Botanica*. The substance of this book must have been comprehended in the mind of its author when he wrote his *Fundamenta Botanica*; of which it is professedly a dilatation or exemplification, in the form of a commentary on each aphorism throughout. But, though he had long meditated on the subject of this publication, which embraces the whole range of botanic science, and indeed all the principles of natural knowledge; he had made but a few notes, not being able to digest or select his ideas, sufficiently to his own satisfaction, to communicate them to others. This illness however prompted him to rescue from the grave, to which he supposed himself hastening, whatever might be of service to those he left behind; and his pupil Lœfling was employed, sitting by his bed-side, to write down whatever the intervals of his sufferings would allow him to communicate. The manuscript afterwards received his own corrections, and the book came out in 1751.

About this period the queen of Sweden, Louisa Ulrica, sister to the great Frederick of Prussia, having a taste for natural history, which her royal consort king Adolphus Frederick also patronised, shewed much favour to Lin-

næus. He was employed in arranging her collection of insects and shells, in the country palace of Drotningholm, or Ulricksdahl, and was frequently honoured with the company and conversation of their majesties, during his attendance there. The queen interested herself in the education of his son, and promised to send him to travel through Europe at her own expence. She also listened very graciously to any recommendation or petition of Linnæus, in the service of science; redeeming the papers and collection of Hasselquist, and causing Kæhler to be sent to the Cape of Good Hope; whose mission however was rendered abortive by the jealousy of the Dutch, though he forwarded many curious insects and plants to his mailer from Italy. Linnæus devoted some of his leisure time in winter, to the arrangement of his friend count Tessin's collection of fossils, at Stockholm, of which an account in Latin and Swedish, making a small folio, with plates, came out in 1753. The result of his labours at Drotningholm was not given to the public till many years after, in 1764, when his *Museum Regium* appeared, in 8vo being a sort of *Prodromus* of an intended more splendid work, that was never executed. His most magnificent publication appeared in 1754, being a large folio, entitled *Museum Regis Adolphi Fredrici*, comprehending descriptions of the rarer quadrupeds, birds, serpents, fishes, &c. of the king's museum, in Latin and Swedish, with plates, and an excellent preface. This preface, one of the most entertaining and eloquent recommendations of the study of nature, that ever came from the pen of an enthusiastic naturalist, was translated into English by the writer of the present article, and first printed in 1786; appearing again, in a volume of *Traacts relating to Natural History*, in 1798. The queen of Sweden took so much pleasure in the conversation of her distinguished naturalist, that she allowed him his habitual indulgence of smoking, even in her apartments, that he might continue his labours with the more ease and satisfaction to himself. He was in every respect politely treated, as a visitor to his royal mistress, nor were his services accepted, without suitable returns of royal munificence. Whether, however, he felt not so entirely at ease as in his own study, or his attention was distracted by a variety of objects, the *Museum Regium* is certainly not one of his most correct works, as those who study its *Lepidoptera* and shells, with critical care, will not fail to discover.

In the mean while, this eminent man was preparing a lasting monument of his own talents and application, which even his rival Haller nobly denominates "*maximum opus et æternum*," the *Species Plantarum*, of which the first edition was printed in 1753, the second in 1760, each in two volumes 8vo. The work is too well known to need any description, but besides its importance as a complete arrangement and definition, with all necessary indication of synonyms, of every plant of which its author had any satisfactory knowledge, it is ever memorable for the adaptation of specific, or as they were at first called, trivial names. This contrivance, which Linnæus first used in his *Pan Suecicus*, a dissertation printed in 1749, extended to minerals in his *Museum Tessinianum*, and subsequently to all the departments of zoology, has perhaps rendered his works more popular than any one of their merits besides. His specific differences were intended to be used as names; but their unavoidable length rendering this impracticable, and the application of numeral figures to each species, in Haller's manner, being still more burthenome to the memory, all natural science would have been ruined for want of a common language, were it not for this simple and happy invention. By this means we speak of every natural produc-

tion in two words, its generic and its specific name. No ambiguous comparisons or references are wanted, no presupposition of any thing already known. The distinguishing character of each object is usefully stamped in its name; and if this perfection of the art cannot always be attained, the memory is assisted, often very ingeniously, with collateral information, indicating the colour, the habit, or the qualities of the object of our examination. The philosophical tribe of naturalists, for so they are called by themselves and their admirers, do not therefore depreciate Linnæus, when they call him a nomenclator. On the contrary, they celebrate him for a merit which no other person has attained, and without which their own discoveries and remarks, of whatever value, would not be understood. Neither can some of his fellow labourers, in the discriminative department of natural science, be justified, for either slighting this invention, or giving the credit of it to others. The method of Rivinus is not the same; as he designed his names for specific characters, to which purpose they are necessarily, from their brevity, inadequate. Whatever may have been thought of the Linnæan trivial names at their first appearance, they are now in universal use, and their principle has been, with the greatest advantage, extended to chemistry, of which the celebrated Bergman, the friend of Linnæus, originally set the example.

These herculean literary labours, combined with the practice of physic, were more than the bodily constitution of Linnæus could support. He was attacked with the stone, and had also, from time to time, returns of gout. He considered the wood strawberry as a specific for both disorders, and they never greatly interfered with his comfort or his duties. On the 27th of April 1753, he received, from the hand of his sovereign, the order of the Polar Star, an honour which had never before been conferred for literary merit. A still more remarkable, if not more grateful, compliment was paid him not long after by the king of Spain, who invited him to settle at Madrid, with the offer of nobility, the free exercise of his religion, and a splendid botanical appointment. This proposal was conveyed to him in a handsome letter by the duke of Grimaldi, then prime minister, and was as handsomely declined by Linnæus, who declared, that if he had any merits, they were due to his own country. This patriotic moderation received its just reward in November 1756, when he was raised to the rank of Swedish nobility, and took the name of Von Linné.

The *Systema Naturæ* had already gone through nine editions in different countries. Its author had, for several years, a more ample edition of the animal department in contemplation, on the plan of his *Species Plantarum*, and this constituted the first volume of the tenth edition, published in 1758. The second volume, which came out the following year, was an epitome of the vegetable kingdom. Here the genera appear with short essential characters, and the species are noted by little more than their specific differences, with few references and no indication of their native countries. This same great and important work appeared still more enlarged, in a twelfth edition, in the year 1766: to this the Mineral kingdom was added in a third volume on the same plan with the first. We can readily pardon the self-complacency of its author, when, in his diary written for the use of his friend Menander, he calls the *Systema Naturæ* "a work to which Natural History never had a fellow." We may venture to predict that as this was the first performance of the kind it will certainly be the last; the science of natural history is now become so vast, that no man can ever take the lead again as an universal naturalist.

The emoluments of Linnæus by his various publications were not great. He is reported to have sold the copyright of most of them for a ducat, (about nine and sixpence,) a printed sheet. His different appointments, however, for he soon laid aside the general practice of physic, had raised him to a considerable degree of opulence. He purchased the estates of Hammarley and Söfja in 1758, for 80,000 dollars, above 2330*l.* sterling. He chose the former for his country residence, and there, some years afterwards, he lodged his museum, in a building of stone, secured from all danger by fire. There he received the visits of distinguished foreigners and admitted his favourite pupils; to several of whom he gave private courses of Lectures, and completely laid aside the state of the nobleman and professor while he discoursed with them on his favourite topics. In 1760 he could not resist the temptation of writing in support of his doctrine of the sexes of plants, a handsome premium being offered that year by the Petersburg academy, as it was supposed with a view to awaken his attention to the subject. His Dissertation was printed, and was translated into English in 1786, with notes, by the present possessor of his library. His patent of nobility did not receive his Majesty's sign manual till 1761, though it was antedated 1757. It was confirmed by the Diet in 1762, and he then took a coat of arms expressive of the sciences he cultivated. That august body honoured him with a still more solid reward, upwards of 520*l.* sterling, for what seems to have been the least valuable of his discoveries, the art of producing pearls in the river muscle. This was accomplished by wounding the shells in their natural situation, as appears by some specimens illustrative of it in his museum, but the practice does not seem to have been prosecuted to any great extent.

He now became one of the eight foreign members of the French Academy of Sciences, an honour never before conferred on a Swede. Amid all his dignities however, his fondness for botany never declined; he records in his diary that having made many trials in vain to obtain the tea plant alive, he succeeded at length in 1763, adding "that God blessed him even in this point." His view indeed was patriotic as well as botanical, aiming at bringing this shrub into cultivation with us, so as, to use his own expression, "to shut the gate through which all the silver went out of Europe." It is much to be regretted that, from some peculiarity in the constitution of this precious vegetable, all attempts to reconcile it to the climate of any part of Europe have proved of no avail, at least as to any economical purpose.

In 1763 Linnæus was permitted to avail himself of the assistance of his son, now 21 years of age, in the labours of the Botanical Professorship, and the young man was thus trained up for his future successor. His eldest daughter was married to an officer in 1764. His worldly concerns appear to have been in a prosperous train, except that he suffered this year from a dangerous attack of pleurisy; but it is pleasing to read, in his private memorandums, the gratitude he expresses to his old rival Rosen, for his skill and attention during this illness, and the expressions of intimate regard by which they were now become attached to each other.

This year the sixth edition, by far the most complete, of the *Genera Plantarum* was published, nor did its author ever prepare another. It was intended as a companion to the *Species Plantarum*, but was greatly superseded by the more concise and commodious short characters of genera, given in the vegetable part of the *Systema Naturæ*. This last-mentioned part was subsequently prepared, under the inspection of Linnæus, for publication by his pupil Murray

of Göttingen, with the title of *Systema Vegetabilium*, edition 13th, and printed in 1774. A 14th edition, with additions from Jacquin and Thunberg, was published in 1784. Into these editions were interwoven the new species described by Linnæus in his first and second *Mantissæ*, two little volumes, containing additions and corrections, by way of supplement to the *Species Plantarum*. In them we cannot help perceiving a decline of the wonted precision and genius of their author, especially in the latter part of the second *Mantissa*, many remarks in which are misapplied, to plants different from what were intended, and the errors to which they give birth can be unravelled by the inspection of the Linnæan herbarium only.

Though Linnæus declares, in his diary, that he gave up the general practice of physic, on his establishment at Upsal, attending only his friends and the poor, he appears ever to have paid great attention to that noble and intricate science. His lectures on medicine, dietetics, and the animal economy, were in high repute, nor is he at all behind-hand in commending his own abilities in this line. Though undoubtedly a great and sagacious observer in every department of nature, he was in this somewhat too theoretical. If, however, he had peculiar ideas respecting the prevalence of the number five, his hypotheses in general rose much above the dull level of the humoral pathology in which he was educated; and when he applies his own didactic talents to illustrate medical theories, or any thing else, he is always ingenious, and as luminous as the subject will allow. His curious little *Clavis Medicinæ*, published in 1766, and his *Genera Morborum*, which appeared three years before, are not only striking, but instructive. His idea of a systematic arrangement of diseases by technical characters, was followed up and illustrated on a large scale, by his friend Sauvages of Montpellier; and the celebrated Dr Cullen of Edinburgh, justly attributed to the Swedish philosopher the foundation of his own performance in this line. Such schemes of arrangement indeed can be considered merely as helps to the memory, and in themselves altogether artificial. The abilities of Linnæus appear to the greatest advantage in his classification of natural objects. He excelled in a happy perception of such technical characters, as brought together things most naturally allied. Thus his sexual distribution of plants, though professedly artificial, is in many parts as natural as any that pretends to be so. Linnæus, moreover, was the first who perceived and declared the distinction between a natural and an artificial botanic system, and he has laboured at the one as much as at the other. His lectures on the natural orders of plants were published, long after his death in 1792, from the notes of his pupils Giseke and Fabricius, at Hamburg. They evince his deep consideration of a subject, then in the infancy of cultivation, the intricacy of which may well excuse the frequency of error in the detail. In the zoological department, it is but justice to observe, that his classifications of birds and insects are the most original as well as the best of the whole. In the former, as in the *Mammalia*, the organs of feeding lead the way to the most natural distinctions possible; but the author of this system, which no one has yet attempted to supersede, was well aware that the same principle would not hold good throughout, particularly with respect to insects, whose destination, in their perfect state, is not so much to take food, as to propagate their species. The mouth and its appendages are therefore, in this tribe, but of far subordinate consequence; and Linnæus had recourse to the more natural, as well as far more easy principles, deducible from the chief peculiarities of these animals, the differences in their wings, their legs, and their *antennæ*. His pupil Fabricius,

for this reason, however able and ingenious in entomology, cannot be considered as fortunate or philosophical, in applying his great preceptor's scheme of arrangement of quadrupeds and birds to insects. Indeed, those who have followed Fabricius in the detail of this study, declare, that he has rarely proceeded on his own plan, but, leaving the mouth in most cases unexamined, has trusted to habit and general configuration, which certainly produce natural assemblages enough, and true to the Linnæan rules, but different from his own. The arrangement of fishes, by the relative position of their ventral fins, was a no less happy and original idea of the Swedish naturalist; as pointing out their leading differences of form and habit, by a distinctive character, taken from a peculiar organ of their own. Shells he was long before he would study minutely at all, considering them merely as the houses of particular animals, the knowledge of whose structure and economy was, in a great measure, inaccessible. At length, however, the uniformity of his plan obliged him to class these popular objects of admiration, in some way or other, and he has succeeded at least as well as any of his fellow-labourers; though we are by no means inclined to justify some of his terms, which are borrowed from an anatomical analogy, not only false in itself, but totally exceptionable. This leads us to consider a charge, often brought against this great man, of pruriency of phraseology in many parts of his works. The most attentive contemplation of his writings has satisfied us that in such instances he meant purely to be anatomical and physiological, and if his fondness for philosophical analogies sometimes led him astray, it was not in pursuit of any thing to contaminate his own mind, much less that of others. "Some of the descriptions of Linnæus," says a noble botanical author, "would make the most abandoned person blush." His lordship ought to have added, "*none but* the most abandoned." That the mind of Linnæus was simple and chaste, as his morals were confessedly pure, is evinced by his Lapland Tour, written only for his own use, but which is now, as we have already mentioned, before the public. This is such a picture of his heart, as will ever render any justification of his moral character, and any elaborate display of his religious principles or feelings, alike superfluous.

His apparent vanity, as displayed in his diary, published in Dr. Maton's valuable edition of Dr. Pulteney's *View of his Writings*, is perhaps far less justifiable. All we can say for him is, that this paper was drawn up for the use of his intimate friend Menander, as materials from which his life was to be written. If it be unbecoming, and indeed highly ridiculous in many instances, for a man to speak as he does of himself, the justice and accuracy of his assertions, had they come from any other person, could in no case be disputed.

As the habits of Linnæus were temperate and regular, he retained his health and vigour in tolerable perfection, notwithstanding the immense labours of his mind till beyond his 60th year, when his memory began in some degree to fail him. In 1774, at the age of 67, an attack of apoplexy greatly impaired his constitution. Two years afterwards a second attack rendered him paralytic on the right side, and materially affected his faculties. The immediate cause of his death, which happened January 10th, 1778, in the 71st year of his age, was an ulceration of the bladder. His remains were deposited in a vault near the west end of the cathedral of Upsal, where a monument of Swedish porphyry was erected by his pupils. His obsequies were performed, in the most respectful manner, by the whole university, the pall being supported by sixteen doctors of physic,

all of whom had been his pupils. A general mourning took place on the occasion at Upsal. His sovereign, Gustavus III. commanded a medal to be struck, expressive of the public loss, and honoured the Academy of Sciences at Stockholm with his presence, when the eulogy of this celebrated man was pronounced there by his intimate friend Bäck. A still higher compliment was paid to his memory by the king in a speech from the throne, wherein his majesty publicly celebrated the talents of his deceased subject, and lamented the loss which his country had so recently sustained. Various testimonies of respect were given to the merits of Linnæus in the different parts of Europe, even where rival systems or interests had heretofore triumphed at his expence. The celebrated Condorcet delivered an oration in his praise to the Parisian Academy of Sciences, which is printed in its memoirs. We cannot wonder that his memory was cherished in England, where he had long had numerous correspondents, and where two of his most distinguished pupils, Solander and Dryander, have, in their own talents and character, conferred singular honour upon their preceptor. Ten years after his decease a new society of naturalists, distinguished by his name, was founded in London, and has since been incorporated by royal charter, whose publications, in ten quarto volumes of Transactions, sufficiently evince that its members are not idle venerationers of the name they bear. This name, in imitation of them, has been adopted by several similar institutions in other parts of the world.

The appellation of Linnæan Society was, with the more propriety, chosen by this British institution, on account of the museum of Linnæus having fallen into the hands of its original projector, and hitherto only president. This treasure, comprehending the library, herbarium, insects, shells, and all other natural curiosities, with all the manuscripts and whole correspondence of the illustrious Swede, were obtained, by private purchase from his widow, after the death of his son in 1783. The authority which such an acquisition gave to the labours of the infant society, as well as to all botanical and zoological publications, the authors of which have ever been allowed freely to consult it, will readily be perceived. Nothing perhaps could have more contributed to raise up, or to improve, a taste for natural science, in any country.

Linnæus had by his wife Sarah Elizabeth, who survived to extreme old age, two sons and four daughters. His eldest son Charles succeeded him in the botanical professorship; see the next article. The younger, John, died March 7, 1757, in the third year of his age. The marriage of his eldest daughter, Elizabeth Christina, we have already mentioned. This lady is recorded as having discovered a luminous property in the flowers of the *Nasturtium*, *Tropæolum majus*, which are sometimes seen to flash like sparks of fire in the evening of a warm summer's day. Of the other daughters we know nothing materially worthy of record. The late Danish Professor Vahl is reported, when a student, to have made an impression on the heart of the young girl, which her father did not think proper to countenance, and which is supposed to have prevented his shewing that favour and encouragement to the young Dane, which his acuteness and zeal in botanical studies certainly deserved. Linnæus's Diary, published by Dr. Maton, with another in MS. of the early part of his life. Stoecker's Life of Linnæus by Trapp. Aikin's General Biography. Various works of Linnæus. S.

LINNÆUS, OF VON LINNÉ, CHARLES, the eldest, and only surviving son of the preceding, was born January 20, 1741, at the house of his father at Fahl n. His father was anxiously desirous of his excelling in natural

history, more particularly botany, and after endeavouring, from his most tender years, to make him fond of flowers, committed him, when about the age of nine or ten, to the more particular care of some of his own most favourite pupils. By them he was taught the names of the plants in the Upsal garden, and such of the principles of natural science as were suited to his period of life, as well as to converse habitually in Latin. He proved a docile and ready scholar, and appears to have given satisfaction to his father, who procured for him, at the age of eighteen, the appointment of Demonstrator in the botanic garden, an office then first contrived on purpose for him. Having learned to draw from nature, he became an author at the age of twenty-one, publishing in 1762 his first *Decas Plantarum Rariorum Horti Upsaliensis*, the plates of which, in outline only, like those of Plummer, were drawn by his own hand. These are sufficiently faithful and useful, if not ornamental. The descriptions are full and scientific. In 1763 another *Decas*, or collection of ten species, came out on the same plan. Whether the Upsal bookfellers did not encourage him to proceed, or for what other reason we know not, he never printed any more numbers under this title. In 1767 however, he published at Leipzig ten more plates and descriptions, like the above, entitled *Plantarum Rariorum Horti Upsaliensis Fasciculus Primus*. To this he was perhaps infligated by his friend Schreber, who, the year before, had given to the world a similar work, describing ten rare oriental plants, drawn by himself. But neither of these publications was ever extended to a second *Fasciculus*. In 1763 he was nominated adjunct Professor of Botany, with a promise, hitherto unexampled, that after his father's death, he should succeed to all his academical functions. In 1765 he took his degree of Doctor of Physic, and began to give lectures.

His progress would probably have been happy, if not brilliant, but domestic chagrin sapped the foundation of all his felicity, and damped his ardour in every pursuit. This arose from the conduct of his unnatural mother, another example of that rare and detestable depravity exhibited by the mother of Savage the poet. Not content with dishonouring her husband's bed, and making his home as uncomfortable as she could, by the meanest parsimony and disgusting petty tyranny, the wife of the great Linnæus conceived a hatred for her only son, which she displayed by every affront and persecution that her situation gave her the means of inflicting on his susceptible and naturally amiable mind. According to Fabricius, she forced her husband, who by such a concession surely partook largely of her guilt and meanness, to procure the nomination of his pupil Solander to be his future successor, in preference to his own son, and it was a part of her plan that he should marry her eldest daughter. Solander, however, disdained both the usurpation and the bait, refusing to leave England; and the misguided father recovered his senses and authority, causing his son, as we have said above, to receive this truly honourable distinction. The mind and spirit of the young man nevertheless still drooped, and even when he had attained his thirtieth year, he would gladly have escaped from his miseries and his hopes together. The authority of the king was obliged to be exerted, at his father's solicitation, to prevent his going into the army. This measure of the parent was happily followed up by kindness and encouragement in his botanical pursuits, to which treatment the son was ever sensible, and he revived from his despondency before his father's death, which happened when he was thirty-seven years of age.

Though obliged by his mother to purchase, at her own

price, the library, manuscripts, herbarium, &c. which he ought by every title to have inherited, he rose above every impediment, and betook himself to the useful application of the means now in his hands, for his own reputation and advancement. His father had already prepared great part of a third botanical Appendix, or *Mantissa*; from the communications of Mutis, König, Sparmann, Forster, Pallas, and others. To this the younger Linnæus added those of Thunberg from the Cape, which his father, "with half-extinguished eyes," as Condorcet beautifully relates, had just been able to glance over, but not to describe. Hence originated the *Supplementum Plantarum*, printed at Brunswick, under the care of Ehrhart in 1781. The ingenious editor inserted his own new characters of some genera of Mosses; which Hedwig has since confirmed, except that some of the names have been justly rejected. This sheet was, in an evil hour, suppressed by the mandate of Linnæus from London, where, at that period, the subject of generic characters of mosses was neither studied nor understood, whatever superior knowledge was displayed concerning their species. The plants of the *Supplementum* are admitted into the fourteenth edition of the *Syllaba Vegetabilium* by Murray, and figures of some of the most curious have been published by the writer of this present article, in his *Plantarum Icones ex Herbario Linnæano*. Three botanical dissertations also appeared under the presidency of the younger Linnæus, on Grasses, on *Lavandula*, and the celebrated *Methodus Muscorum*, which last was the work, and the inaugural thesis, of the present Professor Swartz of Stockholm. These form a sequel to the 186 similar essays, which most of them compose the seven volumes of the *Amoenitates Academica*, the rest being published by Schreber in three additional ones.

The subject of our memoir had always felt a strong desire to visit the chief countries of learned and civilized Europe. For this purpose he was obliged to pawn his juvenile herbarium, made from the Upsal garden, to his friend Alströmer, for the loan of about fifty or sixty pounds. He arrived at London in May 1781, and was received with enthusiasm by the surviving friends and correspondents of his father, and was in a manner domesticated under the roof of sir Joseph Banks, whose friendship, kindness, and liberality could not be exceeded; neither could they have been by any one more gratefully received. Here the ardent Swedish visitor had every assistance for the preparation of several works on which he was intent, as a system of the *Mammalia*, a botanical treatise on the Lily and Palm tribes, and new editions of several of his father's standard books. None of these however have yet been printed. An attack of the jaundice rendered half his stay in England uncomfortable as well as useless to him. He proceeded to Paris in the latter end of August 1781, accompanied by the amiable and celebrated Broussonet, with whom he became acquainted at London. His reception in France was not less flattering than what he had experienced in England. He was enriched with duplicates of Commerçon's plants from the herbarium of the excellent Thouin, which amounted to about 1100 species, and had never been communicated to any other foreigner. In the following spring he visited Holland, tracing with filial piety every vestige of his father's steps at Hartecamp and elsewhere, and receiving, as he had done at Paris and London, ample contributions for his herbarium, library, and museum of shells and insects. The next place in which he made any stay was Hamburg, where several of his own friends were already settled, and from hence he returned by Copenhagen and Stockholm, visiting his friend Fabricius at Kiel, and his patron Baron

Ailstroemer at Gottenburgh, finally arriving at Upsal in February 1783. In his progress he had received several academical honours, as well as ample testimonies of scientific and personal respect, being a man of agreeable and unassuming manners, without vanity or ostentation, though somewhat, perhaps not unduly, tenacious, that his own discoveries and performances should not be confounded with any thing left behind by his father. But the career of this excellent man was cut short by a bilious fever, which concluded with a stroke of apoplexy, November 1, 1785, in the forty-second year of his age. His remains were interred with great solemnity on the 30th of the same month. His coffin was laid by the side of his father, and as the male line of the family concluded in him, their coat of arms was broken over the grave. After this ceremony the gardener of the university strewed flowers over the mingled ashes of the father and the son. A funeral oration in Swedish was pronounced by M. Von Schulzenheim, and was soon after published. This composition, partly translated, and much enlarged, in the English edition by Trapp of Stoevner's Life of Linnæus, has afforded much of the substance of this article, assisted by several private communications.

The younger Linnæus is said to have had naturally a strong and vigorous frame of body, and to have inherited his father's keen and penetrating eyes, as well as his temper and active disposition. He was greatly beloved by those who knew him, and died generally respected and lamented. His museum and library reverted to his mother and sisters, as he had never been married; and the former instantly fixed her eyes on Sir Joseph Banks, as the most likely person to purchase these relics at the high price, as she thought it, of a thousand guineas. On his refusal, and by his kind recommendation and advice, they came into the hands where they now are. The sale was precipitated before the return of the king of Sweden, then on his travels, lest he should oblige the heirs to dispose of the whole at a cheaper rate to the University of Upsal. This would actually have been the case, as appears from the exertions made by his Majesty on his return, who sent a courier to the Sound, and a vessel by sea, to intercept the ship that was bearing away the prize. S.

LINNET, LINARIA, in *Ornithology*, the denomination of a tribe of birds, which some authors have made a distinct genus, comprehending several species, which are usually classed under the genus *Fringilla*. Those who consider them as a distinct genus, state their characters to be these: the birds of it are somewhat smaller than the chaffinch; their general colour is a greyish-brown; their tail is a little forked, the outer feathers of it having white extremities; and they all sing very sweetly. We have in England four species of this bird.

1. The common brown linnet, the *Fringilla linota* of Gmelin, well known to every one. These birds are much esteemed for their song: they feed on seeds of different kinds, which they peel before they eat: the seed of the *linum*, or flax, is their favourite food, whence the name of the linnet tribe. See **FRINGILLA Linota**.

2. The *linaria rubra major*, or greater red-headed linnet, or greater redpole; the *Fringilla camialina* of Linnæus. This has a fine red head, a grey neck, a dusky reddish brown back, and its breast and belly are somewhat reddish. The female of this species, however, has no redness in its head or breast, but has somewhat of a greenish cast on the brown of its back, and is yellowish on the breast, with some brownish spots. It is a common fraud in the bird-shops in London, when a male bird is distinguished from a female by a red breast, as in the case of this bird, to stain or paint the

feathers, so that the deceit is not easily discovered, without close inspection. This species of linnet is frequent on our sea-coasts, and is often taken in flight time near London. It is a familiar bird, and becomes cheerful in five minutes after it is caught.

3. The *linaria rubra minor*, or lesser red-headed linnet, or lesser redpole; the *Fringilla linaria* of Linnæus. This is the least of all the linnets, and on the back is of the same colour with the common linnet; the back part of its head is red, and also its breast, but the lower part of its belly is whitish. In this species, the female, as well as the male, has a red head, that of the male being ornamented with a rich shining spot of a purplish-red, and that of the female of a saffron colour; and both have their beaks much sharper, and their feet and legs blacker than in the larger kind. This is a gorgeous bird, whereas the larger species commonly flies single. This seems to be the species known about London by the name of stone redpole.

4. The last species is the *linaria montana*, or *Fringilla montana*, or mountain linnet. This is the largest of all the linnets, according to Willughby's description, though Mr. Pennant says that it is in size rather inferior to the common linnet. Its beak is very small; its head and back are of the same colour with those of the common linnet, and the feathers of its breast and belly are black, edged with white; the rump of the male is of a fine and beautiful red, and thus distinguishes it from the female. This species is common in Derbyshire, but seems not so frequent in other places. However, it is taken in the flight season near London with the linnets, and called a *white*. It breeds, according to Mr. Pennant, only in the northern parts of our island. Ray and Pennant.

It is remarkable of the linnet, that when it builds in hedges, and when in furze-bushes on heaths, in both which places the nests are very common, they are made of different materials. When they build in hedges, they use the slender filaments of the roots of trees, and the down of feathers and thistles; but when they build in heaths, they use moss, principally, for the outer part, finishing it within with such things as the place will afford, chiefly with wool and hair. These birds will have young ones three or four times a year, especially if they are taken away before they are able to leave the nests. They lay five whitish eggs, spotted like those of the gold-finch.

When they are intended to be taught to whistle tunes, or to imitate the notes of any other bird, they are to be taken from the old ones when they are not more than four days old; for at this time they have no idea of the notes of the old ones, and will readily be taught to modulate their voice like any thing that is most familiar to their ears, and within the compass of their throats. The honourable Mr. Barrington observes, that in order to be certain that a nestling will not have the call of its species, it should be taken from the nest when only a day or two old; though a bird of this age requires great trouble in breeding, and the chance is greatly against its being reared. There requires more care in the feeding them when they are taken thus young, than when they are left in the nest till nearly fledged, but they will be reared very well upon a food half bread and half rape-seed, boiled and braised: this must be given them several times a day. It must be made fresh every day, and given them sufficiently moist, but not in the extreme. If it be in the least sour, it gripes and kills them; and it too stiff, it is as mischievous, by binding them up.

They must be hung up as soon as taken from the nest, under the bird whose note they are intended to learn; or if they are to be taught to whistle tunes, it must be done by

giving them lessons at the time of feeding; for they will profit more while young in a few days, than in a long time afterwards, and will take in the whole method of their notes before they are able to crack hard seeds. Some have attempted to teach them to speak, in the manner of the parrot, or other birds, and they will arrive at some sort of perfection in it with great pains.

Mr. Barrington mentions a linnet, which being taken from its nest when only two or three days old, almost articulated the words *pretty boy*, as well as some other short sentences. See *SONG of Birds*.

LINNICK, in *Geography*, a town of France, in the department of the Roer, and chief place of a canton, in the district of Aix-la-Chapelle, seated on the Ruhr; five miles N.N.W. of Juliers. The place contains 2086, and the canton 13,589 inhabitants. N. lat. $50^{\circ} 57'$. E. long. $6^{\circ} 13'$.

LINOCARPUM, in *Botany*, so called by Micheli, Nov. Gen. 22. t. 21, from the resemblance of its fruit to that of *Linum*, Flax. See *RADIOLA* and *LINUM*.

LINOCIERA, a name given by Dr. Swartz, in honour of Geoffrey Linocier, a French physician, who flourished at the close of the sixteenth and beginning of the seventeenth centuries. He published at Paris in 1584 an account of the officinal aromatics of the East and West Indies. This book is accompanied by wooden cuts. Linocier also wrote upon the natural history of beasts, birds, fishes, and serpents; but on these subjects he borrowed largely from Gesner and other authors. The present genus was adopted by Schreber, from Swartz, who first called it *Thouinia*, in his *Prodromus*. Dr. Smith however suggests that *Linociera* may probably not be a distinct genus from *Chionanthus*, merely because they differ in the number of cells of the fruit: the former having two cells, the latter only one. But in some genera of this natural order, the number of cells in the ripe fruit has been discovered constantly to be fewer than in the young germen. In *Olea*, in particular, this was found to be regularly the case by the late M. Broussonet, though we know not that it had been before suspected. —Swartz Ind. Oce. v. 1. 49. Schreb. 784. Willd. Sp. Pl. v. 1. 154. (*Thouinia*; Swartz Prod. 14.) — Clafs and order, *Diandria Monogynia*. Nat. Ord. *Scitagineae*, Linn. *Jasminaceae*, Juss.

Gen. Ch. Cal. Perianth inferior, very small, four-toothed, obtuse, permanent. Cor. Petals four, equal, linear, channelled, erect, spreading at the top, considerably longer than the calyx. Stam. Filaments two, very short and broadish; anthers linear, two furrowed, the length of the corolla, erect, each adhering slightly to one side of two of the petals. Pist. Germen superior, ovate, quadrangular; style short; stigma oblong, cloven. Peric. Berry, or rather Drupa, ovate, acuminate, of two cells. Seeds solitary, oblong.

Eff. Ch. Calyx four-toothed. Corolla of four petals, the two opposite ones connected at their base by the anthers. Fruit of two cells and two seeds.

L. ligustrina is the only species described by Swartz. It is a native of dry open places in the West Indies, especially Jamaica and St. Domingo, flowering in June and July.

LINONASME, the name of a melancholy and solemn air of the ancient Greeks, on the death of Linus.

LINOS is supposed to imply the same air. Rousseau, however, calls it a kind of rustic song among the ancient Greeks; they had likewise a funeral song of the same name, which answered to what the Romans called *Nenia*. Some

say that the Linos was invented in Egypt; while others ascribe its invention to Linus, the Euboran.

LINOSA, in *Geography*, a small island in the Mediterranean, not far from the coast of Tunis, near the island of Lampedusa.

LINOTA, in *Ornithology*. See LINNET, and FRINGILLA *Linota*.

LINOZOSTIS, in *Botany*, a name given by the ancient Greek writers to two plants very different from one another; the one is the *mercurialis*, or English mercury, a plant common in uncultivated places, and eaten by many boiled in manner of asparagus; the other the *epilinum*, or dodder, growing upon the plants of flax.

Theophrastus, Dioscorides, and the ancient Greeks, use the word in the first sense, and the modern Greeks in the latter.

The Latin authors call this *linozostis*, or *epilinum*, sometimes *anginalis*, and *podagra lini*, looking on it as a disease which chokes the plant it grows on, and causes gouty tumours on the stalks. See DODDER.

LINQUES, in *Geography*, a country of Celebes, lying between the two states of Binano and Bankale, not far from the bay of *Touratea*; which see.

LINSCHOTTEN, a town of Holland; eight miles W. of Utrecht.

LINSDDRF, a town of Bohemia, in the circle of Koeniginratz; 32 miles E.S.E. of Geverberg.

LINSE, a town of Prussia, in Oberland; 15 miles S.E. of Marienwerder.

LINSEED, or LINE-SEED, a sort of grain, being the seeds of the common flax, (which see,) which enters the composition of several medicines, and yields, by expression, an oil, that has most of the qualities of nut oil, and is according generally used, in lieu thereof, in painting, and for burning.

Those who manufacture it in large quantities have mills turned by horses or water, for the more expeditious dispatch of their work. See OIL.

LINSEED, in the *Materia Medica*. These seeds have an unctuous mucilaginous sweetish taste, without any remarkable smell. The oil which they yield in expression, when carefully drawn without the application of heat, has no particular taste or flavour; and in some properties differs considerably from most other oils of this kind; as congealing in water, not forming a solid soap with fixed alkaline salts, acting more powerfully as a menstruum on sulphurous bodies, than any other expressed oil that has been tried.

The seeds, boiled in water, yield a large proportion of a strong flavourless mucilage; but to rectified spirit they give out little or nothing. These seeds have been sometimes used, in a season of scarcity, instead of grain; but they appear to be an unwholesome as well as an unpalatable food. They afford little nourishment, impair the stomach, and produce great flatulence, as Galen long ago observed. Tragus relates, that those who fed upon them in Zealand, had the hypochondres in a short time distended, and the face and other parts swelled; and that not a few died of these complaints.

Infusions and decoctions of these seeds, like other vegetable mucilages, are used as emollients or demulcents in hoarsenesses, coughs, and pleuritic symptoms, which frequently prevail in catarrhal affections; they are also recommended in nephritic pains and stranguries; a spoonful of the seeds unbruited is said, for these purposes, to be sufficient for a quart of water. The seeds are also much used externally in emollient and maturating cataplasms. The seeds from which the oil has been expressed, boiled in milk, and applied warm, on a cloth, to hernia, are much recommended in

in the Satyr. Silefiac. Specim. 4. Obf. 4. The expressed oil is an officinal preparation, and is said to be of a more healing and balsamic nature than the other oils of this class; it has therefore been very generally employed in pulmonary complaints; also in colics, and constipations of the bowels. It is used in common with other oils as a vernifuge. Lewis Mat. Med. Woody. Med. Bot.

LINSEED Cakes, in *Agriculture*, the name of such cakes as remain after the expression of the oil from flax seed. They are at present much used in the fattening of cattle, sheep, and other sorts of live stock, and of course of great value and importance to the farmer. The price however has been of late so high as to greatly lessen the demand for this article. See OIL-CAKE.

LINSEED, *Infusion of*. See INFUSION.

LINSELLES, in *Geography*, a town of France, in the department of the North; five miles N. of Lille.

LINSENBAHRT, or as he is called in his works in Latin, **LENTILIUS, ROSINUS**, in *Biography*, a physician, was born at Waldenburg, in the province of Hohenlohe, in February 1657. He commenced his studies at Heidelberg at the age of fourteen, and thence removed to Jena in 1673. But his scanty means of subsistence compelled him the next year to engage as a teacher in the vicinity of Leipzig, where he continued till 1677. He then travelled, with a view to improve his situation, through several of the principal towns in the north of Germany, and settled at Mittau, in Courland, in the same capacity of teacher. To aid this feeble resource, Linsenbahr began likewise to practise medicine, in which his success was such, that the marquis of Anspach appointed him physician to the town of Creilheim, in Franconia; whither he repaired in 1680, after having been admitted a licentiate in medicine at Altdorf. He afterwards settled at Stutgard, and was patronised by the marquis of Dourlach; and, when that prince was driven by the war to take refuge at Basle, he was nominated honorary physician to the duke of Wirtemberg, and became his first physician in 1711. He accompanied the son of this prince in his travels, during three years; and after his return, in 1716, remained in the tranquil exercise of his profession until his death, in February 1733. Linsenbahr was ardent in his attention to the qualities and operations of drugs during his whole life, regarding that species of knowledge as the most important to the physician, and being somewhat too negligent of the study of anatomy, and of the writings of the ancients. He was the first who recommended the use of arsenic internally, for the cure of intermittent fevers, in which its efficacy has been established by recent observers, and especially by Dr. Fowler, of York. He was a decided enemy to blood-letting, which he strenuously endeavoured to discard from the practice of medicine; and particularly condemned the custom, then prevalent among the Germans, of letting blood at the equinoctial periods, against which he published a treatise in his mother-tongue, at Ulm, in 1692. He was likewise author of the following works. "Tabula Consultatoria Medica" Ulm, 1696. "Miscellanea Medico-Practica tripartita," ibidem, 1694. "De Hydropothæ causâ et cura, Dissertatio," ibid. 1770. "Eteodromus Medico-Practicus anni 1709," Stutgard, 1711. "Jatromemata Theoretico-Practica," ibid. 1712. Eloy Dict. Hist. de la Méd.

LINSPINS, or **LINCHPINS**, are small pins of iron, which keep the wheel of a cannon, or waggon, on the axle-tree; for when the end of the axle-tree is put through the nave, the linspin is put in to keep the wheel from falling off.

LINSTOCK, a short staff of wood, about three feet

long, having at one end a piece of iron divided into two branches, each of which has a notch to hold a piece of match, and a screw to fasten it there; the other end being also shod with iron, and pointed to flick into the ground, or in the deck when it is used at sea. It is used by the gunners in firing cannon. It is frequently used in small vessels, in an engagement, where there is commonly one fixed between every two guns, by which the match is always kept dry and ready for firing.

LINSTORP, in *Geography*, a town of Sweden, in the province of Medelpedia; 16 miles N. of Sundswal.

LINT, in *Surgery*, is the scraping of fine linen, used by surgeons in dressing wounds. It is made into various forms, which acquire different names, according to the difference of their figures.

Lint made up in an oval, or orbicular form, is called a *pldgit*; if in a cylindrical form, or in the shape of a date olive-stone, it is called a *dyffil*.

These different forms of lint are required for many purposes; as, 1. To stop blood in fresh wounds, by filling them up with dry lint before the application of a bandage; though if scraped lint be not at hand, a piece of fine linen may be torn into small rags, and applied in the same manner. In very large hemorrhages the lint, or rags, should be first dipt in some styptic liquor, alcohol, or oil of turpentine, or sprinkled with a styptic powder. 2. To agglutinate and heal wounds; to which end lint is very serviceable, if spread with some digestive ointment, or balsam, or dipt in some vulnerary liquor. 3. In drying up wounds and ulcers, and forwarding the formation of a cicatrix. 4. In keeping the lips of wounds at a proper distance, that they may not hastily unite, before the bottom is well digested and healed. 5. They are highly necessary to preserve wounds from the injuries of the air. Small portions of lint tied round with thread are chiefly used in dressing wounds and ulcers of the deeper kind. They are always applied to the bottom of such wounds, the remaining cavity being filled up with other portions of lint. By this means, the immediate removal of the dressings is not only provided for, but the possibility of leaving any part of them in the bottom of the wound is prevented.

In very large wounds, and especially in amputations of the limbs, which operations are frequently required in the army and navy, at times when lint is very scarce, it will be very sufficient to dress the bare bone and face of the wound with scraped lint, filling up the cavity with tow, and covering all with a large compress.

Surgeons of former ages formed compresses of sponge, feathers, wool, or cotton, linen being scarce; but lint is far preferable to all these, and is at present universally used.

LINTCIN, in *Geography*, a city of China, of the second rank, in Chan-tong, on the grand canal, much frequented by vessels as a magazine for all sorts of merchandise. N. lat. 36 56'. E. long. 115 31'.

LINFEL, in *Architecture*, the piece of timber which lies horizontally over door-posts and window-jambes; as well to bear the thickness of the wall over it, as to bind the sides of the walls together.

LINTELN, in *Geography*, a town of Germany, in the county of Verden; four miles N.E. of Verden.

LINTERNUM, or **LITERNUM**, in *Antient Geography*. See LITERNUM.

LINTHAL, in *Geography*, a town of Switzerland, in the canton of Glaris; 12 miles S.W. of Glaris.

LINTIN, a town of China, of the second rank, on a small island in the province of Quang-tong; 15 miles N.E. of Macao.

LINTNER,

LINTNER, in *Biography*, an excellent performer on the German flute at Berlin, in 1772, a disciple of the late Frederic II. king of Prussia's flute-master, Quantz.

LINTON, in *Geography*, a small market town in the hundred of Chilford. Cambridgeshire, England, is situated ten miles from Cambridge, and forty-six from London. The town consists of several irregular streets, the chief of which is about half a mile in length; the houses are principally low and covered with thatch; some however are of brick, and neatly built. The church is a spacious structure, and built with flints, intermixed with stone and plaster. It consists of two aisles, a nave, a chancel, and a large tower. It contains several monuments and sepulchral memorials, among which is a handsome mural monument by Wilton, to the memory of Mrs. Elizabeth Bacon, and her brother Peter Sandley, esq. A Sunday school was recently established in this town by the exertions of the Rev. Mr. Fisher, the vicar; it now affords tuition to upwards of an hundred children. A market, principally for corn, is held on Thursdays; it was originally on Tuesdays, and was granted in the year 1245, with an annual fair for three days. The fair has been discontinued, but two others have been established; one for sheep, and one principally for hiring harvest men. In the reign of Edward III. there was an alien priory at Linton, subordinate to the abbey of St. Jacutus de Insula in Britany; being seized for the king in the reign of Henry V., it was given by his successor to the master and fellows of Pembroke hall, Cambridge. At Barham also, in this parish, was a priory of Crutched Friars, so early as the year 1292; the site was granted by Henry VIII. to Philip Parth, esq. and afterwards to John Millicent, esq. who was before possessed of the manor. In the Millicents the priory and manor continued till the year 1740, when John Millicent, esq. the last of the family, died; his widow, afterwards married to the Rev. C. Lonsdale, left her estates to the master and fellows of Pembroke hall. Barham hall, Mrs. Lonsdale's seat, appears to have been formed out of the conventual buildings: the hall, chapel, and cloisters, still remain: it was appropriated, by Mrs. Lonsdale's will, as a country seat for the master of Pembroke hall for the time being. In the population return to parliament in the year 1801, the parish of Linton was stated to contain 183 houses, and 1157 inhabitants. Lysons' *Magna Britannia*, vol. ii. *Beauties of England and Wales*, vol. ii.

LINTZ, a town and citadel of Germany, surrounded with an old wall, and situated on the E. side of the Rhine, containing about 600 houses; 10 miles S.E. of Bonn. N. lat. 50° 34'. E. long. 7° 14'.—Also, a well-built and populous town of Austria, seated on the Danube; consisting of a single street, with some annexed suburbs, in which is the sovereign's citadel, situated on an eminence, commanding a fine prospect. The trade of the town is considerable, and it has fairs that possess privileges under proper regulations, at Easter and St. Bartholomew's; 30 miles S.E. of Passau. N. lat. 48° 18'. E. long. 14° 15'.

LINTZENEGG, a town of Austria; 10 miles S. of Zwettl.

LINUFAR, in *Botany*, a name used by some of the writers of the middle ages, to express the water-lily. The Arabians gave this genus of plants the name of *nilufar*, and this word *linufar* is only formed of that, by transposing some of the letters.

LINUM, in *Botany*, the *lino* of Dioscorides, Theophrastus, and other ancient Greek authors, appears to be derived from *lino*, to hold, the fibres of this plant being so remarkable for their tenacity, that its herbage has always been in the greatest estimation for the manufacture of linen

cloth, whilst its seeds by pressure afford a valuable oil. (See FLAX.)—Linn. Gen. 113. Schreb. 206. Willd. Sp. Pl. v. 1. 1533. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 342. Prod. Fl. Græc. v. 1. 214. Ant. Hort. Kew. ed. 2. v. 2. 184. Tournet. t. 176. Juss. 303. Lamarek Illustr. t. 210. Gærtn. t. 112.—Class and order, *Pentandria Pentagynia*. Nat. Ord. *Gruinales*, Linn. *Caryophyllaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five leaves, lanceolate, erect, small, permanent. *Cor.* funnel-shaped; petals five, oblong, gradually broader towards the upper part, obtuse, much spreading, large. *Stam.* Filaments five, awl-shaped, erect, the length of the calyx; (also five rudiments alternating with them) anthers simple, arrow-shaped. *Pist.* Germen superior, ovate; styles five, thread-shaped, erect, as long as the stamens; stigmas simple, reflexed. *Peric.* Capsule globose, bluntly five-sided, of ten cells and ten valves. *Seeds* solitary, ovate or flattish, acuminate, smooth.

Ess. Ch. Calyx five-leaved. Petals five. Capsule superior, with ten valves and ten cells. Seeds solitary.

In the 14th edition of Linnæus's *Système Vegetabilium* we meet with twenty-two species of *Linum*. Willdenow has twenty-nine, besides which, four, not mentioned by him, occur in the *Horius Kewensis*, and one in the *Prodromus Floræ Græcæ*. But from the list is to be deducted *L. Radiola* which is the *Radiola millegrana* of Dr. Smith's *Flora Britannica*, 202.—The genus is divided into two sections, the first having alternate, the second opposite, leaves.—Examples of the first section are

L. usitatissimum Common Flax. Linn. Sp. Pl. 397. Engl. Bot. t. 1357. Curt. Lond. fasc. 5. t. 22.—Calyx-leaves ovate, acute, three-nerved. Petals crenate. Leaves lanceolate, alternate. Stem mostly solitary.—Not infrequent in fields throughout the more temperate parts of Europe, in consequence probably of its being a plant of such general cultivation, flowering in July. Root annual, fibrous, small. Stem erect, round, smooth, leafy. Leaves entire, three-nerved, smooth. Flowers on stalks, erect, of a sky-blue colour. Seeds elliptical, very shining. For the uses and management of this valuable plant, we need not repeat what is already given under the article FLAX.

L. trigynum Three-styled golden Flax. Sm. Exot. Bot. t. 17. Ant. Hort. Kew. ed. 2. n. 3. Curt. Mag. t. 1100.—Leaves alternate, elliptical, ferrated, acute. Styles three. Capsule of six cells.—A native of the East Indies, where it was gathered by colonel Hardwicke on the sides of mountains flowering in December. The natives call it *Gul Astarfe*, from its fine golden hue, *Gul* signifying a flower, and *Astarfe* a coin of the same metal current in India, of the value of 2l. sterling.—Stem shrubby. Branches round and leafy. Leaves smooth, dark green, pointed, on a short footstalk. Flowers large and handsome, nearly odororous.

L. hispidum Hairy Flax. Linn. Sp. Pl. 398. Willd. n. 4. Jacq. Austr. t. 31.—Calyx hirtute, acuminate. Flowers sessile, alternate. Leaves on the branches opposite.—A native of Austria and Hungary, flowering in June and July. Root perennial, woody. Stems from a foot and a half to two feet in height, branching towards the top. Leaves lanceolate or ovate, hairy at their edges and on their backs, sometimes nearly smooth. Flowers blue; the petals so closely united at the base as to resemble a monodeltous, funnel-shaped flower. Linnæus remarks that this is very closely allied to *L. neoliflorum*.

L. byrriciflorum Mallow-flowered Flax. Curt. Mag. t. 1048,

1748, approaches very nearly to *L. hirsutum*. Its flowers however are larger, and of a red lili or purplish tinge.

L. arboreum. Tree Flax. Linn. Sp. Pl. 400. Curt. Mag. t. 234.—Leaves wedge-shaped. Stems arboreous t.—A native of the Levant, from whence it was sent to England by Dr. Sibthorp in the year 1788. It flowers from May to August. This beautiful species is an arboreous shrub, rising to the height of several feet. Stems rather slender, leafy. Leaves on short footstalks, the upper ones slightly embracing the stem, of a glaucous colour.

The two following species come under the other section of this genus, from having opposite leaves.

L. catharticum. Purging Flax. Mill-mountain. Linn. Sp. Pl. 401. Engl. Bot. t. 382. Curt. Lond. fasc. 3. t. 19. Fl. Dan. t. 851.—Leaves opposite, obovato-lanceolate. Stem forked. Petals pointed.—Not uncommon in elevated, dry pastures in all parts of Great Britain, bearing flowers from June to August.—Root annual, small. Stems leafy, erect, many-flowered. Leaves obtuse, entire. Flowers small, white, pendulous before they expand.—Dr. Smith observes, in the *Flora Britannica*, that *L. catharticum* is very nearly allied to *Geranium*, for that its stamens are sometimes monadelphous. The whole herb is smooth, bitter, and has long been celebrated for its purgative qualities.

L. quadrifolium. Four-leaved Flax. Linn. Sp. Pl. 402. Curt. Mag. t. 431.—Leaves four in a whorl.—A native of the Cape of Good Hope, flowering in May and June. Root thick and woody. Stems numerous, about six inches in height, forked, slender, upright. Leaves four in a whorl. Flowers yellow.

This is the original *quadrifolium* of Linnæus, that of Ray having blue flowers.

LINUM, in Gardening, comprehends plants of the herbaceous, annual, and perennial shrubby kinds, of which the species are the common flax (*L. usitatissimum*); the perennial flax (*L. perenne*); the shrubby flax (*L. suffruticosum*); the tree flax (*L. arboreum*); and the African flax (*L. Africanum*.)

In the second sort there is a variety which is procumbent, with smaller flowers.

Method of Culture.—All these plants may be increased by seeds, layers, and cuttings.

But the two first sorts are best raised by sowing the seeds in the early spring months, as March, or the following month, the former in fields or plantation-grounds, where the soil is fresh, good, and well reduced into order, by frequent digging over, or ploughing and harrowing, in narrow drills, or broadcast, and raked or harrowed in with a light harrow; the plants being afterwards kept perfectly clean from weeds by repeated hoeings.

About the end of August, when the plants have attained their full growth, and begin to turn yellow at bottom, and brown at top, and their seeds to ripen, it is proper time to pull them; though, if it were not for the sake of the seed, they might be pulled a little before the seeds ripen, by which the flax is generally better coloured and finer; but if suffered to stand till the seeds are fully ripe, it is commonly stronger, somewhat coarser, and more in quantity. It should be pulled up by handfuls, roots and all, shaking off all the mould; then either spreading them on the ground by handfuls, or binding them in small bunches, and setting them upright against one another, for ten days or a fortnight, till they are perfectly dry, and the seed fully hardened, then housed, and the seed thrashed out, cleaned, and placed in a dry airy situation, being afterwards put up for use. The flax, after being rippled and sorted, should be carried to a pond of nearly stagnant water, being placed in it with the

bundles crossing each other in different directions, so as to keep the whole in a close compact state, being kept just below the surface of the water, by proper weights applied upon it. It should remain in this sleep till the stems become brittle and the bark readily separates, when it must be taken out and spread thinly on a flint pasture, being occasionally turned until it becomes perfectly bleached and dry, when it is in a proper state for the purpose of being converted into flax by the huckler.

With regard to the latter, or perennial sort, it should be sown in a bed or border of good earth, in shallow drills at the distance of six inches; and when the plants are two or three inches in height, they should be thinned to the same distances, and in autumn be planted out in the places where they are to grow. But it is probably a better practice to sow them at once in the places where they are to grow, thinning them out properly afterwards.

The three other sorts may be best increased by planting cuttings of the branches in pots of light fresh earth, plunging them in the tan hot-bed, or by layers laid down in the latter summer months. When the plants in either mode have stricken good root, they may be removed into separate pots, and be managed as other tender exotic plants, that require the protection of the green-house. And they may likewise be raised from seeds when they can be procured, which should be sown in pots, and placed in a hot-bed in the spring season.

The first sort may be said to be one of the most valuable plants in the whole vegetable kingdom; as from the bark of its stalks is manufactured flax or lint, for making all sorts of linen cloth; from the cloth, when worn to rags, is made paper; and from the seeds of the plant linseed oil is expressed, which is much used by painters, and in other arts; and the refuse, after expression, forms the oil-cakes so valuable in the fattening of cattle, sheep, and other sorts of live stock.

A few plants of this, and the second sort, may be introduced in the clumps and borders of the pleasure-ground; and the three other sorts afford variety in green-house collections among other potted plants.

LINUM *Carpasium*, *Carpasian flax*, or *linen*, a term often occurring in the old writers, and used by different authors in very different senses.

The first use we find made of the word, is for the expressing a kind of flax which was finer and smaller, as well as brighter and more glossy, than any other. Pliny uses the word in this sense, and tells us, that such flax was principally brought from Spain; and that both it, and the linen made of it, were, in his time, called by the name *carpasian*: from this it became a custom to call all very fine flax, or fine linen, *carpasian linen*, and the word signified no more than delicate, or fine.

The modern Greeks use the word in this sense, and Suidas expresses the finest linen veils by the term *carpasian*. The author of the *Periplus Maris Erythræi*, who was contemporary with Pliny, calls the flax, of which the Indian linens were made, *carpasia*; but none of the older Greeks have the word. This author is not, however, to be appealed to for ascertaining the purity of the language of the ancients; for it is plain that he has taken in many words which are not good Greek, nor ever were used by any author of credit, but are the mere technical terms of the tradesmen and merchants of that time.

Pausanias uses the word *carpasium linum* in a very different sense from all these; for with him it is made to express the flax made of the stone asbellos, and the linen made of this, which was thrown into the fire to be cleaned. Solinus uses

the word also in the same sense: he says, that in Carystos there was found that kind of flax which remained unhurt in the fire; and Hieronymus Mercurialis thinks that the *carbysis* of the ancient Romans was a word properly used only to signify the carpathian flax of Pausanias, which was not to be destroyed by the fire, and was the true *linum incombustibile*, or threads of the asbestos stone, or linen made of that material. This, however, is not the sense of the word in later times, for we find it evidently used for all linen manufactures of whatever kind.

LINUM, Carystium, in *Natural History*, a name given by Pausanias to the asbestos. It was found plentifully in this author's time, near Carystos, a town in the Negropont, and thence obtained its name.

LINUM Catharticum, Purging flax, in *Medicine*, makes a common purge among the country people. It is almost as rough as that of *gratiola*.

It is a species of wild flax, distinguished by the name of meadow flax, with small flowers which appear in July, and commonly called mountain-flax, growing without culture on chalky hills and dry pasture grounds in many parts of England, and is taken in infusion in ale.

This herb is said to be an effectual and safe cathartic; an infusion of a handful of the fresh leaves in whey or white wine, or a drachm of the leaves in substance with a little cream of tartar and aniseeds, is directed for a dose. Linnæus recommends an infusion of two drachms of the dry leaves as a mild laxative.

It is greatly recommended by some in dropsies, and to prevent its griping they mix anise or some other of the carminative seeds with it. It is given in most chronic cases, where people's constitutions are strong enough to bear it, and often with great success.

LINUM Vivum, or incombustibile, cloth made of a sessile, stony substance, of a whitish colour, and woolly texture, separable into threads, or filaments, which will endure the fire without consuming. See *AMIANTHUS* and *ASBESTUS*.

As to the art of managing this mineral, and of spinning and weaving it, &c. the accounts we have are various.

Marco Polo, the Venetian, gives us the manufacture of the linum, found in the province of Chinchintheles, in Tartary, from one Curfica, a Turk, superintendent of the mines of that country, as follows. The lanuginous mineral, being first dried in the sun, is then pounded in a brass mortar, and the earthy part separated from the woolly, which is afterwards well separated from filth; being thus purged, it is spun into thread, like other wool, and afterwards woven into cloth, which, if foul or spotted, they cleanse, he says, by throwing it into the fire for an hour's time, whence it comes out unhurt, as white as snow: which very method, according to the account given us by Strabo, seems to have been used, in ordering the Cretan amianthus; with this addition, that after it was pounded, and the earthy part separated from the woolly, he says it was combed; and so does Agricola.

Signior Ciampani, after describing four sorts of the linum, whereof he had specimens in his museum; the first sent him from Corfu, the second from Sestri di Ponente, the third coarser and darker than the rest, and the fourth from the Pyreneans; and after observing, that though he kept it three weeks in a glass-house fire, yet he found it unaltered, though it could not preserve a stick wrapped in it, from the fire; he proceeds to shew the manner of spinning, and making it into cloth, which he effected thus:—He first laid the stone in water, if warm the better, for some time to soak; then opened and divided it with his hands, that the earthy parts might fall out of it, which are whitish

like chalk, and serve to bind the thready parts together. This makes the water thick and milky. That operation he repeated six or seven times, with fresh water, opening and squeezing it again and again, till all the heterogeneous parts were washed out, and then the flax-like parts were collected, and laid in a sieve to dry. As to the spinning, he first shews a method discovered to him, which is thus:—Lay the linum, cleansed as before, between two cards, such as they card wool with, where let it be gently carded, and then clapped in between the cards, so that some of it may hang out of the sides; then lay the cards flat on a table, or bench; take a small reel, made with a little hook at the end, and a part to turn it by, so that it may be easily turned round; this reel must be wound over with white thread; then, having a small vessel of oil ready, with which the fore finger and thumb are constantly to be kept wet, both to preserve the skin from the corrosive quality of the stone, and to render the filaments thereof more soft and pliant, by continuing to twist about the thread on the reel in the asbestos hanging out of the cards, some of the latter will be worked up together in it; and, by little and little, the thread may, with care, be woven into a coarse sort of cloth; and, by putting it into the fire, the thread and oil will be burnt away, and the incombustible cloth remain.

But finding this way, of uniting the stone with the thread, very tedious; instead of the thread, he put some flax on a distaff, and, by taking three or four filaments of the asbestos, and mixing them with the flax, he found they might be easily twitted together, and the thread thus made much more durable and strong; so that there is no need of carding, which rather breaks the filaments, than does any good: only open and separate the filaments, after washing, on a table, and take them up with the flax, which is sufficient.

As to the making of paper, he says, in the washing of the stone there will remain several short pieces in the bottom of the water, of which paper may be made in the common method. He concludes with the best way of preserving the cloth, or any thing made of the linen, which, by reason of its excessive dryness, is very apt to break, and twist; and it consists in keeping it always well oiled, which is the only preservative. When the cloth is put in the fire, the oil burns off, and the cloth comes out white and purified.

LINUM, in *Ancient Geography*, a country of Asia Minor, in the province of Hellepont, between Parium and Priæ. —Also, a promontory of Illyria, in Chaonia.

LINUS, in *Biography*, supposed to be the first bishop of Rome, was born at Volterra, in Tuscany. According to Irenæus he received his bishopric from the hands of the apostles Peter and Paul, which he is supposed to have retained twelve years. He is mentioned by St. Paul in the second epistle to Timothy, and is said, by some writers, to have been the son of Claudia, who is mentioned at the same time. Nothing more is known of him which can be relied on, though it has been said that he testified to the truth of his principles by suffering martyrdom; and two letters in the second volume of the Biblioth. Patr. have been ascribed to him, but there is no good authority for these facts. See Lardner, vol. ii. edit. 1788.

LINUS. This personage and Orpheus seem to have been the most ancient poets and musicians of Greece; but to determine whether Linus was the master of Orpheus, or Orpheus of Linus, would be as vain to attempt, as difficult to accomplish. All that can be done at this distance of time, is to compare the opinions of ancient writers upon the subject, and to incline to the most numerous and re-

spectable evidence: and in pursuing this method, it appears that the majority are in favour of the superior antiquity of Linus. No testimony places him in a more remote period, or does more honour to his memory, than that of Herodotus; who tells us (Euterp.) "that among other memorable customs, the Egyptians sing the song of Linus, like that which is sung by the Phœnicians, Cyprians, and other nations, who vary the name according to the different languages they speak. But the person they honour in this song, is evidently the same that the Grecians celebrate: and as I confess my surprize at many things I found among the Egyptians, so I more particularly wonder whence they had this knowledge of Linus, because they seem to have celebrated him from time immemorial. The Egyptians call him by the name of *Mineros*, and say he was the only son of the first of their kings, but dying an untimely death, in the flower of his age, he is lamented by the Egyptians in this mourning song, which is the only composition of the kind used in Egypt."

According to archbishop Usher, Linus flourished about 1280 years before Christ, and he is mentioned by Eusebius (Præp. Evang.) among the poets who wrote before the time of Moses. Diodorus Siculus, who is very diffuse in his account of Linus (lib. iii. cap. 85.) tells us from Dionysius of Mitylene the historian, who was contemporary with Cicero, that Linus was the first among the Greeks who invented verse and music, as Cadmus first taught them the use of letters. The same writer likewise attributes to him an account of the exploits of the first Bacchus, and a treatise upon Greek mythology, written in Pelasgian characters, which were also those used by Orpheus, and by Pronapides, the preceptor of Homer. Diodorus says, likewise, that he added the string *lichanos* to the Mercurian lyre, and gives to him the invention of rhythm and melody, which Snidas, who regards him as the most ancient of lyric poets, confirms. He is said by many ancient writers to have had several disciples of great renown, among whom were Hercules, Thamyris, and, according to some, Orpheus.

Hercules, says Diodorus, in learning of Linus to play upon the lyre, being extremely dull and obstinate, provoked his master to strike him, which so enraged the young hero, that instantly seizing the lyre of the musician, he beat out his brains with his own instrument. Heroes are generally impatient of controul, and not often gifted with a taste for refined pleasures; hence, relying merely on corporal force, their mental faculties, feeble perhaps by nature, are seldom fortified by education.

With respect to the dirges, which Plutarch, from Heracles of Pontus, mentions as written by Linus, we find no account of them in any other ancient author. It appears, however, that his death has given birth to many songs of that kind, which have been composed in honour of his memory. A festival was likewise instituted by the name of *Linia*, for the celebration of his virtues; and so numerous were his inventions, and various the periods and places in which different authors fix them, that some have tried to reconcile these jarring accounts, by supposing that there were three several illustrious personages of that name; a supposition which we shall not pretend either to affirm or deny.

"The Thebans, says Pausanias (in Bæotic.) assure us, that Linus was buried in their city; and that Philip, the son of Amyntas, after the battle of Cheronæa, which was fatal to the Greeks, excited by a dream, removed his bones into Macedon, whence, by counsel received in another dream, he sent them back to Thebes; but time has so defaced his tomb, that it is no longer discoverable."

Homer (lib. xviii. ver. 569.) has paid a tribute to the memory of Linus, in his description of the shield of Achilles.

"To these a youth awakes the warbling strings,
Whose tender lay the fate of Linus sings;
In measure'd dance behind him move the train,
Tune soft the voice, and answer to the strain."

Pope, in his note on this passage, says, from Pausanias, that "before the yearly sacrifice to the muses on mount Helicon, the obsequies of Linus were performed, who had a statue and altar erected to him in that place. Homer alludes to that custom in this passage, and was doubtless fond of paying this respect to the old father of poetry."

LIO, in *Geography*, a lake of Thibet, about 30 miles in circumference. N. lat. 31° 22'. E. long. 86° 34'.

LIOI-KIA-LANC-TSA, a town of Thibet, 100 miles S.S.E. of Lassa. N. lat. 28° 8'. E. long. 92° 44'.

LIOIPOU, a lake of Thibet, about 30 miles in circumference. N. lat. 34° 27'. E. long. 90° 34'.

LION, LEO, in the Linnæan system of *Zoology*, is a species of quadrupeds belonging to the *felis* or cat kind, with a long tail and pale-red or tawny body. See *FELIS*.

The lion is an inhabitant of all parts of Africa, and the hot parts of Asia, such as India and Persia, and some few are found in the deserts between Bagdat and Bassorah, on the banks of the Euphrates; but they most abound in the torrid zone, where the size is the largest, and their rage most tremendous, being inflamed by the influence of a burning sun and a very dry soil. It is observed, that, though they reign absolute masters over every beast, their rage diminishes and their timidity increases as they approach the habitation of the human race. They have been also known to spare the weaker animals, and many instances are related by A. Gellius, Ælian, and Pliny, &c. of their gratitude. Lions are capable of being tamed; and the monarch of Persia is said, on days of audience, to have two large lions chained on each side of the passage to the room of state, led there by keepers in chains of gold. The lion preys on all kinds of animals; having roused them into view by his roar, he starts on his prey, striking it with his talons, and tearing it to pieces. He also invades the folds, leaping over the fences with his prey, and his strength is so great, that he can carry off a middling ox with the utmost ease. He sometimes seizes his prey by surprize, and mankind falls a victim to his hunger, more through necessity, as it is said, than choice. The Arabs have a notion of his sparing the tender sex, but Dr. Shaw informs us in his *Travels*, p. 244, that the lion observes no distinction in these days. The flesh is often eaten in Barbary, and is said to resemble veal in taste. Pennant's *Brit. Zool.* p. 165, &c.

LION-Monkey. See *SIMIA Oedipus*.

LION, Seal. See *PHOCA Leonina*.

LION-PUCERON, in *Natural History*, the name given by Mr. Reaumur to a genus of worms which destroy the pucerons in the same manner that the formica leo does the *ants*.

These little insects are a prey also to a sort of worm hatched from the egg of a two-winged fly. This has no legs, and is of several colours. See *VER-PUCERON*.

Though these lion-pucerons be all hexapodes, yet they are of different origin; some being produced from the eggs of a four-winged fly, others from those of a beetle. As the formica leo has two horns, the extremities of which serve him by way of mouths, our lion-puceron has the same kind also; but as the former of these insects can only move backwards, and is forced to make snares for his prey, not being able to hunt it, this creature runs very nimbly in the com-

iron way, and seizes its prey, without having recourse to such stratagems.

The body of the lion-puceron is longer than that of the formica leo, and is flat; the breast is the thickest and broadest part of it, and from this it gradually tapers off to a point at the tail; it has two legs fixed to the breast, the other four to the anterior rings of the body; and when it moves, the posterior end of the body serves it in the place of a seventh leg, for it always bends it downward, and draws it along the surface it walks upon. The back of this creature is not smooth or glossy, but is every where rough, and full of wrinkles, and seems as if every ring of it was composed of several other smaller rings.

This is the general description of the creature, treating of it in the general way, these characters suiting all the kinds of it. There are others, however, by which the whole class may be divided into three principal kinds.

These are much more voracious devourers of the pucerons, than the worms which feed on them. A small puceron, seized by one of them, is eaten in an instant, and the very largest is not the work of half a minute for them.

These creatures are very small when first produced from the egg, and yet they immediately begin to feed. They are so ravenous of food also, that whenever they can they catch and eat one another. But as the pucerons, among which they live, are easier to be caught, they usually escape one another's fury pretty well; unless where there is a scarcity of the pucerons, or when they offend one another.

It is easy to conceive that a creature, which feeds so very fast, must soon arrive at its full growth; and this is the case with these animals, for within five or six days of their being hatched from the egg, they are ready for their final transformation, or the putting on the form of the animals to whose eggs they owed their origin. In order to this, the creature leaves the place where he has hitherto fed, and seeks the folds of a leaf, or some other such convenient receptacle, where it spins a web of very fine silk, every way surrounding its body with it, and under this cover passes the state of a nymph or chrysalis. The silk of this web is not only very strong, but the threads are very closely laid together, so that it is much firmer than the webs of any of the caterpillar kind. It is of a roundish figure, and is somewhat smaller than a pea.

This round figure is owing to the form into which they roll up their body, which serves as a mould for it; and the orifice, out of which the silky matter is produced, is at the extremity of the posterior part of the body. The creature continues in this state about three weeks, if it be in the beginning of summer that it goes into it; but if toward autumn, it remains in it all the following winter; and is afterwards, in spring, seen to come out in the form of a very beautiful fly, of a remarkable large size, in proportion to the creature it is produced from, and the web out of which it comes. It is a very long-bodied one, and much resembles the libella or dragon-fly, only that its wings are larger in proportion to its body: these wings are of a most delicately fine structure, the finest gawse being coarse and thick in comparison to them. These, when the creature is at rest, are placed in an angle over the body, and form a sort of canopy or tent for it; but they are so perfectly transparent, that the body is easily seen through them. The body and breast are all green, and that of a very beautiful tinge; but the most remarkable beauty of this creature is its eyes: these are large and prominent, and are of a fine gold colour, and of greater lustre than the most highly polished metal.

The eggs of this fly are a very singular object, and cannot have escaped the eye of any person who is conversant among

the insects which live on trees; though of the many who have seen them, perhaps few or none ever found what they really were. It is common to see on the leaves and pedicels of the leaves of the plum-tree, and several other trees, as also on their young branches, a number of long and slender filaments, running out to about an inch in length, and being of the thickness of a hair: ten or twelve of these are usually seen placed near one another, and a vast number of these clusters are often found on the same tree. The end of each of these filaments is terminated by a sort of swelling or tubercle of the shape of an egg. People who have observed these, have generally supposed them to be of vegetable origin, and that they were a sort of parasitical plants, growing out of others, as the mistletoe, mosses, &c. from the oak and other trees. They very much resemble in figure those species of mouldiness, which Malpighi and others have figured under the shape of little mushrooms, only they are much larger than those little plants, and bear the heat of the sun and other accidents uninjured, which would destroy the tender plants of that kind. There is a time, when these egg-like balls, which terminate every one of these filaments, are found open at their ends, and in this state they very much resemble flowers, and they are in this state figured by some authors under the name of flowers of a singular kind, found on the leaves of the willow. All this, however, is wholly erroneous, and the pursuing the history of our lion-pucerons shews their true origin to be from the fly of that creature. What these authors took for flowers of the willow were only the eggs of this fly, out of which the young animals had been hatched, and had made their escape. The leaves and branches, on which these eggs are found, are usually seen covered over with the pucerons; and the creature providing a place where her young shall find nourishment as soon as hatched, places her eggs in the midst of these harmless and defenceless animals, fixing each on a slender pedicle, yet sufficiently strong to bear its weight. If these eggs be nicely examined, a worm may be discovered in them while yet whole; but the most certain way of judging of them is, to put several of them into a box, in which case every one of them is found at a proper time to hatch, and to give an insect; which, when viewed by the microscope, appears plainly to be a lion-puceron in all its parts, and requiring only increase in size, without any change of shape, to be one of those we have already described, as feeding so voraciously on the pucerons. Reaumur's Hist. Inf. vol. vi. p. 142.

LION, *Ant.* in Zoology. See FORMICA LEO.

LION'S FOOT, *Candia*, in Botany. See CATANANCHE.

LION'S LEAF. See LEONTICE.

LION'S TAIL. See LEONURUS.

LION'S COVE, in Geography, a small bay in the straits of Magellan, surrounded by rocks. The water is deep, the ground is good, and water may be obtained, but no wood. The only refreshments which this bay affords are limpets, muscles, rock fish, and celery. S. lat. 53° 26'. W. long. 74° 25'.

LION MOUNTAIN, a mountain of Africa, near the Cape of Good Hope, deriving its name from a supposed resemblance to the lion. It consists of the Lion's head, which is a bare rock 2160 feet high; and the Lion's tail or rump, which is also rocky, but covered with a slight stratum of earth, 1143 feet high. This earth yields an inferior kind of grass, to which every one's cattle has access. Upon both these summits are erected ensign staves, upon which signal flags are hoisted as soon as any ships are perceived at sea. These signals, whilst the Cape remained in possession of the Dutch, were changed every month; and advices were sent two years before

before to Holland and the India settlements; and sealed letters, containing the detail of them, are given to the commanders of vessels, who are to touch at the Cape; which letters are opened when they arrive within sight of the mountains, that they may ascertain whether or not the place be in the hands of their countrymen, and accordingly avoid it or proceed to an anchorage in the bay. A cannon is also fired on Lion's head, so often as to correspond to the number of ships that appear, in order to give notice to Cape Town; and this notice is facilitated by the reverberation which the sound makes against the steep sides of the Table mountain.

LION D'Angers, Le, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the district of Segré; 10 miles N.N.W. of Angers. The place contains 1728, and the canton 9578 inhabitants, on a territory of 247½ kilometres, in 12 communes.

LIONARDO DA VINCI, in *Biography*. See *Da Vinci*.

LIONCELES, in *Heraldry*, a term for lions when there are more than two of them borne in any coat of arms, and no ordinary between them.

LIONINE, or **LIONADE**, in the history of the *Coins* current in Ireland, a name given to certain coins, imported privately from France and other places. There were, beside these, many others of the same sort, impressed with eagles, roses, and the like, and called by names signifying those impressions. They were a very base and poor sort of money; the penny *lionade*, or *lionine*, not coming up to the value of the halfpenny of the coin of the kingdom. They were discontinued in the year 1300; and good money being struck there, it was made death, and confiscation of goods, to import any of them, and the run of them was thus stopped.

LIONS, in *Geography*, a town of France, in the department of the Eure, and chief place of a canton, in the district of Les Andelys; nine miles N. of Grand Andelys. The place contains 1828, and the canton 9905 inhabitants, on a territory of 125 kilometres, in 13 communes.

LIOSK, a town of Lithuania, in the palatinate of Troki; 20 miles W. of Grodno.

LIOTARD, JOHN STEPHEN, in *Biography*, a painter in enamel, crayons, and miniature, who was born at Geneva in 1702. He went to Paris to study in 1725, and thence accompanied the marquis de Pusieux to Rome, where the earls of Sandwich and Bathorough engaged him to accompany them to Constantinople. There he became acquainted with sir Everard Fawkener, our ambassador, who persuaded him to come to England.

He attempted to make himself conspicuous by adopting the habits and manners of the Levant, and acquired by that and his talents, which were far from contemptible, (particularly in enamel,) a considerable degree of encouragement among the nobility and gentry of this country. But his pictures want grace and taste; he was too close a copyist of what he saw, and did not make his pictures pleasing enough to hold his practice when Rosalba became his competitor in crayons.

LIP, or LIPS, in *Anatomy*. See **DEGLUTITION**.

LIP, Cancer of, in *Surgery*. Such cases as usually go under the denomination of cancers of the lip, are attended with considerable variety, both in regard to the manner in which they begin, and the appearances which they put on in their progress. It is often exceedingly difficult to pronounce, with certainty, whether particular ulcers of the lips ought to be called cancers or not. For, if we can trust to the reports of surgical authors, very inveterate sores upon

the lips are frequently excited and kept up by a disordered state of the abdominal viscera, and many instances at first taken for cancers, have in the end yielded to different remedies. Thus, a painful induration in the lip, which was supposed to be an occult cancer, is recorded to have been cured by the employment of enetic and purgative medicines, especially the *helleborus niger*. (Jourdain, *Maladies de la Bouche*, tom. ii. p. 172.) Richter and other continental surgeons consider it as ascertained, beyond doubt, that many bad ulcers of the lips are connected with gastric diseases, by which we are to understand disorders of the viscera subservient to digestion, as the stomach, liver, bowels, &c. We are informed of a malignant-looking sore of the lower lip, which proceeded from the projection of an unnaturally long incisive tooth of the upper jaw, and which healed of itself as soon as the irritating tooth was extracted. (Jourdain, l. c. p. 196.) Scorbatic sores upon the lips have sometimes been mistaken for cancers, and at length yielded to anti-scorbutic medicines. (Metzger *Adversaria*, vol. ii.) Even sores which have been occasioned on the lips by chilblains, have sometimes been erroneously regarded as cancers. Many ulcers on the lips which at first are quite of an harmless nature, are rendered malignant by the stimulating and caustic applications made use of, almost every unhealthy sore in this situation attracting a suspicion of carcinoma, and leading the hasty practitioner to dress it with irritating and escharotic substances. But the cases which, of all others, are the most liable to be mistaken for cancers of the lip, are venereal ulcers. These are said to have been sometimes cut out by indiscriminating surgeons, who, instead of seeing the wound heal favourably, have had the double mortification of witnessing the return of more extensive syphilitic ulceration in the part, and on the administration of mercury, having their blundering conduct detected by the offended patient, and exposed to the obloquy of the world.

Whoever meditates on the foregoing facts, must be convinced of the impropriety of making hasty and positive decisions, concerning the nature of ulcers on the lips. Bad ill-looking sores are, indeed, formed with particular frequency on these parts of the face; but most of them are not of so malignant and incurable a character, as to merit the appellation of cancer. Many of them, as we have already stated, are exasperated by wrong modes of treatment, and the lips, in consequence of their incessant motion, are unquestionably a disadvantageous place for cicatrization in general.

The diseases to which custom has assigned the name of cancer of the lip, may begin in different ways, and assume various appearances. They often commence in the form of a warty excrescence, which, after attaining a certain size, breaks out into ulceration. They frequently come on in the shape of a phagedenic ulcer; while, in other instances, they begin as a hard lump, which at last falls into the ulcerated state. In some cases much pain is experienced; in others, the degree of suffering is inconsiderable. The occasional causes are subject to equal variety. Sometimes the disease appears to come on of itself. In other examples, its origin is referred to a small pimple, chaf, or excoriation of the lip. We are told of a case, where a cancerous ulcer of the tongue and one side of the mouth occurred, in consequence of inadvertently drinking some liquor, with which an ulcerated cancer of the breast had been washed. (Gooch, *Chirurgical Works*, vol. ii. p. 127.)

The lower lip is that which is commonly affected, the upper one being attacked only in a small proportion of the cases which present themselves in practice. It is also alleged, that the disease is much more frequent in the male than

than the female sex. (Richerand, *Néographie Chirurgicale*, tom. iii. p. 253, edit. 2.) One important fact, in which all the best informed surgeons agree, is, that cancers of the lips and face in general are far less malignant than carcinoma of the breast, or at least, admit of being effectually extirpated with the knife or caustic with more extensive success. The prudent surgeon, before removing a cancerous breast, feels himself obliged to explain the possibility of a return of the distemper; but when the lip is the part affected, and care is taken to remove every particle of the disease, he may be much bolder in his promises.

The medicines usually tried in other cases of carcinoma, may be exhibited in those of cancerous lips. (See CANCER.) The internal employment of arsenic has in particular been much praised. On the whole, however, we have little confidence in any thing but extirpation, and it is only in doubtful cases, that delaying the operation to try the effect of medicines or applications can be very justifiable. Wasting time till the disease affects the lymphatic glands under the jaw, or spreads so extensively, that the wound after the operation cannot be united, is serious misconduct in the surgeon, for the ill consequences to the patient are irremediable. In the first case, the distemper under the jaw mostly cannot be taken away; in the second, if the lower lip be affected, as is commonly the case, great deformity, imperfect speech, and (what is more terrible) a continual slaverling must for ever remain; or at most, admit of only slight palliation by artificial contrivances.

There are now only two modes of extirpating cancers of the lip; one with caustic, the other with a knife.

In these cases, caustic has been very extensively employed, and success may be expected from the method, when the whole of the disease admits of being at once destroyed by a single application. But when the caustic must be repeatedly used, it not only proves in many instances ineffectual, but often aggravates the disease. Nearly all the varieties of caustic have been employed by different practitioners. The great thing is to have one that is exceedingly active, and the Kali purum with quick-lime is as good as any. We have read of a case which was cured by means of a burning glass, though we do not perceive any advantage that this plan can have over the employment of caustic. Comte, *Histoire de l'Acad. Royale de Médecine*, ann. 1776.

Let it not be inferred from the foregoing observations, that we are advocates for the use of caustic, as we frankly own, that although it was our duty to mention the practice, we should be ashamed of adopting it. In every case where caustic can be employed, the knife can always be used with advantage. It does its office more quickly, and with less pain, at the same time that it accomplishes the removal of the disease, and surrounding substance with greater certainty and exactness. But the grand recommendation is, that the wound made with a cutting instrument is such as can be evenly united by the first intention.

Notwithstanding the testimony of the best surgical writers, in support of the very frequent success attending the extirpation of cancers of the lip, one modern author is adverse to making such attempt at all, either with caustic or with the knife. (Jourdain, *Mal. de la Bouche*.) This doctrine, we confess, surprises us a good deal, as being so repugnant to the sentiments which we have derived, not merely from the most accurate books, but from the observation of numerous cures. If M. Jourdain has, in his own individual practice, met with many instances of a return of the disease after the operation, we cannot help suspecting, that his mode of extirpation must have been faulty and incomplete.

Although it is an important maxim in the operation, to

make the wound of such a shape as will admit of an even union, it is a still more important point to remove every particle of the disease. The majority of relapses are unquestionably imputable to the neglect of this material object, and not to the incurableness of the complaint. It is always better to remove too much rather than too little, for the lips are so very yielding, that, in numerous cases, nearly the whole lip has been cut away, and yet the wound has been united without deformity. At the time that we are writing this article (namely August 1811,) there is in St. Bartholomew's Hospital a case, where the greater part of the lower lip was removed by Mr. Vincent on account of a cancer; but, notwithstanding this great loss of substance, the edges of the wound were easily brought into contact.

The operator ought not only to take away all that is manifestly swollen, ulcerated, or indurated; he should be careful likewise not to leave any parts which are at all discoloured. In short, it is safest to make the incisions at some little distance from the perceptible boundaries of the distemper. The extent of the disease upon the inside of the lip will always demand careful examination.

When the whole lip is thoroughly cancerous, the practitioner is under the necessity of cutting every particle of it away, in which circumstance the wound will not admit of union, but must heal by granulations. On the contrary, when the extent of the disease is more moderate, the operator should always make the wound in the manner of that practised for the cure of the hare-lip, so that it may be united by means of the twisted future. (See HARE-LIP.) As the lips are very tensile, this method is generally practicable; and it is well known, that the twisted future may be successfully employed, though two-thirds of the lip have been cut away.

The sooner the operation is undertaken, the greater is the chance of success. Cases only become irremediable through delay, or an ineffectual use of caustic or the knife. The more extensive the malady is, the more difficult it is to cure. The case indeed is past relief, when the distemper has spread to the bones, the gums, the glands beneath the jaw, or any other parts which cannot be removed. The surgeon, however, must relinquish no case where there is a possibility of making an effectual removal of the morbid parts.

The mere magnitude of a cancerous tumour is not prohibitory of the operation. In one case, excision was performed most successfully, notwithstanding the excrescence was so large as to hang down on the breast. (Le Drac, *Observ.* tom. i. p. 78.) In another example, the operation had the happiest consequences, although the inside of the lip and cheek felt as rough as if it had been smeared all over with sand. (Richter's *Anfangsgr. &c.* Band 2, p. 326.) Richerand upbraids with timidity, surgeons who are stopped by the extent of the malady, and he contends, that extirpation should be undertaken, even though it be necessary to separate the soft parts from the lower jaw bone, provided the glands under the chin are free from disease. He informs us, that Chopart, after removing in one case the whole of the lip, and a portion of the cheek, was obliged to cover the denuded jaw with the integuments of the neck. Notwithstanding such loss of substance, the wound healed; the opening of the mouth remained for a time contracted; but it serves (says this author) for the admission of aliment, and gradually becomes larger, the power of better pronunciation also returning. *Néographie Chirurgicale*, tom. ii. p. 252. edit. 2.

Whenever the case is such, that an attempt to unite the wound can be practised, the surgeon must take away a triangular portion of the diseased lip, so that the incision may

referable

refenable the letter V, and its edges be easily brought together with the twisted future, as in the operation for the hare-lip.

The union of wounds of the lower lip is an exceedingly important object, since, besides the deformity, a more serious grievance arises from the separation, namely, the continual involuntary discharge of the saliva, which is naturally confined within the mouth by the lower lip. Nothing can be more annoying than such an infirmity, and by impairing digestion, it also proves extremely hurtful to the health. A patient whose lower lip is so extensively diseased, that extirpation cannot be effected, without inducing this affliction, is in a truly pitiable state.

That the health suffers greatly from the incessant loss of the saliva, is a fact confirmed by numerous cases. A woman had a cut through her lower lip, and the wound, being neglected, suppurated, and its margins healed. The consequence was that the saliva constantly escaped from her mouth, and from being a healthy-looking woman before the accident, she became rapidly emaciated, afflicted with stomach complaints and difficulty of digestion. Tronchin, being consulted, saw that her indisposition proceeded from the loss of a nutritious fluid. He advised uniting the division by the operation for the hare-lip. This was actually done by Ferrand. The loss of the saliva was prevented, and the patient soon regained her health and good looks again.

It would seem that children can bear the loss of a large quantity of the saliva better than adults. A little girl, six years old, was brought into the hospital of St. Louis, afflicted with a gangrenous carbuncle, that had not only spread to the whole lower lip, and soft parts about the chin, but also to the body of the jaw. The sloughing having stopped, the dead parts were detached, the body of the lower jaw-bone separated from the rami at the places of anatomical division. In this case, the circumstance particularly worthy of notice is, that although the saliva was incessantly running out of the mouth, so as to wet all the girl's clothes, she enjoyed, during the six months she was in the hospital, a good appetite, and had every appearance of being well nourished. See Richerand's *Nosographie Chirurg.* tom. iii. p. 255, edit. 2.

LIP, *Hare,*

LIP, *Preternatural Fissure of,* } See HARE-LIP.

LIP, *Wounds of.* In these cases the chief indication is to place the edges of the division in exact and even contact, in order that they may unite by the first intention. The twisted future will generally be found the most advantageous for this purpose. It is to be applied in the manner explained in the article HARE-LIP, in conjunction with narrow strips of adhesive plaster, and a bandage that will press forward the integuments of the face. Whether one or two pins ought to be used must depend upon the length of the division. When the wound is lacerated, or contused, it often cannot be hindered from suppurating, and union by the first intention is prevented. However, in such instances, a pin may frequently be employed with benefit, as a partial adhesion may take place, though the agglutination is not general. And even when these wounds suppurate, maintaining the edges near each other with strips of adhesive plaster will materially lessen the breadth of the scar, and expedite the cure. Sometimes it may be proper to poultice a contused or lacerated injury of the lip, where there is no immediate prospect of adhesion, and the part has a sloughy aspect; but this plan should only be continued till the wound puts on a cleaner appearance and begins to granu-

late; the proper method being now to apply adhesive plasters, and a pledget of any common unirritating ointment.

LIP of a Horse, in the *Manege*, is the skin that covers the sides of the mouth, and furrounds his jaws. A horse is said to arm or guard himself with his lips, when his lips are so thick that they cover their bars, and keep off the pressure of the curb.

LIPA, of λιπος, *fat*, a word used frequently by Hippocrates to express any thing fat or oily. He calls certain stools, which have a fatty appearance, by this name. These are esteemed a sign of great colliquation. He also applies it to a sort of fatty substance, often seen swimming on the surface of the urine like a spider's web: this the same great author gives as a sign of a consumption.

LIPA, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 32 miles W. N. W. of Sluck.—Also, a town of Croatia, on the river Dobra; 10 miles S. W. of Carlstadt.

LIPARÆUS LAPIS, in the *Natural History of the Ancients*, the name of a stone usually found in Lipari, one of the Æolian islands, and brought thence in the time of the Greeks among the pumices, of which that place always afforded them a large quantity.

It was a small stone, about the bigness of a filbert, of an irregular and uncertain shape, and porous and friable constitution, like that of the pumices, but more easily falling to pieces on rubbing between the fingers than even the softest of them; the colour was a dusky grey, and the whole external surface plainly shewed that it had suffered changes by the means of fire. The stone at present, however, is so little regarded, that the writers on such subjects have even forgot to name it. They are sometimes brought to us, to this day, among the pumices from the burning mountains, but are not regarded.

LIPARI, in *Geography*, a volcanic island, or rather a group of such islands, in the Mediterranean, about twenty-four miles from the N. coast of Sicily. They were formerly called *Æolian Islands*, which see; and now *Isole di Lipari*, from the name of the chief of them. These islands were anciently known to be volcanic, and called *Volcanian*, but it is in modern times that their volcanization has been considered as an object of interesting research to philosophers, among whom M. de Luc, sir W. Hamilton, Dolomieu, and Spallanzani have distinguished themselves. These islands are commonly reckoned ten in number, though some by omitting and others by comprehending some barren rocks, have diminished or increased their number. The largest is Lipari, being 19½ Italian miles in circuit. Accordingly this island, from its extent, the city which renders it illustrious, the number of its inhabitants, its agriculture and commerce, claims pre-eminence above all the others by which it is surrounded. Nor is it less important in the estimation of the naturalist from the quantity, variety, and unusual beauty of the volcanic products which it contains. It is well known, by the testimony of Diodorus (l. 5.), that all the Æolian isles were subject to great eruptions of fire, and that their craters and mouths were visible in his time. As to Lipari, however, very few memorials have been preserved of its ancient conflagrations. Of the antiquity of the island, and of its existence before the Trojan war we are certain, since we learn from Homer, that, after the taking of Troy, Ulysses landed there, and was treated with the utmost urbanity and courtesy by king Æolus, during the whole month of his continuance there (*Odys. l. 10.*); and though we allow to the poet the usual licence of poetry, it is still most certain that he could not have named this island, and the city it contained, unless they existed at the time when he wrote his poem, above

3000 years ago. But if we consult other ancient and credible writers, we shall find that before *Æolus*, *Liparus* reigned in this island, and that from him it took its name, being before called "*Melogonis*," or, according to others, "*Meligunis*." The antiquity of this island may also be inferred from the manner of its production by subterranean eruptions, in which the decomposition of volcanized matters is necessary, which requires a considerable interval of time. If, therefore, *Lipari* had inhabitants and cities, and was a cultivated country before the destruction of *Troy*, it is evident that it must have existed many ages prior to that event. But from the time when mention is made in history of this island to the present day, it is pretty certain that no true eruption or current of lava has taken place in it; for if this had been the case, some memorial would have been preserved of it as well as of those of *Stromboli* and *Vulcano*. The stoves and the warm baths of *Lipari* are the only places in the whole island where any signs remain of unextinguished volcanos. *Spallanzani* made a circuit of this island for the purpose of first examining its shores, and he then ascended its mountains in its interior parts. In examining its shores, he began with the city of *Lipari*, which extends along the shores in the form of an amphitheatre; and in his researches in the harbour itself, under the castle of the city, he found that it is erected on an immense rock of lava, that rises perpendicularly from the water, and is entirely destitute of all vegetation, except a few stalks of the Indian fig (*Cactus opuntia*, Linn.) which grew in its fissures. This lava has for its base feldspar, is of a fine compact grain, of a scaly fracture, dry to the touch, and gives sparks, like flint, with steel. The colour is cinereous, approaching in many places to that of lead. This lava is joined to large masses of glass, which form a whole with it, without any separations or divisions in the middle. It is therefore the same lava, either retaining its own nature or transmuted into glass. This glass, like the lava, gives sparks with steel; but the lava is opaque, whereas the glass, in the angles and thinner edges, has a considerable degree of transparency. The ancient existence of fire in this place is evinced by another circumstance, *viz.* that the vitreous substances already noticed are frequently accompanied by pumice, which are, in fact, only an imperfect glass. In viewing the steep masses of glass and lava, which rise perpendicularly from the sea, like a wall, they are seen to be interspersed with different strata of pumice, which is of two kinds; the one heavy and compact, the other light and porous, and both of a cinereous colour. The first sort is of the same nature with the lava of the rock; but the other kind is rather scaly than filamentous, and its scales have a degree more of vitrification than the other. This pumice is usually a continuation of the other, and, according to our author, derives its origin from the greater degree of heat which it has sustained. Upon attentively examining this mixture of lava, glass, and pumice which forms the body of the rock, it appeared evident that there must have been several currents that had flowed down the sides, and, perhaps, from the summit, of the contiguous mountain *Della Guardia*, into the sea; since the direction of their descent is found on that side, and even the filaments of the pumices point towards that mountain. The lava, glass, and pumice exhibited neither feldspars, shorls, nor any other extraneous body, either, as our author conceives, because they have melted by the fire, or, perhaps, because they never existed in them. The lava and glass of the rock, when exposed to the furnace in separate crucibles, fused into a light-grey glass; the globules which before appeared in them melting at the same time; during liquefaction these substances, which filled only one quarter part of the crucible,

swelled so much, that they rose several times above the edges of the crucible, and flowed over its sides. The two kinds of pumice, though both derive their origin from the same feldspar, which is the base both of the lava and the glass, afford different results in the same fire; since their volume, instead of being augmented, is diminished, only retaining its former colour.

The haven of *Lipari* forms a curve in the shore, which to the south begins at the foot of the *Monte Capifullo*, and ends to the north-east at the bottom of the *Monte della Rosa*. After having examined that part of the shore which is contiguous to the harbour, lying under the castle, and on the right side of *Monte Capifullo*, our author made the circuit of the remainder of that curve to the base of *Monte della Rosa*. The objects that here attracted his notice were first a tufa, which the industry of the inhabitants had converted into a soil suitable to small vineyards, and next a mass of crags and precipices, partly fallen into the sea, and partly threatening to fall; among which, besides scoræ of an iron colour, he met with beautiful volcanic breccias of lava of a petrosiliceous base, containing small particles of glass and pumice. At the foot of the *Monte della Rosa*, where the harbour of *Lipari* ends, our author perceived on the shore a stone, which, from its singularity, drew his attention. It formed a rock rising in part above the sea, and in part concealed by the water. It was at first taken for a jasper: its ground was of a red-blood colour; it gave sparks strongly with steel, was of a rather fine grain, and had almost the hardness of quartz. On a more attentive examination this stone was perceived not to be simple like the jasper, but of a compound formation, containing in it reddish scales of feldspar and shorls, which gave it the character of that kind of porphyry which has for its base a hard horn-stone. This substance our author, after careful investigation, cannot exclude from the number of true and real lavas, though he cannot affirm that its redness is an effect of calcination, as is the case in other lavas, since of this it does not exhibit the slightest indication. The reasons of fact on which *Spallanzani* grounds his opinion, that this porphyritic rock has passed into the state of lava, are two; the great number of minute cells it contains in many parts of it, and the direction of those cells. Hence he concludes, that this stone is not only a true porphyritic lava, but that it once flowed from the mountain to the sea, and in its motion the naturally circular figure of its pores or cells was changed into an oval. The same appearance has always been observed, on a smaller scale, in re-melted lavas, and glasses. All the species of this kind of lava are not, however, of a blood-red colour; some of them are of a duller red, though the component principles of both are essentially the same. This lava, when fused in the furnace, doubled its volume, and its upper part assumed a vitreous convexity, which was smooth, shining, semi-transparent, and of a greenish tincture; but internally it was a very black vitreous scoræ, extremely porous, and sufficiently hard to give sparks with steel.

In pursuing his tour our author found that *Lipari*, like the other *Æolian* isles, is at its base more or less corroded by the sea, which is frequently in a state of violent agitation: the lower excavations cause the parts above them to give way, and, in a series of years, great masses fall into the sea. To this the nature of the lava, which is full of cracks and fissures, considerably contributes; not to mention the influence of the humidity of the atmosphere, and other destructive elements. Large heaps of these fragments accumulate on the shore, and make room for others, and thus a gradual diminution of the island takes place. Beyond the harbour

harbour and the porphyritic rock, our author found the sea forming a kind of bay within the land, round which a few cottages are built, affording shelter to a small number of inhabitants, who subsist by the profits of a vineyard that ill repays their labour. The name of this place is Canneto; and above it is a current of lava, of an argillaceous base, similar to that of the Arlio in Sicily. At the distance of three miles from the haven of Lipari is Campo Bianco (the White field), so called, because it is a lofty and extensive mountain, composed entirely of white pumices. For the nature, production, and properties of *Pumice*, we refer to that article. The mountain, which is a prodigious mass of pumice, rises almost perpendicularly from the sea, and, seen at a distance, appears to be about a quarter of a mile in height, and above half a mile in breadth. No plants grow upon it, except a few without fruits, like those on the tops of the Alps. Its sides are streaked with numerous furrows, widening and deepening as they approach the bottom, and formed by the rains, which easily corrode and excavate a substance so soft and yielding as pumice. The sea at the bottom has likewise occasioned great devastations, by means of which is laid open to view a large vein of horizontal lava, on which the last wave dies away when the sea becomes calm. The formation of this lava was, therefore, prior to the vast accumulation of pumices which rest upon it. This mass of pumice is an aggregation of numerous beds, or strata, of pumices, successively placed on each other, distinguishable by their colour and by their projection from the mountain. Some of these pumices are so compact that the smallest pore cannot be discerned, nor do they exhibit the least trace of a filamentous nature. With a lens they appear to be an irregular accumulation of small flakes of ice. Others are full of pores and vacuities of a larger size, usually round; and their texture is formed by filaments, and streaks, generally parallel to each other, and of a shining silvery whiteness. Of these pumices there are three kinds, which the people of Lipari dig for sale. One kind is employed in polishing different substances, and the other two kinds are used in the construction of arched vaults, and the corners of buildings. There are other kinds which merit the attention of the natural historian. In examining these pumices our author obtained the following results:

	1st Species of Campo Bianco.	2d Species.	3d Species.	4th Species.	Pumice of the rock of the castle of Lipari.
Silex	60.3	80	80	61	63
Alumine	23	6	4	22.7	24
Magnesia	6	3	2	6	5.6
Lime	6	4.7	4	5.8	3
Iron	3	4.8	5.3	3	2

Beyond Campo Bianco and its adjacent hills, rises a mountain of another kind, called the Monte della Castagna, which, in the part of it descending to the sea, is about one mile in extent, and above four miles in circumference. This mountain, according to Dolomieu and our author, is entirely composed of enamels and glasses. For the description of these in their number and variety, we must refer the reader to the work before us. Campo Bianco and the Monte della Castagna, though apparently isolated, are in reality a connected group, taken in its whole extent, having a circuit of eight miles; nor is the extent of its vitrifications less, if in these we include likewise the pumices, which are in fact only a less perfect glass. The sterility of these mountains is a consequence of their vitreous nature, which, in the course of so many ages, has not been decomposed into a vegetable earth: if we except a few lichens attached

to the fissures of the glasses, there is no vestige of a single living vegetable over the whole Monte della Castagna; and on Campo Bianco they are extremely rare. Beyond the pumices, the lavas again appear, beginning from the "Punta del Segno Nero," and extending in a chain of several miles, which on the side of the sea descends in precipices and craggy declivities: and proceeding further, the sea makes an incurvature and forms a small bay, called the Valle di Muria, on the sides of which rise high and steep rocks of lava, half demolished, and among the lava enamels and pumices. In examining the interior of the island, Monte San Angelo, situated to the north of the city of Lipari, is the highest mountain, on the summit of which is a circular plain, surrounded by eminences shelving towards the inside, which M. Dolomieu imagined to be the remains of an ancient crater, and which he supposes to have been the first that was formed in the island, about a mile above the sea, through which the volcano burst forth, and which served as a base and support for the other mountains that were thrown up afterwards. Soon afterwards rose its companion, the Monte della Guardia, which looks towards the south, and little inferior to the other in height. These two mountains formed two islands in the sea, which, enlarging each its respective base, united into one. To these two mountains subsequent eruptions made new additions, until at length the whole island of Lipari was produced, which, from the erosions of the rain and sea, is now certainly less than it once was.

Lipari, if we except some few flat places and practicable declivities, which the inhabitants have rendered cultivable by great labour, is a ruinous pile of horrid precipices, rugged cliffs, and enormous masses; and there is no summit, nor projecting part of a mountain, which does not exhibit manifest indications of its future fall and destruction. The materials of which these ruins are formed are pumices, enamels, and glasses, similar to those which we have already mentioned.

The celebrated flices of Lipari have exercised the curiosity of travellers. These lie four miles W. of the city, and somewhat beyond the summit of a mountain, which, next to those of San Angelo and della Guardia, is one of the highest in the island. The road from the city to the flices is formed by a deep excavation, chiefly the work of rain-waters, in an immense mass of tufa. Our author conceives that the volcanic tufas have been formed by slimy eruptions; without denying, however, that ashes, sand, and other subtile matters ejected by volcanoes, and penetrated either by the rain-waters, or those of the sea, where they covered the bases of the burning mountains, have been consolidated into some tufas. The tufa of Lipari, to which we now refer, has every appearance of having been an earthy current in our author's opinion. It begins at about 100 paces from the city, and continues, without interruption, to beyond the summit of the Monte della Stufa, or Mountain of the Stoves. (See Tufa.) The flices, terminating a descent of about 200 feet in length, form a group of four or five caves, more like to the dens of bears than the habitations of men, and exhibiting much less art than the edifices formed by the beaver. Every cave has an opening at the bottom, through which the warm and humid vapours enter, and another in the top, through which they pass out. On one of these flices the thermometer stood at only 48°; but the vapour possesses somewhat of a suffocating nature. The flices now retain little more than their name, and whatever may have been their supposed virtue in the cure of disorders, they are now nearly deserted. Under the flices, and the adjacent

ground, there is reason to believe, that some remains of sulphureous conflagrations still continue.

Lipari, we have already observed, is the largest, and it is also the most populous of those called the Æolian isles; the number of its inhabitants amounting to between nine and ten thousand, most of whom reside in the city of the same name. If the island be divided into four parts, about $2\frac{1}{2}$ will be found to be cultivated, and the remainder overgrown with wood, and barren. These barren tracts, however, are gradually converted into fruitful fields, from a kind of necessity arising from the continually increasing population of the island. Lipari produces cotton, pulse, and olives, in small quantities. The corn is scarcely sufficient for the supply of the city. The principal of the useful productions of this island are the grapes, of which there are several kinds. The first furnishes the common wine that is drank in the island, and of which they export annually two or three thousand barrels. The passole and passolina, as they are called in the island, are two other kinds of grapes that are dried. The last is that sort which is usually called the Corinthian grape. Of this they commonly sell 10,000 barrels annually; and of the other about 12,000. From a fourth kind of grape is made the famous Malvasy of Lipari; which is a wine of a clear amber colour, generous and sweet. The grape producing this wine is scarce, and does not furnish more than 2000 barrels annually, which are sold for foreign markets, as well as the passole and passolina. The vintage is in the month of September, which is a season of relaxation and festivity to the Liparese. Another plant of domestic use to the Liparese, if it does not form a branch of foreign commerce, is the Indian fig (*Cactus opuntia*, Linn.) Nothing can be more wretched than the fishery of Lipari. In June and July they fish for coral; but owing to a want of skill, this fishery is very unproductive. At Lipari large and small cattle are very scarce; and the few oxen and cows which are slaughtered there are brought from Sicily, and are very lean. Of wild quadrupeds, the country only produces rabbits, which make their burrows in the mountainous parts, where the volcanic matters, principally of the tufaceous kind, permit them to dig with their feet. The birds stationary here are but few, viz. the partridge, green-finch, sparrow, gold-finch, horn-owl, and raven. Of migrating water-fowls, here are different kinds of sea-gulls and the cormorant. The birds of passage are the turtle-dove and the quail, which come for a few days in April and September. Several kinds of swallows are common.

Foreign commerce has begun to be introduced into the island by the mariners; they every year buy, at the fair of Sinigaglio, linen, muslins, veils, and other commodities of that kind; and sell them at Messina, Catania, Palermo, and other parts of Sicily. The trade is very advantageous to the country, and many have acquired considerable wealth; though it injures the fishery and raises the price of fish. Strabo, Diodorus, and Dioscorides say, that the sulphate of alumine (alum) was procured in great abundance at Lipari; but none of this salt is now extracted in the island.

The political administration of Lipari is composed of a criminal judge, a fiscal, a governor, who has the chief authority both in military and civil affairs, and who is commonly an old invalid; and a civil judge. The bishop, seventeen canons of the first order, and fourteen of the second, and from 120 to 130 priests, form the ecclesiastical establishment. The Liparese are, in general, of a prompt and lively wit, ready to learn, of acute penetration, and very desirous of obtaining knowledge. A beggar is scarcely ever found in this island; for the poorest persons have some

small piece of ground which they cultivate, and by the produce of which they live. The natives are rather of a large size, robust, and comely. The heat of the sun, however, injures their fine complexions, producing tanned skins and swarthy countenances. The Liparese, in general, value themselves upon being good mariners, both in theory and practice. Spallanzani's Travels in the Two Sicilies. &c.

LIPARI, an ancient city of the above island, forming an amphitheatre along the shore, with a chain of mountains behind it, not of an extensive circuit, and consisting rather of narrow alleys than streets. The castle is surrounded with a wall, on which are erected a few cannon, and is defended by a small garrison. The houses are indifferent buildings; but three edifices are distinguishable from the rest; viz. the palace of the bishop, the house of the governor, and the cathedral church. The latter contains very costly sacred utensils, a great quantity of plate, and a number of silver images, among which is the statue of St. Bartholomew, their patron saint. The value of this treasure is said to amount to 90,000 Neapolitan scudi; the scudi being worth about 4s. 3d. N. lat. 38° 35'. E. long. 15° 12'.

LIPARIA, in Botany, so named by Linnæus, in his second *Mantissa*, in allusion either to the smooth or sleek habit of *L. sphaerica*, from which his idea and character of the genus was taken, or to its rich and splendid appearance, for the Greek word *λεπτός* will justify either explanation. Professor Martyn gives the former; we prefer the latter.—Linn. Mant. 156. Schreb. 499. Willd. Sp. Pl. v. 3. 1114. Mart. Mill. Dict. v. 3. Thunb. Prodr. 123. Ait. Hort. Kew. ed. 1. v. 3. 48. Juss. 353.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. Cal. Perianth of one leaf, inferior, very obtuse at the base, divided half way down into five acute segments, the lowermost of which is very long, elliptical, and resembling a petal. Cor. papilionaceous, without any spurs or elongations to the keel or wings. Standard oblong, folded, straight, reflexed at the sides. Wings oblong, straight, narrower at the base, two-lobed at their inferior margin. Keel lanceolate, slightly ascending, divided deeply at the base. Stam. Filaments in two distinct sets; one simple; the other in nine divisions, which are thread-shaped, three of them shorter than the rest; anthers ovate. Pist. Germen sessile, very short; style thread-shaped, of a moderate length; stigma simple. Peric. Legume ovate. Seeds few.

Eff. Ch. Calyx in five segments, the lower one elongated. Wings of the corolla two-lobed at the lower side. Three of the united stamens shorter than the rest. Legume ovate.

This splendid genus of shrubs, from the Cape of Good Hope, is in every respect closely allied to *Borbonia*, next to which it ought to stand in the Linnean system, though Murray, who has been heedlessly followed by others, widely separated them. *Liparia* differs from *Borbonia* in being truly diadelphous. How far the other characters indicated in their descriptions hold good, we have not sufficient acquaintance with all the species of either genus to determine, but there is no difference with regard to habit or appearance. Two species are described by Linnæus, Mant. 268, 269, and four more indicated with doubt, amongst which is *Spartium capense*, (*Crotalaria eppysia*, Linn. Suppl. 322.) The rest stand as *Liparis* in Syst. Veg. ed. 14. 665, making five in all, to which eight are added by Thunberg, and the whole thirteen are admitted by Willdenow. The habit of the genus is rigid, with numerous, scattered, sharp, usually elliptical, rarely linear leaves, which are either smooth, hairy, or silky. Flowers, as far as we know, of a

fine rich yellow, in terminal heads or umbels. Examples are

L. sphaerica. Linn. Mant. 268. Andr. Repof. t. 568. Curt. Mag. t. 1241.—Flowers numerous, in bracteated drooping heads. Leaves elliptic-lanceolate, ribbed, smooth.—According to Andrews this was raised by Mr. Milne, gardener at Fonthill, Wilts. We received it from Mr. Anderson, curator of the splendid collection of James Vere, esq. at Kensington Gore. The *shrub* is five or six feet high, clothed with numerous, spreading or recurved, glaucous leaves, above an inch long, entire, and strongly ribbed. The large drooping round heads of golden flowers, are singularly magnificent, accompanied by numerous reddish bractes, differing from the leaves chiefly in colour and situation. The whole plant unavoidably turns as black as ink in drying. It blossoms in May.

L. graminifolia. Linn. Mant. 268.—Flowers capitate. Calyx hairy. Leaves linear-lanceolate, smooth.—Grows in a sandy soil at the Cape. We have seen it in a dry state only, nor is any figure extant. The very narrow leaves, an inch or inch and a half long, and about a line wide, are peculiar, as well as the hairy heads of flowers, much smaller than those of the foregoing. The branches are angular and smooth.

LIPARIS, a name given by some authors to the pin-guicula, butter-wort, or Yorkshire fanicle.

LIPARIS, in *Ichthyology*, a species of *Cyclopterus*; which see.

LIPARIS *Noftras*, the name of a small fish, common on the coasts of Yorkshire, and some other parts of England, and called in English the snail, and limax marinus by some authors. It is about five fingers long; on its back and sides it is of a bright brown, and on the belly of a fine white: these are its colours, when fresh taken, for when it has been kept ten or twelve hours, the whole surface of the body, except the fins, becomes of a paler and bright brown. The head is thick, and not flat, but rounded; it has no teeth, but its jaws are both rough like files.

The whole fish, head as well as body, is very soft and unctuous, and easily melts into a sort of oily liquor. It is caught principally at the mouths of great rivers where they open into the sea.

LIPAROCLE, from *λίπος*, fat, and *κλῆρ*, a tumour, in *Surgery*, any kind of tumour composed of fat.

LIPAVINA, in *Geography*, a town of Croatia; 12 miles E.N.E. of Creutz.

LIPCZANI, a town of Poland, in the palatinate of Braclaw; 60 miles W.S.W. of Braclaw.—Also, a town of Moravia, on the Pruth; 24 miles S.S.E. of Choezim.

LIPENIUS, MARTIN, in *Biography*, a German Lutheran divine, known only by his works, which are “On the Navigation of Solomon’s Ships to Ophir,” 1661; “A Treatise on Christmas-Boxes or New-Year’s Gifts;” but his most important work is entitled “*Bibliotheca Realis*,” in 6 vols. folio; consisting of a view of all the subjects into which the different sciences are branched, with a catalogue of the names and works of the various authors who have treated concerning them. Moreri.

LIPES, in *Geography*, a town of Peru, and capital of a jurisdiction, under the viceroy of Buenos Ayres; 150 miles S.S.W. of Potosi. S. lat. 21° 40'. W. long. 68° 16'.

LIPETSK, a town of Russia, in the government of Tambov, on the Voronez; 40 miles W.N.W. of Tambov. N. lat. 53°. E. long. 40° 24'.

LIPETZ, a town of Bohemia, in the circle of Konigin-gratz; 9 miles S. of Neu Biezow.

LIPINSKOI, a town of Russia, in the government of Novgorod; 16 miles S.E. of Novgorod.

LIPNISKI, a town of Lithuania, in the palatinate of Wilna; 20 miles E.N.E. of Lida.

LIPNITZ, a town of Bohemia, in the circle of Czaflau; 6 miles W. of Teutfeh-Brod.

LIPNO, a town of the duchy of Warsaw; 12 miles N. of Dobrzyn.

LIPODERMUS, or LEIPODERMOS, (from *λεῖπω*, to leave, and *δέρμα*, the skin,) in *Surgery*, wanting the prepuce.

LIPORANO, in *Geography*, a town of Naples, in the province of Otranto; 3 miles S. of Tarento.

LIPOTHYMYA, or LIPOPSYCHIA, in *Medicine*, from *λεῖπω*, deficio, and *δύμος*, animus, or *δύχη*, anima, signifies a sudden faintness, or temporary deficiency of the nervous power, and of all the functions depending upon it. It is called also *deliquium animi*, swooning, syncope, &c. See SYNCOPE.

LIPOWE, in *Geography*, a town of Lithuania; 25 miles N.N.E. of Braclaw.

LIPOWIEC, a town of Austrian Poland, on the Vistula, to which belongs a castle on a rock, used as a prison for ecclesiastical offenders; 20 miles W. of Cracow.

LIPPA, a town of Hungary, on the Maros; 22 miles N. of Temeswar.

LIPPE-SHAUMBERG, WILLIAM, Count, in *Biography*, son of Albert Wolfgang, count Lippe and Schaumberg, by a daughter of count Oynhausen, was born in 1724 at London, but was sent, in 1735, to Geneva, to complete his education. Here he devoted much of his time to the study of mathematics, as connected with the military art. In 1740 he returned with his brother, and in the following year they were both sent to the university of Leyden, from which they removed in a short time to Montpellier, in France. At the age of eighteen he repaired to England, and obtained an ensign’s commission in the first regiment of guards. On the death of his eldest brother he returned to Buckebourg, the family residence, in Germany, and soon after accompanied his father, a lieutenant-general in the Dutch service, during the campaign in the Netherlands, and was present as a volunteer at the battle of Dettingen, where he was distinguished as well for his good conduct as for his bravery. In the year 1745 he joined the Austrian army in Italy, and was promoted, in consequence of his services, to be a colonel in the Austrian army, but he declined acting under the commission. In 1746 he travelled over a considerable part of the continent, and from thence he came to England, where he remained till he succeeded to his paternal estates in 1748, when he repaired to Berlin, to surrender into the hands of his Prussian majesty the order of the Black Eagle, which had been conferred on his father. Here he formed an acquaintance with many persons of distinguished literary merit, and he was elected a member of the Academy of Sciences. After this he was distinguished as a military man in the Prussian army, raised a regiment of grenadiers from among his own subjects, and was honoured by Frederic with the order of the Black Eagle. In 1754 he established a foundery at Buckebourg, where he had all the cannon cast which he afterwards employed in the seven years’ war against the French. In 1756 he entered into a treaty with Great Britain, by which he engaged to assist his Britannic majesty in the defence of his German dominions against the arms of the French, and to furnish for that purpose a regiment of infantry of a thousand men, a corps of artillery, and another of carbineers and chassurs. He was present at the battle of Minden, and in many other posts of much danger. In 1758 he was ordered to withdraw his forces from the allied army,

army, and join the Austrians against the king of Prussia: he refused, though at the risk of being put under the ban of the empire, and continued faithful to the engagements which he had entered into with England. In 1759 the count obtained the command of the whole artillery of the allied army; took a considerable share in the battle of Todenhausen, and the success of the day was in a great measure owing to the artillery of which he had the command. He was in the same year successfully engaged in the sieges of Marburg and Munster. On his return home, in 1760, he formed an artificial island in the Steinheeder lake, which is a mile in length, and half a mile broad, and being surrounded by morasses, is without the reach of cannon. Here he constructed a fortress, which was considered as impregnable, and it contains, besides the usual apartments, a chapel, and a library furnished with the best books on engineering, a collection of models, another of natural curiosities, and lodgings for the officers, with a school for engineers, and an observatory. In 1761, when the war broke out between Spain and Portugal, count Lippe was appointed by his Britannic majesty as commander-in-chief of the British troops sent to the assistance of the latter. He was afterwards entrusted with the command of both armies, and in 1762 proceeded, by way of England, to Portugal. Soon after his arrival, the king ordered the sum of forty thousand crusadoes to be paid him for his establishment, but he immediately distributed one-half of the money among the soldiers, and sent back the remainder, except what was sufficient to pay for his uniform of field-marshal, to the king. His majesty even offered him a pension of 3000*l.* but this the count declined, and nothing could induce him to accept of that remuneration of his services to which he was unquestionably entitled. By his exertions principally, Portugal was protected from the danger threatened to it by her powerful and ambitious neighbour. The king of Portugal, Joseph I. who knew how to appreciate count Lippe's talents, employed him in a civil as well as military capacity, and, in consequence of his advice, introduced many improvements into the political administration of the kingdom, and particularly into the financial department. His principal object was to establish the army on a respectable footing, and to inspire the soldiery with a more delicate sense of honour. The war which he carried on with Spain was merely a defensive one, but he effected more by it than he could by one of a contrary description, as he was enabled to throw so many obstacles in the way of the enemy, that their plans were rendered entirely fruitless. In 1763, before he left Portugal, he established a school of artillery, and constructed on the Spanish frontier a very strong fortress, which, in commemoration of his name, was called Fort Lippe. At the general peace the count returned to Germany, carrying with him abundance of presents from the kings of Portugal and England, in testimony of their esteem and approbation. He now employed much of his time in the study of the military art, and in bringing his theories to the test of practice. As the result of his experience and observations, he wrote a treatise on the art of defensive war, in six small volumes, which is said to possess much merit, but of which he had only ten copies printed. In 1767 he revisited Portugal by the king's invitation, and completed the reform which he had begun in the Portuguese army. In the following spring he returned to Germany, and soon after was honoured with a visit from Frederic II. of Prussia. The remainder of his life he employed in promoting the prosperity of his states, and the happiness of his subjects. He died in 1777, in the fifty-fourth year of his age. Sublime thoughts and heroic sentiments had been as familiar and natural to his mind as they

were to the noblest characters of Greece and Rome. The animation of his features announced the elevation, sagacity, penetration, kindness, virtue, and serenity of his soul. In his retirement he amused himself with the arts and sciences, but his favourite studies were philosophy and ancient history. He possessed an extensive knowledge in every department of literature, and by his travels in foreign countries he had become familiarly acquainted with the French, English, Italian and Portuguese languages: he was an excellent draftsman, a great connoisseur in paintings; and excelled so much in music, that he was able to direct the concerts which were given in the evening at his residence. Gen. Biog.

LIPPE, in *Geography*, a county of Germany, W. of the bishopric of Paderborn, divided into several branches, which derive their names from the different towns and parts of the principality belonging to each. The country, generally mountainous, contains some good arable land. Its chief towns are Detmold and Lemgow, and the principal rivers are the Emmer and the Werra. It now forms a part of the kingdom of Westphalia.—Also, a town of Westphalia, called *Lippstadt*, on a river of the same name; 14 miles W. of Paderborn. N. 51° 39'. E. long 8° 24'.

LIPPEHNE, a town of the New Mark of Brandenburg; 26 miles N. of Custrin. N. lat. 53° 4'. E. long. 15° 3'.

LIPPI FRA. FILIPPO, in *Biography*. Concerning the exact date when the birth of this very excellent historical painter took place, authors differ extremely. The most probable account fixes it about the beginning of the fifteenth century, as he was a scholar of, and of course nearly contemporary with, Massaccio. At the age of sixteen, being entered a novice in the convent of Carmelites at Florence, where he was born, he had there an opportunity of seeing that extraordinary artist at work upon the astonishing frescoes with which he adorned the chapel of Brancacci, in the church there; and became eager to embrace the art he saw capable of so much effect in affording gratification, instruction, and interest to the mind.

Such was his success, and so did he enter into the principles and manner of his great master, that after the death of the latter, it was said, by common consent, that the soul of Massaccio still abode with Fra. Filippo.

He forsook the habit of his convent, and devoted himself entirely to painting; but his studies were for a time disturbed by his being unfortunately taken, while out on a party of pleasure, by some Moors, and carried prisoner to Barbary; where he remained in slavery 18 months. He obtained his liberty by his talents. He drew the portrait of his master upon a wall with so much spirit and accuracy in resemblance, that he, being struck with the ingenuity of his slave, and generously feeling compunction in confining a man of such useful talents, gave him his freedom as a reward.

On his return home he painted some works for Alfonso, king of Calabria. He employed himself also in Padua; but it was in his native city of Florence, that his principal works were performed. He was employed by Cosmo di Medici; who presented his pictures to his friends; and one to pope Eugenius IV. He was also employed to adorn the palaces of the republic, the churches, and many of the houses of the principal citizens; among whom his talents were held in high estimation.

The holy mode of life into which he was conducted in early years, and the fine endowments of mind which he enjoyed by nature, did not teach him the folly of vice; and he met in this world with a severe punishment, justly due to a guilty amour he indulged in at Spoleto; where he was employed at the cathedral to paint the chapel of the Blessed

Virginia. There, in his sixty-seventh year, he was poisoned by the relations of the lady whose favours he was supposed to enjoy. Lorenzo di Medici erected a marble tomb in the cathedral to his memory, which Angelo Politiano adorned with a Latin epitaph.

LIPPI FILIPPO, son of the former, was renowned for excellent imitations of architectural ornaments. He died in 1505, at the age of 45.

LIPPI LORENZO, also a Florentine painter, born in 1606. He was likewise a great musician and a poet. In the latter character he published "Il Malmantile racquillato." He died in 1664.

LIPPIA, in Botany, was so named by Houttoun, in honour of Anguine Lippi, a French botanist, as we learn from Linnaeus's *Critica Botanica*, p. 93. He is also mentioned by Boehmer, in his dissertation *de plantis in cultorum memoriam nominatis*, as having travelled into Egypt, and as having died in Abyssinia—Reliq. Houtt. 6. Linn. Gen. 322. Schreb. 396. Willd. Sp. Pl. v. 3. 356. Mart. Mill. Dict. v. 3. Michaux Boreal. Amer. v. 2. 15. Jacq. Amer. 176. Jul. 109. Lamarck Houtt. t. 539. Gærtn. t. 56.—Class and order, *Didymia Gymnospermia*. Nat. Ord. *Stelatae*, Linn. *Viticeae*, Jul.

Gen. Ch. Cal. Perianth inferior, of two distant, acuminate, keel-shaped, erect, permanent leaves. Cor. of one petal, unequal; limb divided into four segments, the upper and lower ones larger, the upper one erect. Stam. Filaments four, shorter than the corolla, two of them shorter than the rest; anthers simple. Pist. Germen superior, ovate, compressed or flattish; style thread-shaped, standing between the stamens, and of equal length; stigma oblique. Peric. none, except the permanent calyx in which the seeds are enveloped. Seeds two, adhering together, ovate, somewhat bony, convex on one side, rather smooth, flat on the other side, or somewhat concave, whitish.

Eff. Ch. Calyx four-toothed, two-valved when mature. Corolla funnel-shaped, four-cleft. Seeds enveloped in the calyx.

1. *L. americana*. Linn. Sp. Pl. 883. Reliq. Houtt. t. 12.—Heads of flowers forming a pyramid. Leaves ovate, serrated.—Found by Dr. Houttoun at Vera Cruz, and cultivated by Mr. Miller before 1733.—This is a shrub which rises to a considerable height. Stems round, compressed at their joints. Leaves lanceolate, ovate, rugged. Flowers forming little oblong heads, about the size of a large pea.

2. *L. hemisphaerica*. Linn. Sp. Pl. 883. Jacq. Amer. t. 179. f. 100.—Heads of flowers hemispherical. Leaves oblong, entire.—A native of South America.—Stems eight or ten feet high. Branches woody, bending down unless supported. Leaves opposite, two or three inches long, smooth. Flowers small and white. The whole shrub is odorous and aromatic.

3. *L. hirsuta*. Linn. Suppl. 238. Willd. n. 2. (*L. umbellata*; Willd. n. 4. Cavan. Ic. 75. t. 174.)—Heads of flowers ovate. Leaves oblong, broad, serrated, downy beneath.—A native of Mexico and other parts of America.—Stem four-sided, rough with white hairs. Leaves opposite, long, hairy above, downy and hoary beneath. Flowers small.

From examining the Linnaean specimen of *L. hirsuta*, sent originally by Escallon, a pupil of Mutis, we are enabled to state that *L. umbellata* of Willdenow and Cavanilles is not a distinct species. The flowers of that are said to be of a deep yellow, and we find those of *hirsuta* tinged with the same colour, in a dried state. As the younger Linnaeus saw

it in no other condition, he appears to have guessed them to be white, but erroneously.

4. *L. cymosa*. Willd. n. 5. Swartz. Prod. 93. Ind. Occ. v. 2. 1066. (*Spiræa* congener, spinosa, &c. Sloan. Jam. v. 2. 30. t. 174. f. 3 and 4.)—Flowers in cymes. Leaves ovate, acute, nearly entire.—A native of woody savannahs, in the southern parts of Jamaica, flowering in May.—Stems several from three to six feet high, about the size of a goose-quill. Leaves almost round, yellowish-green, smooth, scented like those of Penny-Royal. Flowers many together, of the colour and somewhat resembling those of *Spiræa Theophrasti*.

L. ovata. Linn. Syst. Veg. ed. 14. 574. Mant. 89, is properly referred by l'Heritier and Willdenow to *Sclægo*.—Michaux places *Verbena Nodiflora* of Linnaeus in *Lippia*, though with doubt, and adds another species, *L. lanceolata*, which we presume is nearly allied to *nodiflora*.

LIPPIE, a corn measure in Scotland; four lippies being equal to one peck.

LIPPITUDO, (from *lippus*, bleary-eyed.) The signification of this term, in Surgery, is rather indeterminate. Cellus attaches the same meaning to it as ophthalmia. Lippitude, or blearedness, according to Wiseman, is a state of the eyes, in which they are dimmed with rheum. We believe that, at present, surgeons generally understand by lippitudo a chronic inflammation of the ciliary glands, and of the edges and inside of the eye-lids, attended with a secretion of viscid matter, by which the eye-lids are glued together during sleep, and cannot be opened in the morning without trouble, pain, and a copious emission of tears. The case is frequently accompanied by more or less inflammation of the conjunctiva, and always by a weak impaired sight. In bad cases, the margins of the eye-lids are itudded with little ulcerations; the eye-lashes fall off; and either an entropium or an ectropium taking place, the disease is rendered more complicated.

One of the best remedies for lippitudo is the unguentum hydrargyri nitrati, a small quantity of which is to be applied once or twice every day to the edges and inner surfaces of the eye-lids. Care is to be taken that these parts are well smeared with the ointment, which should be melted in a spoon, and applied by means of a camel-hair pencil. Several other ointments will answer the purpose, particularly such as contain hydrargyrum nitratus ruber, tutty, Armenian bole, &c.; but that above recommended will always answer when others will, and very often succeeds when they will not. The effect of the ointment may frequently be advantageously promoted, by washing the eye several times a day with a collyrium, composed of rose-water ʒviij and zincum vitriolatum, from gr. x to gr. xx, according to the sensibility of the organ.

Writers on surgery mention cases of disease of the ciliary glands, which are said to depend upon scorfula, a scorbutic habit, and the venereal disease. We cannot vouch for the accuracy of this statement, but we think it certain that numerous instances are kept up by constitutional causes, which prevent the efficacy of local applications and simple methods, and often create a necessity for resorting to internal as well as external treatment. In the examples alluded to, it was justly remarked by Mr. Warner, that the ordinary means will fail unless assisted by proper regimen in diet, and alteratives of different kinds, such as calomel, Plummer's pills, extractum cicuta, alkaline absorbents, decoctions of the woods prepared in lime-water, or common water, bark, vinum antimoniale, &c. Colliveneſs is at all times to be prevented. Warner also approves of applying, in certain cases, blisters to the head, neck, or betwixt the shoulders. He thought that they acted not only as stimulants and evac-

uants,

erants, but as alteratives, by the cantharides being freely absorbed into the circulation. He was likewise an advocate for issues. See *Descript. of the Human Eye, and its principal Diseases*, by J. Warner, F.R.S. p. 13.

LIPPOMAN, LEWIS, in *Biography*, a learned Italian prelate, descended from a noble Venetian family, flourished in the sixteenth century, but the time of his birth is not known. Being intended for the church, he pursued his studies with so much diligence and success, that he was considered one of the ablest divines of his time: he was likewise distinguished for his capacity for business. He acquired considerable reputation by his attendance at the council of Trent, and was fixed on by pope Julius III. as one of the three presidents of that council. He went as nuncio into Germany, and was afterwards sent in the same high capacity into Poland, by pope Paul IV. who made him his secretary. In Poland he was the unrelenting persecutor of the Jews and Protestants; and by his zeal in defence of his own religion, he obtained, successively, the bishoprics of Verona, Modena, and Bergamo. As a writer he published "Catenas" of the Greek and Latin fathers, upon "Genesis," "Exodus," and the "First Ten Psalms." He made also a new collection of "The Lives of the Saints," in eight vols. folio. He died in 1559, and is mentioned by De Thou as one equally illustrious for the purity of his principles, and the innocence of his life. Moreri.

LIPPSPRING, in *Geography*, a town of Westphalia, in the bishopric of Paderborn, at the source of the Lippe; rendered famous by Charlemagne's obliging the Saxons to embrace Christianity in this place, and holding in it three councils; four miles N. of Paderborn.

LIPRAZZO, a town of Naples, in Capitanata; 17 miles W.S.W. of Manfredonia.

LIPS, LABIA, in *Anatomy*, the edge, or exterior part, of the mouth; or that muculous extremity which shuts and covers the mouth, both above and below. See *DEGLUTITION* and *LIP*.

LIPS are also used to signify the two edges of a wound.

LIPS, in *Geography*, a town and castle of Hungary; four miles N. of Neufol.

LIPSE, or LIPSIUS, JUSTUS, in *Biography*, a very eminent philologist and critic, was born at a village, near Brussels, in the year 1547. He shewed an early disposition for the pursuits of literature, which was cultivated at the Jesuits' school in Cologne, whither he was sent when he was about 12 years of age. From thence he went to Louvain, and engaged in the study of the civil law, still retaining a strong predilection for the belles lettres. His first work was entitled "Variarum Lectionum Libri Tres," which he dedicated to the cardinal Granvelle, who patronized him, and received him into his house at Rome, where he arrived when he was twenty years of age. He spent two years with the cardinal in the quality of Latin secretary, and employed every leisure hour in collating MSS. in the Vatican and other libraries, and cultivating an acquaintance with the eminent scholars then residing in the metropolis. On his return to Louvain he passed some time in youthful gaieties, but becoming sensible of the danger of dissipated habits, he resolved to quit the scene, and visit Vienna. In 1572 he accepted the professorship of history at Jena, though a Lutheran university: he quitted Jena in two years and went to Cologne, where he wrote his "Antiquæ Lectiones," consisting chiefly of emendations of Plautus; and at the same period began his notes upon Tacitus. After this he went to Louvain, and was created a doctor of laws: from thence he proceeded to Leyden, accepted the professorship of history, and exchanged the Roman Catholic religion for

that of Calvinism. Here he spent thirteen of the most valuable years of his life, and obtained much reputation by the works which he published. These were upon various topics, critical, historical, and philosophical: but his commentaries upon Tacitus were particularly esteemed by the learned. In two of his works, viz. "Politicorum Libri VI." and "De una Religione," he openly maintained the maxims that no state ought to permit a plurality of religions, but ought to exercise the utmost severity against all those who dissent from the church. Such sentiments, carried to the extent in which he carried them, gave great offence to the government of this country, and he was glad to withdraw into Flanders for safety. There he abjured the Protestants, and joined the Catholics, with whom he lived the remainder of his life. He settled again at Louvain, and taught the belles lettres with great success: he received liberal proposals from various sovereigns and other persons of distinction to reside under their protection, but preferred to continue at Louvain, where he published several works, some of which were not only of inferior merit, but displayed the weakness of a very superstitious mind; he did not scruple to give an account of the wonders and miracles performed at the shrine of two images of the Virgin Mary: in this he adopted every puerile and absurd tale that he found current among the vulgar. Lipsius died at Louvain in 1606, in his fifty-ninth year. His works have been collected in six volumes folio, divided, according to their subjects, into sacred history, Roman and foreign history, political and moral discussions, &c. He was a very able Latin scholar, and wrote commentaries upon Plautus, Tacitus, Valerius Maximus, Valerius Paterculus, and Seneca. Moreri. Bayle.

LIPSK, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 28 miles W.S.W. of Stuck.—Also, a town of Poland, in the palatinate of Sandomirz; 30 miles N. of Sandomirz.

LIPSO, an island in the Grecian Archipelago, about eight miles in circumference; six miles S.S.E. of Patmos. N. lat. 37° 24'. E. long. 26° 23'.

LIPTOTES, in *Rhetoric*, a figure, wherein, by denying the contrary of what we intend, more is signified than we would seem to express. Thus in the following verse of Virgil.

"Quid prodest, quod me ipse animo non spernis, Amynta."

See Vossius, *Rhet. lib. iv. p. 183.*

LIPYRIA, in *Ancient Medicine*, λυπυρία, a term applied to those varieties of continued fever, in which a burning heat was felt in the viscera, while the extremities and external parts were cold. It was ascribed by Galen and Aëtius to an erysipelatous inflammation of some of the abdominal or thoracic viscera. See Galen, *Comment. 2. in Prog. & Com. ad Aph. 48. lib. iv.*—Aët. *Tetrab. 2. lib. ii. cap. 89.*—Also Föëst *Æconom. Hippocrates.*

LIQUAMEN PYRITICUM, in *Natural History*, a name given by some authors to the liquid matter remaining in the pans in which the common vitriol is made; after which no more of that salt will shoot. It is otherwise called liquamen of vitriol.

LIQUAMUMIA, a term invented by some of the diffusatory writers, to signify human fat.

LIQUEFACTION, an operation, by which a solid body is reduced into a liquid; or the action of fire or heat on fat, and other fusible bodies, which puts their parts into a mutual intestine motion.

The liquefaction of wax, &c. is performed by a moderate heat, that of sal tartari, by the mere moisture of the air.

All salts liquefy; sand, mixed with alkalis, becomes liquefied.

quiesced by a reverberatory fire, in the making of glass. In speaking of metals, instead of liquefaction, we ordinarily use the word *fusion*.

LIQUET. See **NON LIQUET.**

LIQUID, a body which has the property of fluidity; and, besides that, a peculiar quality of wetting other bodies immersed in it, arising from some configuration of its particles, which disposes them to adhere to the surfaces of bodies contiguous to them. See **FLUID** and **LIQUIDITY**.

LIQUIDS, *Density of.* See **DENSITY**.

LIQUID alum, *amber, confects, laudanum, measures, storax, sulphur.* See the respective substantives.

LIQUID, among *Grammarians*, is a name applied to certain consonants opposed to mutes.

L, m, n, and **r**, are liquids. See **L, M, N, &c.**

LIQUIDAMBAR, in *Botany*, from *liquidum*, fluid, and *ambar*, a fragrant substance, generally taken for amber-grife; alluding to the aromatic liquid gum which distills from this tree. Linn. Gen. 499. Schreb. 649. Willd. Sp. Pl. v. 4. 475. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 365. Juss. 410. Lamarck Illustr. t. 783. Gærtn. t. 90. Michaux Boreal-Amer. v. 2. 202.—Class and order, *Menocia Polyandria*. Nat. Ord. *Amentacea*, Linn. Juss.

Gen. Ch. Male flowers numerous, in a long, conical, loose catkin. *Cal.* a common involucre of four ovate, concave, deciduous leaves, the alternate ones smaller. *Cor.* none. *Stam.* Filaments numerous, very short, in a mass which is convex on one side, flat on the other; anthers erect, of two lobes and two cells, with four furrows.

Female flowers collected into a globe, at the base of the male catkin. *Cal.* an involucre, as in the male, but double, the proper perianths being several within it, connected together, bell-shaped, angular, warty. *Cor.* none. *Pist.* Germens two, superior, united to the perianth and to each other; style to each solitary, long, awl-shaped; stigma recurved, downy. *Peric.* Capsules two, coriaceous, beaked, of one cell, opening at the inner edge. *Seeds* several, oblong, compressed, shining, with a membranous point.

Eff. Ch. Male, Catkin with a four-leaved involucre. Corolla none. Stamens numerous.

Female, Catkin globose, with a four-leaved involucre. Perianth of one leaf, pitcher-shaped, two-flowered. Corolla none. Styles two. Capsules two, surrounded by the perianth at their base, each of one cell, with many seeds.

1. *L. styraciflua*. Maple-leaved Liquid-amber, or Sweet Gum. Linn. Sp. Pl. 1418. Duhamel Arb. v. 1. 366. n. 1. t. 139. Sm. Inf. of Georgia, t. 48. Ehrh. Pl. Off. 129.—Leaves palmate, serrated, acute; veins hairy at the base of their ramifications.—Native of swampy ground in most parts of North America, near rivulets. It is a tall, straight, and handsome tree, with a round head of alternate, stalked, elegant and shining leaves, palmate like some kinds of maple, smaller than those of the Plane. *Flowers* terminal; the male a stalked, hairy, branched, conical catkin, or rather perhaps a cluster of globose flowers, nearly a finger's length; female a globular head, on a long simple bracteated stalk, springing from the base of the former. *Fruit* smaller than that of the Plane, beset in every direction with the long prominent points of the capsules. This tree is hardy in our gardens, and very ornamental, changing in autumn to various rich hues of red and orange, but does not blossom in Europe, at least not till it is very old. The gum, which exudes from any wounds in the trunk, in the warmer parts of its native climate, is seldom produced here. We have once collected it from a tree in Kew garden. Its scent is very fragrant and agreeable, like Benzoin or Storax.

2. *L. imberbis*. Oriental Liquid-amber. (*L. orientalis*; Mill. Dict. ed. 8. n. 2. *Platanus orientalis*; Pocock's Travels, v. 2. t. 89. Willd.)—Leaves palmate, bluntly crenate, or wavy, obtuse; veins naked.—Native of the Levant. Seeds were sent to France by Peyssonel, and some were forwarded to Miller, who raised plants from them at Chelsea. Whether any of these trees exist in England at present we know not. Some were to be seen at Paris 25 years ago, and probably still remain. This species differs from the former in having smaller leaves, whose lobes, as well as their notches, are all blunt, their margins wavy, not serrated, and their veins nearly or quite destitute of all pubescence at their origin.

For *L. asplenifolium* of Linnæus, a name which he afterwards changed, much for the worse, to *peregrinum*, see **COMPTONIA**.

LIQUIDAMBAR, in *Gardening*, comprises plants of the hardy deciduous tree kind, of which the species cultivated are the maple-leaved liquidambar, or sweet gum (*L. styraciflua*;) and the oriental liquidambar (*L. imberbis*.)

Method of Culture.—These two plants are increased by seeds and layers. In the former mode the seed should be sown as soon as it is procured from abroad, in spring, in a bed of light earth, half an inch deep, when the plants will rise some the same year and others not until the spring following, moderate waterings being occasionally given, keeping them clean from weeds all summer, and protecting them from severe frost the first two winters. When the plants are two years old, plant them out in spring, in nursery rows, two feet asunder, to remain three or four years, or till wanted for planting in the shrubbery, and other places. But some sow the seeds in pots, or boxes, in order to move them to different situations as the season requires; and when the plants do not come up the same year, the pots may be plunged in a hot-bed in the following spring, to forward their rising.

In the latter, or layer method, the layers should be made from the young shoots of the preceding summer, by slit-laying, when most of them will be rooted in the following autumn, though, in a dry poor soil, they are sometimes two years before they are sufficiently rooted for being removed to plant out.

These trees have great merit for ornamenting shrubbery plantations, in assemblage with others of similar growths, being handsome, straight-growing trees, with fine heads, as well as adapted for planting detached as single objects, in spacious short grass openings, in which they appear very ornamental, perfuming the air all round in the summer months. They succeed in any common soil and situation, and endure the severest cold without injury. They are usually kept in the nurseries for sale.

LIQUIDATE an *Action*. See **ACTION**.

LIQUIDATION, the act of reducing and ascertaining either some dubious disputable sum, or the respective pretensions which two persons may have to the same sum.

LIQUIDATION, the termination or winding up of accounts, such as paying or receiving debts, &c.

LIQUIDITY, in *Chemistry*, one of the three states of bodies between the solid and the aeriform state. The liquid and elastic states of bodies have the common denomination of fluids, hence the word fluid cannot be used to express either of these states particularly. Before the improvements in modern chemistry, the same explanation was applied to account for the properties of a liquid and an elastic fluid, under the general appellation of fluid; although bodies in each of these forms are differently constituted.

LIQUIDITY.

Sir Isaac Newton and the philosophers of his time supposed, that fluidity was occasioned by the spherical form of the particles of the bodies by which they were supposed to move with facility in all directions. Since, however, the constitution of bodies in different states is better understood, such an hypothesis is not necessary. Håüy has rendered it very probable, that the particles of bodies are of the form of their primitive crystals, which are flat-sided solids of the same regular form.

When we recollect that the particles of bodies, in the most solid state in which we find them, are far from touching each other, their spherical figure would not avail in giving them fluid properties, when they are changed into that form by the agency of heat.

Since bodies are found to expand by heat, and contract when the heat is withdrawn, it seems obvious, that the particles of bodies are acted upon by two forces; the one attraction, residing in the particles of the bodies; and the other, the repulsion of the particles of caloric for each; and which being combined with the attractive particles, give them the tendency to recede from each other, at the same time that the attraction is not altered.

The equilibrium, between the two forces, is kept up by the different distances of the particles, on which the relative volumes belonging to different temperatures depend. If we gradually raise a rod of tin, or any other metal, from the common temperature to its fusing point, we first observe its progressive expansion, by which we are to infer, that the cohesive force is diminishing in some ratio of the expansion. When it has arrived at a certain temperature, the pillar of metal will lose its form, and if it were not confined by the sides, it would become extended into a sheet of a thickness proportionate to its degree of fluidity. In other words, when the cohesion of the particles is so diminished, as to be exceeded by the action of gravity upon the particles individually, the solid will assume the liquid form.

This hypothesis perfectly explains all the phenomena attendant on the liquefaction of those bodies which are not susceptible of crystallization, such as wax, resin, tallow, and several other substances. Such bodies, we observe, first begin to soften by the partial loss of cohesion, and gradually become more and more liquid, till the degree of the heat shall occasion their decomposition, or give them the elastic form.

These bodies, as we should expect, increase in volume to the point of extreme liquidity, and the solid mass is of much greater specific gravity than the liquid.

The class of bodies that are susceptible of the crystalline form, which takes place at the point of liquidity, appears to depend upon some other cause than the mere presence of caloric, and on that account will present many anomalies to the above theory. These anomalies, however, are alone obvious at the point when crystallization is taking place. In some of these bodies, such as water, we do not observe any medium between perfect solidity and almost perfect liquidity.

The solids are in general of less specific gravity than the liquids, and consequently float upon them. And it is observed, that the point of maximum density is at a higher temperature than the point of congelation. The greatest density of water is, according to the enquiries of Dalton, at 36°, the point of congelation being at 32°. If, however, a mass of water be cooled, while the vessel holding it be kept at rest, it may be reduced as low as 18°, and even 16°, without congelation, contracting in volume all the time. When, however, the vessel is agitated by giving a tremulous motion to the table, the whole becomes instantly solid, with

a certain degree of expansion, and the temperature rises to 32° at the same moment of time. It would therefore seem, that the contraction and expansion by the presence or absence of caloric would be perfectly consonant with the change of temperature, were it not for the interference of this mysterious law of crystallization.

The circumstances under which the congelation of crystalline bodies takes place, clearly shews that something more is wanting than the mere abstraction of caloric. Salts are found to crystallize by standing for a certain time, although the temperature and quantity of water remain the same. It would therefore appear, that the integrant particles require time to arrange themselves; and that the salted form, as well as their regular form, is dependent on their arrangement: or that attraction of aggregation is the greatest when the integrant particles are placed in one particular direction. And it appears, since the strongest aggregation exists when the crystals are best formed, that the attraction causing solidity is the greatest when the homologous sides of the particles are parallel to one another, taking it for granted, that the particles are of the form of the primitive crystal.

The idea of a polarity in the particles of bodies is not new; and, from many recent facts, does not appear very gratuitous. Bodies which are magnetic or electrical, appear to be capable of arranging themselves in such order, that their poles shall be reversed to each other, from the attractions of opposite poles. We have already a striking instance of this electrical polarity in crystals of the *tourmalin*. And from some late experiments by Malus, it appears that even the particles of light are possessed of polarity, confirming what Newton had before conjectured.

When we apply heat to a solid crystalline body, such as a piece of ice, caloric does not effect its liquefaction by removing its particles to a greater distance, because the ice is not so dense as the water; consequently, the particles are nearer in the liquid than in the solid form. It would appear, in this instance, that the caloric had the power of lessening, and perhaps destroying altogether, the polarity of the particles, an effect which is not more unlikely than that of a certain temperature destroying the polarity of a magnet.

When, however, the caloric is removed, the polarity may return, but this alone is not sufficient to render the water solid. A certain time, with a certain degree of agitation, is necessary to allow the particles to assume their most favourable position for constituting the greatest aggregation, and their greatest regularity. We also should infer, that during this change, in which much force is exerted, the particles occupy more space, by which the expansion is occasioned. Similar effects take place in the congelation of most of the metals; and it will, doubtless, be found, that the solids of all bodies will be of less specific gravity than their respective liquids, in proportion to the susceptibility of crystallization, or, if we may be allowed the expression, as the polar force of their particles.

The particles of those bodies which are not susceptible of crystallization may have little or no polarity, and hence may owe their solidification to the mere absence of caloric. Their transition from the solid to the liquid form will be gradual and slow, and their hardness will be inversely as the caloric they contain. This is not the case with crystalline bodies; their transition from the liquid to the solid form is governed by several circumstances, and their hardness is not immediately in the inverse ratio of their caloric, but more dependent upon their polar arrangement. In all probability, if it were not for this latter cause, the point of congelation would be much lower in the thermometrical scale. What we termed confused crystallization, may be

a state of solidity in which the poles of the particles are deranged.

The want of fluidity in liquids may depend upon two causes. In the liquids which are homogeneous, the fluidity will be more or less perfect, according to the temperature by which the attraction of cohesion becomes greater or less. In fluids which are liable to change in their properties by exposure to the air, the want of fluidity arises from a substance being formed which is less fluid. This is the case with oils, both the fixed and volatile: such fluids are said to be tenacious. That the particles of liquids have still considerable attraction for each other, is apparent from a fluid assuming the form of drops. The drops will be more or less spherical according to the fluidity, and the size of the globules will be inversely as the density of the fluid. Hence we see the drops of sulphuric acid smaller than those of water, and the drops of mercury still smaller.

That the attraction of the particles of liquids becomes less according to temperature, is obvious from the law of their expansion. It is found that the increments of expansion are greater than the increments of heat. Mr. Dalton is of opinion, that the expansion of liquids is as the square of the temperature, and has proposed a new division of the thermometrical scale agreeably to this law. The same law that obtains in liquids which are susceptible of crystallization, will not probably hold good in other fluids, in which there does not appear to be any quick transition from solidity to liquidity. In order that the expansion may be in the duplicate ratio of the temperature, it would be necessary that the attraction should diminish in an equal degree with the increase of caloric. If the caloric, at the different points of time, be 1, 2, 3, &c. the attractions at the corresponding points should be $1, \frac{1}{2}, \frac{1}{3},$ &c. so that being inverted and multiplied into the increments of heat, they will make the increments of expansion a series of squares. The same law, according to Dalton, does not obtain in the expansions of solids and elastic fluids. A series of experiments, which would settle finally the relations between the increments of expansion and temperature, in different bodies, would be of great importance.

LIQUOR. See **DRINK, FLUID, &c.**

LIQUOR Amnii, in *Midwifery*, a clear pellucid fluid, or lymph, contained in the amnios, or inner membrane of the bag investing the fetus while in the uterus. The quantity varies very much in different women, or in the same woman in different pregnancies. In some women, when at their full term of gestation, there is not more of this fluid than three or four ounces, more commonly there are eight, ten, or twelve ounces; and in some rare cases, in women of a leucophlegmatic disposition, manifested by œdematous swellings of the legs, thighs, and labia pudendæ, two or three pints have been found. Its use appears to be to prevent the friction of the child against the amnios, or of the limbs of the child against each other, or against its body, which might occasion an abrasion of the cuticle, and an unnatural coalescence of the parts. Its purposes, therefore, are the same as those of the fluid found in the pericardium, and in all the cavities of the body in which any of the viscera are contained. It was thought to serve the further purpose of affording aliment to the fetus; but as children born without heads are found to be in other respects as perfect, as lively, strong, and plump as those with heads, it is evidently not necessary, at least for that purpose. See **CONCEPTION**, and **EMBRYO**.

LIQUOR Aluminis Compositus, in the *Materia Medica*. See **AQUA Aluminis Composita**.

LIQUOR Ammonia, or *Aqua Ammonia Pura*, P. L. 1787. See **AMMONIACAL Preparations**.

LIQUOR Ammonia Acetatis, *Aqua Ammonia Acetata*, P. L. 1787, is prepared by adding four pints of the acetic acid to two ounces of carbonate of ammonia, until bubbles of gas no longer arise, and then mixing. If the acid predominate, the solution is more grateful to the taste, and if the acid be correctly prepared, the proportions above stated will be sufficient; but where the strength of the acid cannot be depended upon, it will be right to regulate them by the cessation of effervescence rather than by quantity.

LIQUOR Ammonia Carbonatis, *Aqua Ammonia*, P. L. 1787. *Spiritus Salis Ammoniaci*, P. L. 1745, is formed by dissolving eight ounces of carbonate of ammonia in a pint of distilled water, and filtering the solution through paper. See **AMMONIACAL Preparations**.

LIQUOR Calcis. See **LIME-water**.

LIQUOR Cupri Ammoniaci, *Aqua Sapphirina*, P. L. 1745. See **COPPER**.

LIQUOR Ferri Alkalini. See **IRON**, in the *Materia Medica*.

LIQUOR of Flints. See **FLINTS**.

LIQUOR Hydrargyri Oxymercurialis is prepared by dissolving eight grains of the oxymercurate of mercury in fifteen fluid-ounces of distilled water, and then adding a fluid-ounce of rectified spirit. This solution is directed for the purpose of facilitating the administration of divisions of the grain of this active medicine. Each fluidrachm contains $\frac{1}{15}$ th of a grain of the salt. The spirit, though it assails, is not absolutely necessary to the solution of this quantity, but it preserves it afterwards, and prevents the vegetation of mucus, to which all saline solutions are liable.

LIQUOR Mineralis Anodynus, the same given by Hoffman to a liquor of his own invention, famous at this time in Germany, and supposed by Burgrave to be made in this manner: take oil of vitriol and Indian nitre, of each four ounces; distil the spirit gradually from this by a retort; pour two ounces of this spirit cautiously and successively into fifteen ounces of spirit of wine highly rectified; distil this, and there comes over a very fragrant spirit. This is to be again distilled, to render it perfectly pure, adding first to it a small quantity of oil of cloves, and a quantity of water, equal to that of the spirit; after this, as soon as the watery vapours begin to arise, the whole process is to be stopped, and the spirit kept alone in a bottle well stopped. This has great virtues as an anodyne, diaphoretic, antiseptic, and carminative. It is not certain that it is exactly the same with Hoffman's, that author having never published his manner of making it; but it appears the same to the smell and taste, and has the same virtues.

M. Macquer says, that it is a mixture of very rectified spirit of wine, of ether, and of a little of the sweet oil of vitriol; and that it is made by mixing an ounce of the spirit of wine, which rises first in the distillation of ether, with as much of the liquor which rises next, and which contains the ether, and afterwards by dissolving in this mixture twelve drops of the oil which rises after the ether has passed. This liquor has precisely the same virtues with the ether which physicians now substitute for it. See **ETHER**.

LIQUOR

LIQUOR Potasse. See **LIXIVUM Saponarium.**

LIQUOR Potasse Subcarbonatis. See **LIXIVUM Tartari.**

LIQUOR, or Smoking Spirit of Libavius, or Smoking Muriat of Tin, is a marine acid, or super-oxylated muriat of tin, very concentrated, smoking, and impregnated with much tin. (See **TIN**.) It is made by well mixing an amalgam of four parts of tin, and five parts of mercury with an equal weight of corrosive sublimate, by triturating the whole together in a glass mortar, or it may be prepared by melting, in an iron ladle, 5 oz. of pure tin, adding to it five drachms of mercury, stirring them together, and pouring out the amalgam into a marble mortar; and then putting 20 oz. of corrosive mercurial muriat in fine powder, and mixing the whole thoroughly. This mixture is to be put into a glass retort, which is to be placed in a reverberatory furnace. To the retort is to be luted, with fat lute, a receiver, with a small hole in it, in the same manner as is done for the distillation of concentrated mineral acids; the distillation is begun with a graduated and well managed fire; with an Argand lamp, or a sand-bath. A very smoking liquor passes into the receiver, and towards the end of the distillation a very thick and even concrete matter. When the operation is finished, the liquor in the receiver is to be poured quickly into a crystal glass bottle, with a glass stopper. When this bottle is opened, a white, copious, thick, and poignant fume issues, which remains long in the air without disappearing. (Macquer's Chem. Dict.) Proust gives, as the best proportions, 8 oz. of powder of tin (probably such as is made by melting the metal and shaking it in a box), and 24 oz. of corrosive sublimate, which afford 9 oz. of the smoking liquor. See **ETHER**.

LIQUORS, Stygian. See **STYGIAN Liquors.**

LIQUORS, Clearing of. See **CLARIFICATION.**

LIQUORICE, in Botany, Gardening, and the Materia Medica. See **GLYCYRRHIZA.**

LIQUORICE, in Agriculture, a plant of the long tap-rooted kind, often cultivated for medicinal and other uses in the field. It grows to about four or five feet in height; its stalks are hard and woody; its leaves small and roundish, standing together on the two sides of a rib, and making what botanists call a winged leaf. There are two species of this plant in cultivation, the *smooth podded* and the *prickly podded*; but they differ little, except in the seed-pods of the latter being armed with prickles. It is remarked that both these species are very hardy perennials, but that the first is the sort commonly cultivated for use, its roots being fuller of juice, and sweeter than the other.

It is chiefly grown for the root, which is perennial; but the stalks rise in spring, and decay in autumn.

It is a plant which delights in a deep light soil, in which its roots may run down three or four feet deep, and attain a large size, especially when permitted to stand three or four years. From the main root smaller ones generally run off horizontally; and from these horizontal roots, that run near the surface, cuttings for sets or young plants are taken for propagation, which are generally procured at the time when the liquorice is taken up for use, which is in about three years after planting; but cuttings for planting may occasionally be taken off before that period, if wanted. At the time of planting, the cuttings should be divided into lengths of six or eight inches, each having one or more good buds or eyes, being put into the ground at any time, in open weather, from October till March; but from the middle of February till the middle of March is the best season for this work: and an open situation is always the most proper for a plantation of this kind.

It has been long since observed, that this plant thrives

VOL. XXI.

best on a deep, loose, rich mould; and if it is fresh land that has not for many years borne corn, the profit will be the greater, as the crop will be larger, and the roots of a finer quality. A rich sandy soil, provided it is deep, will do well for this plant; and it must always be remembered, that too much moisture is its greatest enemy: let no one, therefore, attempt to plant it on a damp clay, lest the whole crop be cankered.

Soils intended for liquorice should be trenched two or three spades deep, if the depth of them will admit: then having the sets ready, proceed to plant them by line and dibble, planting the sets a foot distant in each row; putting them perpendicular into the ground, with the tops about an inch under the surface, and let the rows be a foot and a half asunder; though some scarcely allow more than twelve inches between row and row. A crop of onions is also sometimes sown on the same ground the first year; which, as the roots of the onions are slender, and the stems spread but little at top, may be done without any detriment to the liquorice or the onions, as the former seldom rises above ten or twelve inches high the first summer. The ground must be kept clean from weeds, during the summer season, by hoeing; and if there is a crop of onions, the small hoe should be employed, cutting them out to four or five inches distance, and clearing away all such as grow immediately close to the liquorice plants; and when they are gathered, give the ground a thorough hoeing with a large hoe, to loosen the surface, and destroy all weeds effectually. In autumn, cut down the decayed stalks of the liquorice, and nothing more is necessary till spring. But in February or March, a slight digging should be given between the rows; and, during spring and summer, all weeds be kept down by broad-hoeing; and in autumn, when the stalks are in a decaying state, they must be again cut down to the surface of the earth, as has been just observed. The same management must be repeated every succeeding year; but after the first or second year, the stalks of the liquorice will shoot strongly, and soon cover the ground, so as to retard the growth of weeds in a great degree. Likewise every autumn, about October, when the stalks begin to decay, and they have been cut down to the ground, as has been advised before, they should be wholly cleared away. It is remarked, that land cannot be made too fine, or dug too deep for liquorice; that it should be at least moved with the spade to the depth of two feet and a half; and if a little deeper, so much the better. And that if the land on which the liquorice sets are to be planted is fresh, rich, and in good heart, it needs no manure for the first crop; but that if it has been for some years in tillage, the planter will do well to give it, in the summer time, a good dressing of very rotten dung, lime, and coal-ashes, or soot, mixed together, some months before, into a compost: the quantity must be regulated by the state of the land, always remembering that this plant requires a great deal of nourishment, and is a great impoverisher of the soil, though it extracts much of its nourishment or food from a considerable depth.

But in another mode, after the ground has been properly prepared, and reduced to a very fine tilth, and laid level, some sets are to be procured. These are directed to be planted in rows, with dibbles armed with iron points. Some prefer rows at two feet asunder, putting the sets fifteen inches from each other, and three rows are planted on a six-foot bed; they are allowed two feet more of interval betwixt bed and bed. And in putting in sets with a dibble, the upper end of each set is left just level with the surface of the ground: and when the whole spot of ground is planted, labourers dig up the intervals one spit deep, and spread the

earth on the beds; which raises them about two inches above the heads of the sets, which, by lowering the intervals, serves in wet seasons to drain the beds. It is generally contrived to get this work done by the last week in September; but in favourable years, the middle of October is not too late. If the weather proves mild, no further trouble is taken with them during the winter; but if it is likely to freeze hard, the beds are covered with peas-haulm, or long dung, or some such matters, to forward the growth of the roots in the spring, and protect them during the winter from the frosts. Early in the spring, on the first appearance of the weeds, the liquorice is allowed a thorough hoeing; and this is several times repeated in the dry weather of the summer. The winter following, they are again covered with long dung; and in the spring, before the roots begin to shoot, the spaces betwixt the rows on the beds are loosened with a spade, and the intervals dug: immediately after which, the land has a slight dressing of coal-foot given, which is sown by hand: this should be thick enough to make the land look black, which, by the first rains washing it in, greatly pushes and invigorates the plants. The second and third summers, it is only necessary to keep the crop clear of weeds.

About the third year after planting, the roots of the liquorice will be in a state to take up; and the proper season for this is any time from the beginning of November till February, as they should neither be taken up before the stalks are fully decayed, nor deferred till late in the spring; otherwise the roots will be apt to shrink and diminish in weight.

Manner of taking up.—The mode of taking up the liquorice roots is by trenching the ground, beginning at one end, and opening a trench close to the first row three spades deep, or to the depth of the roots; at which work, three or four spademen are generally employed at each trench: one goes on with the top spit, a second with the next spit, another with a third spit, and the fourth spademan commonly gets to the bottom of the roots, having a mattock to assist him occasionally in clearing them; and, as he takes them up, throws them on the top of the ground. In this way they proceed from row to row, till the whole plantation is taken up. The small side-roots are then trimmed off, and the best of them divided into lengths proper for fresh sets, and the main roots tied in bundles for the purpose of sale. It is of much consequence to sell them as soon as possible after they are taken up, as they are apt to lose much of their weight by keeping.

After a crop of this root has been taken up, if it was planted on fresh land, the same ground is generally prepared to yield another crop; and this takes up nearly a year. In doing which, it has given it, during the winter, a thorough good dressing of well-rotted dung, mixed with lime: of this large quantities are laid on, still having regard to the condition of the soil, and ploughing it well in the ensuing summer. In such loose soils as are proper for this plant, there is no occasion to dig the land for this crop a second time, the taking up the roots having stirred it to a sufficient depth: this, with three or four summer ploughings, is as much as is necessary. In other respects, it is managed the same as for the preceding crop.

But if the land which has borne a crop of liquorice root was not fresh when it was planted, but had been some time in tillage, it is scarcely ever chosen to plant again with the same crop, without allowing several years to elapse.

After-Culture.—In whatever way this crop is cultivated, it should be kept perfectly clean by effectual hoeing in May and June; and for this reason it is better not to sow onions,

or any other small plants, upon the land with this sort of plants. In the liquorice husbandry, the land should likewise be very highly manured, and be kept well water-furrowed for the spring months.

In order to discover how much liquorice-root is watted by being kept in dry places, a choice was made of a piece of single root thirteen inches long, and full three-fourths of an inch diameter throughout, which weighed five ounces; and nine small roots, thirteen inches long each, and from one-fourth to one-eighth of an inch in diameter, which weighed also five ounces. All these were put into a drawer in a dry room, the beginning of February, and were weighed the beginning of August following; when the largest single root weighed two ounces and three quarters, and the nine small roots also weighed full two ounces and three quarters: so that in six months these roots lost almost half their weight. They were green and juicy when put into the drawer, and were now pretty dry and hard; but not quite so dry and hard as some of the same liquorice that had lain all that time in the open room. But liquorice may be kept in moist sand, or laid in the earth as long, with very little waste or loss of weight.

As liquorice is an upright growing plant, and not apt to lodge, and its roots descending deep, it is very proper for the horse-hoeing culture; in which it will probably arrive to greater perfection than in the usual method of cultivating it, as described above.

However in Yorkshire, where liquorice is cultivated in rich sandy soils, its roots sometimes penetrate to the depth of three or four feet, sometimes more; but the digging of the ground all over to that depth, when it is taken up, is very expensive. As a saving in this respect, the planters, in digging up the ground, lay it in a proper form, and replant it, making one digging serve for both purposes, which is a good method; but they set the plants much too close: whereas, if they planted them in rows, at about four feet distance, and horse-hoed it, the weeds might be destroyed, and the land greatly improved, especially if trench-hoed; and the produce would probably be very great, after so full a preparation of the land. And in addition to this, it may be observed, that this method of cultivation is much cheaper than by hand-work, which is the usual method.

LIQUORICE *Vetch.* See *ASTRAGALUS*.

LIQUORICE *Vetch, Knobbed-rooted.* See *GLYCINE*.

LIQUORICE, *Wild.* See *ABRUS*.

LIRA, or LIRE, a money of account in Italy, and also a silver coin, particularly at Milan and Venice.

LIRELLA, the diminutive of *lira*, a ridge or furrow, is used by Acharius for the peculiar fructification, or receptacle, of the genus *Opegrapha*. (See *LICHENES*.) Its colour is generally very black, though sometimes hoary with a sort of efflorescence; its form oblong, sessile or immersed, simple, aggregate or branched. The disk is usually narrow and linear, occasionally somewhat dilated; the margins parallel, various in thickness and elevation. In English this receptacle is termed a *cleft*.

LIRIA, or LLIRIA, in *Ancient Geography*, a town of Spain, in the province of Valencia; 18 miles S. of Segorbe. This is a very ancient town, which is said to have existed before the arrival of the Phœnicians in Spain. Under the Carthaginians it bore the name of Edera, and under the Romans of Edeta and of Laurona, when it was the capital of the country of the Edetani. There are some Roman monuments remaining. The town was almost destroyed during the wars of Sertorius and Pompey; but being afterwards rebuilt, it was taken by the Goths from the Romans, from the Goths by the Moors, and from them, in 1252, by

James

James the Conqueror, king of Aragon, who somewhat changed its position.

It is situated between two little hills: it has a parish church, two chapels of ease, two convents of Trinitarian and Franciscan monks, and a population of about six or seven thousand persons. This town has the title of duchy. King Philip V. gave it to marshal Berwick, and his descendants still possess it.

LIRIODENDRUM, in *Botany*, from *λίριον*, or *λίριος*, a lily, and *δένδρον*, a tree; the Tulip-tree. Linn. Gen. 278. Schreb. 373. Willd. Sp. Pl. v. 2. 1254. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 329. Juss. 281. Lamarck Illustr. 491. Michaux Boreal-Amer. v. 1. 326. Gærtn. t. 178.—Class and order, *Polyandria Polygynia*. Nat. Ord. *Coadunate*, Linn. *Magnolia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of three oblong, obtuse, concave, spreading, equal, petal-like, deciduous leaves. *Cor.* bell-shaped, regular, of six oblong, obtuse, equal petals, concave at the base. *Stam.* Filaments numerous, inserted into a conical receptacle, shorter than the corolla, linear; anthers terminal, longer than the filaments, but still shorter than the corolla, linear, erect, of two cells, bursting longitudinally at the outer side. *Pist.* Germens numerous, disposed in the form of a cone; styles none; stigmas all crowded together, obtuse. *Peric.* Cases numerous, imbricated in the form of a cone, lanceolate, compressed, leaf-like, triangular and tumid at the base, each of one cell, not bursting. *Seeds* two, ovate.

Eff. Ch. Calyx of three leaves. Petals six. Anthers bursting outwardly. Seed-cases lanceolate, imbricated in the form of a cone.

1. *L. tulipifera*. American Tulip-tree. Linn. Sp. Pl. 755. Curt. Mag. t. 275. Sm. Inf. of Georgia, t. 102. (*L. foliis angulatis truncatis*; Trew Ehret, t. 10.)—Leaves lobed, abrupt.—Native of hills in moist parts of North America, where it is vulgarly called the Poplar. This fine tree was cultivated by bishop Compton, at Fulham, in 1688, and is now not unfrequent in England, though seldom flowering till an advanced age. We have however known it bloom when about 16 years old. The first which produced blossoms in this country, is said to have been at the earl of Peterborough's, at Parson's green, near Fulham. There were several, early celebrated for their size and beauty, at Waltham Abbey, one of which remained lately, and perhaps still flourishes.

Botanists indicate two varieties in North America, one of which is figured in Plukenet's *Phytographia*, t. 68. f. 3, and appears to differ from the common kind, represented in the plates we have quoted above, in having four slight lobes, instead of two great ones, at each side of the leaf. We have indeed observed the leaves to have occasionally divided side-lobes, in our gardens; but as there are said to be differences also in the colour and quality of the wood, it is much to be suspected that these make in fact two species. In some trees the wood is said to be yellow, soft and brittle; in others white, heavy, tough and hard; but no one has observed whether each particular variety has either form of leaf appropriated to it, which would settle the question. The remarkable shape of the leaves of the Tulip-tree, cannot fail to strike the most careless observer. They seem as if cut off with scissars at the end. The elliptical obtuse deciduous *stipulas*, which curiously unfold the young leaves, are also remarkable. The flowers, though not glaring nor scented, are singularly beautiful, resembling a small tulip, variegated with green, yellow, and orange. They appear in

June and July, standing solitary at the ends of the branches. The young bark of this tree is very aromatic.

2. *L. liliifera*. Indian Tulip-tree. Linn. Sp. Pl. 755. (*Sampacca montana*; Rumph. Amboin. v. 2. 204. t. 69.)—Leaves lanceolate.—Native of lofty mountains in Amboyna. Linnaeus adopted this species entirely from Rumphius, led, as it seems, by his delineation of the fruit, which indeed somewhat resembles that of a *Liriodendrum*. There is much in his description, as well as figure, that accords with *Magnolia pumila*, Andr. Repof. t. 226. Curt. Mag. t. 977, a plant cultivated in various parts of the East Indies, as well as in China, but whose native country, like the structure of its fruit, is really unknown. M. Correa de Serra, whose botanical acuteness is so well known, has pointed out to us what he conceives to be a certain criterion to distinguish a *Liriodendron* from a *Magnolia*, the cells of the anthers opening at the inner side in the latter, at the outer side in the former, which difference is confirmed by the total difference in their fruit. By this rule the *pumila* is a *Magnolia*; but respecting the supposed *Liriodendrum liliifera*, nothing can be guessed, except from its habit. We suspect moreover that the *pumila*, when its fruit is known, may exhibit characters in that part, sufficient to separate it from both these genera; as may also be the case with *M. fuscata*, Ait. Hort. Kew. v. 3. 331. Andr. Repof. t. 229. Curt. Mag. t. 1008, whose anthers likewise burst inwardly.

What the *L. liliifera* of Loureiro, Cocbinch. 346, may be, is very doubtful. He describes the anthers as opening by a terminal pore.—Here then may be another distinct genus. The flowers are said to be large, pale and scentless. Seeds imbricated in the form of a cone. He describes two more, which Willdenow has adopted from the German edition of his book, as we guess from the misquotation of pages. These are named 1, *L. Figo*, which has a singled-leaved spathaceous calyx, and a pale flower, dotted with red; and 2, *L. Coco*, which has a three-leaved calyx, and large, very white, sweet flower. Both are cultivated at Macao and Canton. The description of their fruits is like that of the genus before us, but we much doubt their belonging really to it. Nothing, in short, requires more investigation than the genera of this tribe, because scientific botanists had very little opportunity of seeing their whole fructification. We would recommend the consideration of their anthers and seed-vessels. The calyx is perhaps of less importance, except for specific distinctions.

LIRIODENDRUM, in *Gardening*, comprises a plant of the hardy deciduous ornamental kind, of which the species cultivated is the common tulip-tree, *L. tulipifera*.

Method of Culture.—Plants of this kind may be raised by sowing the seeds, imported annually from America by the seed-dealers, in spring, either in the full ground, in beds of rich light earth, in a warm situation, placing the seed lengthwise, and covering it nearly an inch deep; or in pots or boxes, plunging them in a gentle hot-bed. When the young plants appear they should be well screened from the sun, and have free air. They usually come up the same season; when in the former method water should be given them in dry weather; and if the bed be arched over with hoops, to have occasional shade from the mid-day sun in scorching weather, it will be beneficial to the germination of the seeds and growth of the young plants; continuing the waterings with care occasionally during the summer; and in winter, sheltering them with mats in frosty weather to preserve their tops, which are sometimes a little tender the first year, and apt to suffer in this way.

When the plants are two years old, they should be set out

in spring in nursery rows, two feet distant, and a foot asunder in the rows; to remain a few years, till from three to six or eight feet high, when they may be planted where they are to remain.

But they are raised best in the open ground, where the beds are prepared of good mellow rich earth, blended with old rotten cow-dung, lifting over the seeds fine turf-mould, mixed with fine sea or pit-land. And they succeed best afterwards in a light soil, not too dry. They should have their roots and branches as little pruned as possible.

This is a plant that grows so large as to become a tree of the first magnitude in its native situation, and it is generally known by the title of poplar: of late there have been great numbers raised from seeds in this country, so that they are become common in the nurseries, and there are many of the trees in different parts which annually produce flowers.

At Allerton-hall, the seat of William Roscoe, esq. there is a very large tree of this kind which flowers well.

These trees are highly ornamental in large plantations, among others of similar growth, and have a fine effect when planted out singly in large openings, kept in short grafts, in pleasure grounds, or other situations, when they flower in any full manner.

LIRIOPE, in *Botany*, a genus dedicated by Loureiro to the mother of Narcissus; a plant of the same natural family having been destined to commemorate her son. The blue colour of the present flower is thought also, by this author, to accord with the epithet *Carula Liriope*; see Ovid's *Metamorphosis*, lib. 3. 342.—Loureir. *Cochinch.* v. 1. 200.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Spathaceae*, Linn.

Gen. Ch. *Cal.* Sheath ovate, incurved, single-flowered, small, permanent, of one leaf. *Cor.* inferior, bell-shaped, spreading, divided into six deep, oblong, reflexed, fleshy, equal segments. *Stam.* Filaments six, awl-shaped, erect, equal, shorter than the corolla, inserted into the receptacle; anthers oblong, erect. *Pist.* Germen superior, roundish; style thick, furrowed, reflexed, as long as the stamens; stigma simple. *Peric.* Berry ovate, smooth, fleshy, single-seeded. Seed ovate.

Eff. Ch. Corolla in six deep segments, inferior. Sheath ovate. Berry single-seeded.

1. *L. spicata*. Loureir. *Taé tien* of the Cochinchinese, *Mac lân* of the Chinese.—Found commonly both in rude and cultivated ground of those countries. *Roots* perennial, oblong, solid, brown *bulbs*, connected by creeping radicles. *Stem* none. *Leaves* numerous, crowded together, sword-shaped, stiff, smooth, nearly erect, a foot long. *Flower-stalk* naked, round, slender, straight, about as long as the leaves. *Flowers* spiked, rather small, of a pale blue colour, without smell.

The herb before us is said to have a cooling quality, and a decoction of its leaves is thought to strengthen the hair. We know not what to make of Loureiro's description as to referring it to any known plant.

LIRIS, in *Ancient Geography*, a river of Italy, which anciently bounded the territory of Latium towards the south. This river, called also *Clanis* and *Glanis*, and now *Garigliano*, descends from the country of the Marli towards the Apennines, or by the lake Fecinus, receives many streams in its slow progress southward, and at length loses itself in the bay of Cajeta or Gata. Towards its mouth, and at some distance from a grove consecrated to the nymph Marica, the river formed extensive marshes. Pliny observes that the waters were there hot, whence Silius Italicus gives to the

Liris the epithet sulphureous. It is related, that in the year of Rome 666, Marius, pursued by the faction of Sylla, concealed himself in these marshes, with his body under water and his head covered by reeds. The same place served also as an asylum to Varus, one of the persons proscribed by the triumvirate of Octavius, Antony, and Lepidus.

LIRIUM, in *Botany*, *λίριον* of the Greeks, is synonymous with *Lilium*, but Van Royen, in his *Flora Leydenfis Prodrromus*, retains it as the name of that genus, because he uses *Lilia* for the appellation of the natural order; and for this measure he is somewhere commended by Linnæus, under whose inspection the book was written. *Lirium* is however become entirely obsolete.

LIS, in *Geography*, a lake of Russia, in the government of Tobolsk, in the midst of an extensive morass. N. lat. 63° 5'. E. long. 99° 14'.—Also, a river of the same name, which runs into the Enisei. N. lat. 62° 20'. E. long. 90° 14'.

LIS, *Fleur de*. See *FLOWER-de-Luce*. This flower was not only borne in the ancient arms of France, but adopted by our kings till the late union with Ireland. The electoral cap, as emblematic of Hanover, and the shamrock for Ireland, have been substituted for it.

LIS, or *Li*, an itinerary measure of China, equal to 1897½ English feet: so that 192½ lis measure a mean degree of the meridian nearly; but European missionaries in China have divided the degree into 200 lis, each li making 1826 English feet.

LISARA, in *Geography*, a town of European Turkey, in the province of Albania; 52 miles S S E. of Albafano.

LISBON, **OLISIPONA** or *Olyfbona*, the metropolis of Portugal and royal residence, situated in the province of Estremadura, and forming a kind of crescent or amphitheatre, on the right bank of the Tago or Tagus, on several hills. The Portuguese compute the length of the city at two leagues; and the distance from Belem to the eastern extremity is stated by Link to be a full German mile, or about 4½ English miles. The breadth of the town is very various, often but small, and sometimes quite inconsiderable, not exceeding one street, but never much more than half a league. It formerly contained several magnificent churches, 50 colleges and convents, two elegant palaces, a castle commanding the town, and several handsome squares. It was surrounded by a single wall, on which were 77 antique towers of no great strength. On the river side it had 26 gates, and on the land side 17. The streets were narrow and dirty, and some of them very steep. The houses of the citizens were generally very mean, but those of the nobility and gentry were built with stone, and exhibited an elegant appearance. Such was the state of this city before it was almost totally destroyed by the earthquake, which happened Nov. 1, A. D. 1755. Since this catastrophe it has been built on a regular plan. The population is not easily ascertained. According to the decennial census in the year 1790, the 40 parishes of Lisbon contained 38,102 fire-places or hearths; these include the suburbs of Junqueira and Aleantara, but not the villages of Belem and Campo-Grande, though these, particularly the first, are connected with the town, being within the boundary of Lisbon. Including Belem, a market town which completely joins Junqueira, the population may be estimated, according to Link, at above 300,000, exclusive of the military. Lisbon is quite open on all sides, having neither walls nor gates, nor even any fortifications, except a small castle in the middle of the town, and a number of batteries or small forts on the river. The ground on which the city stands is very hilly, and, according to the Portuguese writers, is situated,

ated, like ancient Rome, on seven hills, but it may be more properly regarded as standing on three hills. The first begins at the bridge of Alcantara, forming the proper western limit of the town, and extending to St. Benedict's street. This hill is the highest, and much celebrated for the salubrity of its air. At the western extremity it is but little cultivated, but farther to the eastward up to its summit, forming in that direction a plain, on which stands the new monastery. In many parts it is so steep, that it is laborious to walk along the streets, and even the lower street, which runs along the river, has considerable declivities, and is much incommoded by torrents occasioned by heavy falls of rain. In this part many handsome houses are erected, intermixed with those of a meaner sort, in streets that are irregular, ill paved, and often narrow. Among these scattered houses are gardens and even corn-fields. On this hill the late queen built a church and convent, to which she was much attached. The church is handsome, but constructed in a bad taste, and overloaded with ornaments. Not far from this church is the Protestant burial ground, which is planted with cypresses and Judas trees (*cercis siliquastrum*). Beyond the houses is a pleasant plain, called Campo de Ourique, separated from the neighbouring hills by deep valleys, and used as a promenade by the lower and middling classes. The second hill is a continuation of the first, from which it is separated by a valley of no great depth; it extends from St. Benedict's street to the valley in which are three new streets built by Pombal. At the foot of the eastern side of this hill the earthquake did great damage, of which traces remain, and thus made way for the erection of several handsome houses. On this eastern declivity is the opera-house. Above the public promenade this hill rises to a considerable height, and is very steep towards the next valley. This eminence affords a very fine view; in the valley beneath appears the best part of the town; to the left are olive-gardens interpersed with many houses, monasteries, and churches; opposite is the high steep hill on which the castle stands; to the left the Tagus covered with ships. This hill is succeeded by an even valley of considerable length and breadth, which forms the broadest part of the town, which was entirely rebuilt after the earthquake of 1755. On the bank of the river is a handsome square, formerly the terrace or parade of the royal palace, 610 feet by 550. The quay, and the groups of people where the ships and boats are landing and taking in their cargoes, excite attention. The east side is formed by a large building with an arcade, terminating in a pavilion, which is used as an exchange. Opposite to it is a similar building without a pavilion. In the centre of this square, the avenues of which are unfinished, is an equestrian statue of Don Joseph in bronze, on a pedestal of stone adorned with various symbols. The three principal streets rebuilt since the earthquake, are formed by large buildings of considerable elevation and good appearance. The line that divides East and West Lisbon, which is an ecclesiastical distinction (the former belonging to the bishop of Lisbon and the latter to the patriarchate) passes through this part of the town. Near this spot is the great palace of the Inquisition. Another small square not far distant is used as a promenade, and forms a garden, with several avenues of various kinds of trees and hedges. Behind this garden are the play-house and the square used for bull-fights; and at a small distance are market places. The third hill begins with an eminence, on which is the castle of Lisbon, from which it continues, with some interruption of plains, to the eastern extremity of the town. The castle is a small fort. This part of the town consists of narrow, irregular, ill-paved streets, in which occur a few neat houses. The buildings are constructed on bad models; and even among the churches

there is not one particularly distinguished, and a constant noise of little bells and bad chimes renders them still more unpleasant. The patriarchal church is famous for the royal sepulchres which it contains. This was constructed in the year 1706 by pope Clement XI., who granted to it a chapter. The patriarch has been generally a cardinal, and its revenue is computed at 114,000*l*. Lisbon was erected into a bishopric in the 5th century, and when it was retaken from the Moors by Don Alphonso, the bishopric was re-established by pope Eugenius III.; and in the year 1370 it was erected into an archbishopric. The cathedral is a Gothic edifice, dedicated to St. Vincent, who is said to have suffered martyrdom on the cape which bears the name, and it is richly ornamented. The royal palace, which fronts the Tagus, is a large and magnificent edifice, and contains a library collected at a vast expence by John V. There are some other public buildings, which are constructed in a magnificent style. Along the river to the E. of Lisbon there is a succession of small houses and villages. To the W. Belem so nearly joins Lisbon, that their respective boundaries are not easily distinguished: and the suburb of Alcantara is only separated by a bridge over a small brook which here falls into the Tagus. This suburb is only separated by an artificial boundary from that of Junqueira, as the latter is from Belem, which is a considerable market-town, where many persons of property and tradespeople of the higher classes have houses. Formerly the royal family resided here, but the castle being burnt they removed to Quelus. (See BELEM.) Besides the church of the monastery of Hieronymites, which is in a Gothic but grand style, there are in Belem two new built and very handsome churches. Near to one of these are the botanic garden and museum, and a royal garden with a menagerie and several aviaries. Beyond Belem is a park of considerable size belonging to the prince, in which are olive-trees and broom; and the chase on the N. of the river is appropriated to the prince, but that on the S. is for the use of the public. To the N.W. appear the mountains of Cintra, which lie N.E. and S.W. The Tagus washes the foundations of the houses throughout Lisbon; being towards the eastern part about two or three leagues broad; to the W. it becomes narrower, and as far as its mouth it is only about a league broad. The river is often covered with ships, and large men of war may be opposite to the town. The scene is interesting; and the market-town called Almada, with its church on the summit of the hill, and the English hospital at the foot of it, enlivens the picture. The side of Lisbon towards the country consists entirely of hills, from which are seen only the highest edifices of the town, and the traveller arrives suddenly in the city before he is aware of it. The adjacent country, particularly on the N. and E. sides, to a considerable distance, is covered with large gardens surrounded with high walls. These gardens are called in Portuguese "*quintas*," and they generally contain plantations of orange and olive-trees, and sometimes corn-fields and even vineyards. Beyond the western part of Lisbon the country presents naked and rocky hills; but some of these are luxuriantly fertile. The hills, indeed, form the meadows of Lisbon. The soil round the city consists of lime-stone and basalt. Close to the N. side of the town is the famous aqueduct, constructed of a kind of white marble, and completed in 1738. It serves to convey water from several springs situated at a distance of three leagues, near the village of Bellas, being in some parts conducted under ground. Near the town it passes over a deep valley, and rests on several bold arches, the largest of which is 230 feet 10 inches French high, and 107 feet eight inches broad. Its pointed arches seem changed, when viewed

viewed from beneath it, into majestic vaults that re-echo every sound. The whole length of the aqueduct is 2400 feet. In the middle is a covered arch-way of seven or eight feet, where the water flows on each side through a tunnel of stone. Without this arched way and on each side is a path, where two persons can walk abreast, with a parapet. The water enters the town at a place called da Amoreira, when it divides into several other aqueducts, and supplies the fountains, which, though formed in a bad taste, are ornamental. Here the gallegos draw water in small barrels, and cry it about the streets. The water is very good, containing a portion of oxygenated calcareous earth; its sources being in lime-stone hills. The trees that grow on the N. side of Lisbon are chiefly olive and orange trees. The latter are propagated by seed and afterwards grafted. In December and January the oranges begin to turn red, and at the end of January and in February, before they are ripe and sweet, they are gathered for exportation. Toward the end of March and in April they are very good, but delicate persons will not eat them till the beginning of May; at which time they begin to be perfectly sweet and well-flavoured. One tree frequently bears 1500 oranges, and sometimes 2000, and rarely 2500. The climate of Lisbon is reckoned very salubrious. A heat equal to 96° Fahr. is not uncommon in Portugal. The medial heat is generally about 60°. From Midsummer-day to the middle of September rain is very uncommon; in November and December heavy rains with frequent storms occur. Days of perpetual silent rain are very rare; for in general it comes down in torrents. In January cold clear weather often prevails, but becomes milder in February, which is generally a very pleasant month. The days of fair weather amount to 200 in the year, and those of settled rain seldom exceed 80. In this city grates for fire are almost unknown. Ventilation and coolness are chiefly consulted; and in winter a warm cloak supplies the want of a fire. In the vicinity of Lisbon the harvest is in May, and the corn is thrashed as it is with us; but in some parts it is trodden out by horses or oxen, for which purpose a floor is made in the fields. The Portuguese live chiefly on meat and fish, but are not fond of vegetables. In Lisbon the bread is generally bad. It is usually made of wheat flour, sometimes of maize, and never of rye. Potatoes are not cultivated, but imported from England and Ireland. Both the rich and poor consume great quantities of bacalhao, of which the English export thither to the value of a million and a quarter of dollars. The Sardinha, or pilchard, is also the food and comfort of the poor. The fruits most common are oranges and grapes. In the vicinity of Lisbon is a small vineyard, that of Carcavella, or Carcavelos, yielding a peculiar grape, which gives name to the Lisbon wine or to Carcavella; a wine that is said to be generally fabricated in London. The badness of the police strikes every foreigner on entering Lisbon. The filth is suffered to lie in heaps in the streets, unless it should be washed away by the rains. The streets are rendered still more inconvenient by want of light; a host of dogs, without masters, and preying on the public, wander about like hungry wolves; and, still worse than these, an army of banditti. The society of Lisbon is dull and melancholy, especially when compared with that of large Spanish cities. The inhabitants neither walk nor ride for mere amusement; there is little luxury, nor are there any fine equipages. Many servants are kept by the higher families, but they are poorly clad and ill fed. One of the principal amusements of the rich is the Italian opera, which is supported by private individuals. The play-house is little visited by persons of condition; here no women perform; and the players are fre-

quently artisans. The place used for bull-fights is a large quadrangular edifice, surrounded with wooden balustrades and benches. In summer there are bull-fights almost every Sunday, and from twelve to fifteen beasts are killed in an afternoon: in winter this amusement entirely ceases. As to the religion of the city, Link says, that people go to masfs because they have no other walk, and that they love the ceremonies of religion as a pastime, and follow processions as they would go to an opera. Lisbon is by no means destitute of literary institutions. The first and most important is the Academy of Sciences. (See ACADEMY.) The Geographical Academy, principally pertaining to the geography of Portugal, was instituted in January, 1799. Lisbon has also public libraries; and it has also some museums, and public hospitals.

The harbour of Lisbon is spacious and deep, and by the Phœnicians, who first traded hither, was denominated "Olisippo," i. e. the Agreeable bay, whence, as some have said, was formed the appellation of Lisbon. Others have fabulously ascribed the foundation of this city to Ulysses, and hence derived its ancient name Ulyssippo. The entrance of this port is difficult and dangerous, and requires the assistance of a pilot. The trade of Lisbon is extensive; and many foreign merchants, Catholic and Protestant, reside here, as it is the grand mart of all commodities brought from Brazil and other colonies belonging to the Portuguese. N. lat. 38 42' 58". W. long. 9 4' 40".

Operas at the court of Lisbon, before the earthquake in 1755, used to be the most splendid and best performed in Europe. See PEREZ, GIZZIELLO, and GUADAGNI.

Lisbon and the whole of Portugal keep accounts in rees, or reas, 1000 of which make a milree. The crusado of exchange, or old crusado, is 400 rees, and the new crusado 480 rees; the telloon 100; the vintin, or vintim, 20 rees. Hence it appears that the milree is = $2\frac{1}{2}$ old crusados = $2\frac{1}{4}$ new ditto = 10 telloons = 50 vintins.

The coins of Portugal are gold pieces, coined before 1722, which are now 20 *per cent.* higher than their original value; so that the old dobras, coined at 20,000 rees, are worth 24,000; the Lisbonnines, or moidores, coined at 4000 rees, are worth 4800, and the halves and quarters are in proportion; but there are few of these coins in circulation. The gold coins, struck since 1722, are the dobra = 12,800 rees, the meia dobra or Joaneze = 6400 rees, the half Joaneze = 3200 rees, the dezefeis telloon = 1600, the quartinho = 1200, the oito telloon = 800, the old crusado = 400 (now scarce), and the new crusado = 480 rees. The silver coins are the new crusado = 480 rees, halves, quarters, and eighths, or pieces of 240, 120, and 60 rees, the telloons of 100, and halves of 50, and vintins of 20 rees. The copper pieces are of 10, 5, 3, and $1\frac{1}{2}$ rees.

The gold piece of 6400 rees is worth 35*s.* 11*d.* sterling. The old crusado is worth 2*s.* 3*d.*, and the milree, valued in gold, is worth 67*s.* 4*d.* sterling. The new silver crusado is worth about 2*s.* 9*d.* sterling, and the milree, valued in silver, is worth 68*s.* 3*d.* sterling. Gold is to silver as 16 to 1.

The commercial weights are the quintal = 4 arrobas, the arroba = 32lb., the pound or arrate = 2 marks, or 16 ounces, the ounce = 8 outavas; $13\frac{1}{2}$ quintals = a ton. The pound of Lisbon is = 952 Dutch ascs, or 7084*3*/₄ grains English troy weight; so that 83lb. of Lisbon = 84lb. avoirdupoise weight.

The measure for corn, salt, and other dry commodities, called moyo, is = 15 fanegas; the fanega = 4 alquieres = 8 meyoys = 16 quartos = 32 outavas = 64 mequias. The alquiere measures 675 French or 817 English cubic inches; so that 21 alquieres are nearly = 1 English quarter,

or 50 alquieres = 19 English bushels. For liquid measure, the tonelada of Lisbon is = 2 pipas, the pipa = 26 almudes = 312 canadas = 1248 quartillos. The baril is = 18 almudes. The standard gauge, at the custom-house of London, of a pipe of Lisbon is 140 gallons = 31 almudes, and the almude is $4\frac{1}{2}$ English gallons nearly. The long measures of Lisbon are the vara = 5 palmos, and the covado = 3; the palmo = 8 inches of Lisbon, or $8\frac{3}{5}$ English inches; the covado is = $26\frac{3}{5}$ English inches; the Lisbon foot is = half a covado, or $13\frac{3}{5}$ English inches; and 9 feet of Lisbon = 10 English feet. In the freight of ships, 4 chests of sugar, 4 pipes of oil, 4000lb. of tobacco, and 3000lb. of gumac, are reckoned for 1 last. Kelly's Un. Cambist. See EXCHANGE.

LISBON, a town of America, in New London county, Connecticut, lately a part of Norwich; containing two parish churches, and 1168 inhabitants.

LISBURN, a post and borough town of Ireland, in the county of Antrim, and province of Ulster, now the second in the county for size and population; but in the reign of Elizabeth only a small village, called Lisnagarvey. It lies about seven miles S. of Belfast, on the river Lagan, which separates it from the county of Down. In the reign of James I. sir Fulk Conway obtained a grant of it, and settled some English and Welsh families there. In 1641 a victory was obtained by sir George Rawdon over the rebels under sir Phelim O'Neil and others, little more than a month after the breaking out of the rebellion. In 1662 the church of Lisburn was erected into a cathedral for the united dioceses of Down and Connor, and the inhabitants had the privilege granted of sending two burgesses to parliament, although not a corporate body. These privileges were given on account of their loyalty to Charles I. and II. In 1699 a patent was granted to some French refugees for establishing a manufacture of linen in the town, to which circumstance it chiefly owes its prosperity. The virtuous conduct and civilized manners of these good people were of great advantage to it, and their skill and industry set an example to those who were concerned in the same business as they were, which soon had the effect of raising the quality of their manufacture to a degree of excellence unknown till then; and the linens and cambricks made in the neighbourhood and sold in Lisburn market, have until this day kept up their superior character. Though the vicinity of Lisburn to Belfast prevents it from being a place of much trade, there is a great deal of business done in it, in various ways. On market-days it is much frequented from the quantity of linen and other things brought to it, and it is well known as the first place to meet with oats of the best quality for feed. A few years ago a fine spire of cut stone was built to the church; and lately a steeple and cupola on the market-house. The houses of worship are, a spacious church, a Presbyterian meeting-house, a Quaker's meeting-house, a handsome Catholic chapel, and a Methodist chapel. There are also some good charitable institutions. The number of houses is 800, which at $6\frac{1}{2}$ gives a population of 5212. It is said by Carlisle to be noted for the neatness of its buildings and the urbanity of its inhabitants. It sends one member to parliament, and is 73 miles N. by E. from Dublin. Dubourdieu's Statistical Account of Antrim.

LISBURN, Cape, a cape on the W. coast of North America. N. lat. 69° 6'. W. long. 165°. — Also, a cape on the island of Spiritu Santo, one of the New Hebrides. S. lat. 15° 40' 45". E. long. 166° 57'.

LISCA-BIANCA, one of the smaller Lipari islands, near Basiluzzo. This island, as well as Bottero and Datolo, in its vicinity, is rather a rock, abounding in crusts of

fulphate of alumine, and for the most part formed of lava, whitened, and so decomposed that they are easily reducible to powder.

LISCHITZ, a town of Bohemia, in the circle of Czaflau; 8 miles N. of Czaflan.

LISCIANO, a town of Naples, in the province of Otranto; 8 miles S.E. of Tarento.

LISIANTHUS, in Botany, from *lis*, smooth, and *anthos*, a flower, in contradistinction, as one would suppose, to certain other flowers, nearly allied in many respects to this, but remarkable for some sort of fringe or hairiness, as *Menyanthes*. Yet Browne, who gave the name, does not advert to this idea; and by a slip of the pen he quotes Burmann as being the first author of it, in his *Thesaurus Zeylanicus*, 145. t. 67; whereas the plant there exhibited is called *Lysimachia*, and is *Chironia trinervia* of Linnaeus! — Browne Jam. 157. Linn. Mant. 6. Suppl. 135. Schreb. 111. Willd. Sp. Pl. v. 1. 826. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 318. Juss. 142. Lamarek Illustr. t. 107. — Class and order, *Pentandria Monogynia*. Nat. Ord. *Rotacea*, Linn. *Gentiana*, Juss.

Gen. Ch. Cal. Perianth inferior, divided, more or less deeply, into five, lanceolate or roundish, erect, permanent segments, membranous at the edge. Cor. of one petal, funnel-shaped; tube longer than the calyx, swelling upwards, contracted just above the base within the calyx; limb in five deep, lanceolate or roundish, recurved segments, much shorter than the tube. Stam. Filaments five, thread-shaped, smooth, inserted into the tube, just above its contraction, generally shorter than the limb; anthers ovate, two-lobed, incumbent. Pist. Germen superior, ovate-oblong, pointed; style thread-shaped, the length of the stamens, permanent, finally twisted; stigma compressed, of two parallel plates. Peric. Capsule ovate-oblong, pointed, of two incomplete cells and two valves, the partitions formed of the inflexed margins of the valves. Seeds numerous, minute.

Eff. Ch. Corolla funnel-shaped, inflated; its segments recurved. Stigma of two plates. Capsule oblong, imperfectly two-celled; partitions from the inflexed margins of the valves. Seeds numerous.

Fifteen species of this elegant genus, little known in England, are collected by Willdenow, of which *glaber* and *frigidus* are one and the same. Whether the rest all truly constitute one genus, may perhaps be doubted. The carinated calyx, supposed an essential mark, in those of Browne, is not found in those of Aublet, the segments of whose calyx moreover are rounded, and their corolla somewhat irregular and curved. These more accord with *L. glaber* of Linnaeus, and very correctly with his *chelonoides* found in the same neighbourhood.

The following examples will enable the reader to judge of the habit and leading characters of these different sets of species.

L. longifolius. Linn. Mant. 43. Browne Jam. 157. t. 9. f. 1. — Calyx taper-pointed, keeled. Leaves lanceolate, acute. Branches round, somewhat downy. — Native of the mountains of Jamaica, in a dry sandy soil. It forms a humble shrub, with round, opposite, more or less downy, level-topped, leafy branches. Leaves opposite, on short footstalks connected by a very short, annular, intrafoliaceous stipula; their form is variable, ovate-oblong or lanceolate, acute, entire; the surface smooth, or finely downy. Flowers on short, terminal, downy stalks, solitary, or two or three together, about an inch and a half long, of a pale delicate yellow, very elegant. Their calyx and corolla are very sharply pointed; the former strongly keeled or winged, as in many plants of the Gentian family; the stigma short and almost capitate, yet of two parallel lobes.

This

This species is said to blossom in the stove at Kew in June and July. Little or no bitterness is perceptible in the dried specimen.

L. cordifolius. Linn. Mant. 43. Browne t. 9. f. 2, is probably but a mere variety, having shorter, and perfectly heart-shaped leaves, which, in our specimen from Browne, are rather more downy, as well as the branches.

L. latifolius. Swartz. Ind. Occ. v. 1. 348. never seen by us, is not by his account very clearly distinguished from these; for *longifolius* certainly has, by no means, "very long flower-stalks, widely spreading at their divisions," which he attributes to it, but rather stalks "simply three-forked, scarcely longer than the leaves," such as he describes in his *latifolius*.

L. glaucifolius. Jacq. Coll. v. 1. 64. Ic. Rar. t. 33.—Calyx taper-pointed, as long as the tube. Leaves elliptic-oblong, sessile, glaucous, smooth. Stem round.—This seems to agree sufficiently in genus with the above, though its calyx appears not to be keeled. The root is perennial. Stems herbaceous, annual, slender, nearly simple. Flowers purplish-blue, on very long simple stalks. It blossomed with Jacquin in the stove, from July to September, but he knew not its native country.

L. alatus. Aubl. Guian. v. 1. 204. t. 80.—Leaves elliptic-oblong, tapering at each end, smooth. Stem square, winged. Segments of the calyx rounded. Corolla declining.—Gathered by Aublet in cultivated as well as waste ground in Guiana and Cayenne. One of his specimens before us has the habit of a *Chelone*. Its calyx is blunt and rounded. Corolla declining, as well as the *stamens* and *style*, and somewhat irregular. The plant is said to be bitter, and its qualities deobstruent.

L. chelonoides. Linn. Suppl. 134.—Leaves oblong, slightly confluent at the base, smooth. Stem round, without wings. Branches of the panicle racemose. Calyx rounded.—Sent to Linnaeus from Surinam, and marked No. 141. in the *Planta Surinamensis*. It is so like a *Chelone* or *Pentstemon*, that Linnaeus actually took it for such. His son afterwards referred it to *Lisiantibus*, mistaking it for the above species of Aublet, from which it differs in the round stem, destitute of wings; more elongated and racemose flowering-branches; and nearly straight regular corolla.

L. glaber. Linn. Suppl. 134. Sm. Ic. ex Herb. Linn. t. 29. (*L. frigidus*; Swartz. Ind. Occ. v. 1. 352).—Smooth. Leaves ovate, stalked, acute. Flowers somewhat corymbose. Stem square below.—Native of South America and Jamaica. A large and handsome herbaceous plant, with yellow flowers, whose corolla is regular and dilated. The segments of the calyx are indeed more rounded and obtuse in the Jamaica specimens than in those of Mutis, but we cannot think that difference essential, every other part being so alike in both. The lower portion of the stem is wanting in Mutis's specimen, which caused that part to be described as round, the branches being so, as well as in Swartz's.

L. exsertus. Swartz. Ind. Occ. v. 1. 346.—Leaves ovato-lanceolate, on longish stalks. Calyx taper-pointed. Stamens and style much longer than the corolla.—Native of the cloud-capped fumants of the Blue Mountains of Jamaica. Swartz. It is said to have been alive at Kew, but not to have flowered. The stem is shrubby. Leaves numerous, elliptic-lanceolate, tapering at each end, smooth, on slender footstalks from half an inch to an inch long. Flowers rather small, in three-forked compound panicles; remarkable for the very long, slender, projecting organs of fructification. If this species be carefully considered, it will perhaps be found to conciliate, in some measure, the differences between the discordant ones above described. Its

calyx agrees most with the former, though neither keeled nor winged; its corolla with the latter; its habit is akin to both; its *stamens* peculiar to itself.

LISICZNIK, in *Geography*, a town of Poland, in Podolia; 28 miles W. of Kamimec.

LISIEUX, a town of France, and principal place of a district, in the department of the Calvados, and before the revolution, the see of a bishop. The place contains 10,192, and the canton 28,293 inhabitants, on a territory of 260 kilometres, in 30 communes. N. lat. 49° 8' 50". E. long. 0° 13' 32".

LISIGNANO, a town of Itria; 14 miles E. S. E. of Pola.

LISKEARD, a borough and market-town in the hundred of West and county of Cornwall, England, is situated partly on rocky hills and partly in a bottom; and through this inequality of the ground, the streets have the appearance of being disposed with studied irregularity. The basements of the houses are consequently diversified; the foundations of some buildings being on a level with the chimneys of others. The church consists of three spacious aisles, and has a tower built mostly of granite; the south side of the church is ornamented with pinnacles and battlements, also of granite; but the greater part of the structure is composed of slate-stone, which likewise constitutes the foundation of the town. The town-hall is supported on granite columns, in the space between which a considerable market is held on Saturdays. Here are six annual fairs. On an eminence north of the town are the mouldering foundations of a castle, but every trace of its shape and architecture is nearly obliterated: near it is a large field, still called Caille-park; but no fragments appear of the "Chapel of our Lady," mentioned by Browne Willis to have stood therein. There is, however, a house standing at the bottom of the town, which, from its windows, gateway, and sculptured ornaments, seems to have been connected with some religious establishment. Liskeard was constituted a free borough by Richard, brother to Henry III. by charter dated June 5, 1240. Queen Elizabeth, in the year 1580, granted a charter of incorporation, by which the civil government was vested in a mayor, recorder, eight capital burgesses, and fifteen assistants, who, with the other freemen of the borough, elect two members of parliament. Liskeard is 16 miles distant from Plymouth, and 237 from London: in the year 1800 the parish was returned to parliament as containing 507 houses, and 2708 inhabitants.

In the parish of St. Cleer (to the north of Liskeard) are various Druidical and other antiquities; particularly the Hurlers, which consisted, when perfect, of three contiguous circles of upright stones from three to five feet in height; the Cheese-Wring, a natural pile of rude rocks, rising to the height of thirty-two feet; the Other Half-stone, which appears to have been the shaft of a cross which originally stood upright. To these may be added, a cromlech of great magnitude, called Trevethey-stone. St. Cleer's well, of which some remains are still extant, was in the times of ignorance and superstition esteemed a bath of sovereign virtue. South of Liskeard is St. Keyne's well, which is classed by Carew among the natural wonders of Cornwall. Of this faint, and of the well, many poetical and legendary tales are extant. The spring is arched over, and on the mould which covers this arch five large trees are growing. Beauties of England and Wales, vol. ii.

LISLAU, a town of Bohemia, in the circle of Bolestaw; six miles S. of Benatak.

LISLE, CLAUDE DE, in *Biography*, a celebrated French writer in history, was born at Lorraine in the year 1644.

He was received a member of the Jesuits' college at Pont-à-Mousson, took his degrees in law, and was admitted an advocate. Conceiving, in a very short time, a great dislike to the law, he devoted himself to the study of history and geography. For the sake of the superior advantages to be obtained in the metropolis, he removed to Paris, and applied himself to the instructions of the most distinguished professors. Having obtained a large fund of knowledge on the subjects referred to, he commenced private lecturer, and acquired such a high reputation in his profession, that he could boast of having been master to the principal nobility at the French court. M. de Lisle died at Paris in 1720, in the seventy-sixth year of his age. He was author of "An Historical Account of the Kingdom of Siam;" "A Genealogical and Historical Atlas, on engraved Plates;" "An Abridgment of Universal History, from the Creation of the World to 1714," in 7 vols. 12mo.; and several other works, one of which was "An Introduction to Geography, with a Treatise on the Sphere;" published in 1740, in the name of his eldest son. Moreri.

LISLE, WILLIAM DE, a learned French geographer, son of the preceding, was born at Paris in 1675. He discovered at a very early age a genius for geographical studies, and designed maps before he was nine years of age. In the year 1696 he published a map of the world, maps of the four quarters, as they are called, *viz.* Europe, Asia, Africa, and America, a map of Italy, one of Ancient Africa, and two globes, a celestial and terrestrial one. These performances were not only well received, but established the author's fame. In 1702 he was elected a member of the Academy of Sciences, and in 1718 he was appointed first geographer, with a pension. He was about the same time appointed geographical tutor to the young king, Lewis XV., for whose use he drew up several works, among which was a general map of the world, and another of the retreat of the ten thousand. He also gave the world "A Treatise on the Course of all the known Rivers." The reputation of M. de Lisle was now so great, that all authors of respectability who wrote on history or subjects connected with it, were desirous of embellishing them with his maps; and many sovereign princes endeavoured to tempt him to enter into their service. The emperor, Peter the Great, paid him a visit with the view of obtaining from him a knowledge of the extent and situation of his own dominions. He died in the fifty-first year of his age, while he was engaged in many useful and important works. Moreri.

LISLE, LEWIS DE, brother of the preceding, celebrated for his knowledge in astronomy, rendered some important service to the interests of science, by the hazardous journeys and voyages which he undertook to promote them. In the year 1726 he went to Russia with his brother Joseph, who had been appointed astronomer to the Academy of Sciences at Petersburg. Lewis, at this time, made excursions beyond the utmost boundaries of the immense Russian empire. He took several journeys to the coasts of the icy sea, to Lapland, and the government of Archangel, to determine the situation of the principal places by astronomical observations. He afterwards traversed a great part of Siberia, with M. Mulier and M. Gmelin, professors of the academy at Petersburg. In 1741 he proceeded alone to Kamtschatka, and went from thence to Cape Beerig, to examine the unknown northern coasts of America, and the seas between them and the Atlantic continent. He died in the same year. On account of his great merit he obtained a seat in the Academy of Sciences, and was author of some papers in the "Memoirs" of that learned body, and of the Academy of Sciences at Petersburg. Moreri.

VOL. XXI.

LISLE, JOSEPH NICHOLAS DE, younger brother of the preceding, was born at Paris in 1688. Having received a good education in the elements of learning, he attended lectures in the Mazarine college. The total eclipse of the sun which occurred in March 1706, led him to pursue with avidity mathematical learning, particularly in its application to astronomy, and he soon exhibited a surprising genius for invention, combination, and calculation. In 1709, he obtained leave to occupy the cupola of the Luxembourg palace for an observatory; he was now enabled to make a wooden quadrant, which he divided with great care, and which he found to answer his purpose in his early observations. Shortly after this, his father's numerous family made it necessary for him to endeavour to procure for himself the means of support; and in doing this he found himself obliged to render his astronomical skill subservient to the revenues of judicial astrology, for which he was not only remunerated by pecuniary presents from the regent, marshal de Noailles, and other great men, but had the grant of a pension of 600 livres. This was in the year 1715, when he was deeply engaged in calculating the tables of the moon according to the theory of sir Isaac Newton. He had, previously to this, been elected a member of the Academy of Sciences, which gave new energy to his exertions, and the memoirs of that body were in a short time enriched with his valuable reflections and dissertations. He made many observations on the spots in the sun, and was led to form from them a theory to determine the sun's rotation on his axis. In 1720 he delivered a proposal to the Academy for ascertaining in France the figure of the earth, and some years afterwards his designs relative to that object were carried into execution. In 1724, M. de Lisle paid a visit to England, obtained the notice and friendship of Newton and Halley, and was admitted a fellow of the Royal Society. In 1726, by the invitation of Catharine, empress of Russia, he went to Petersburg, to fill the post of astronomer royal in the Imperial Academy of Sciences. In this situation he occupied the house of the observatory built by Peter the Great, in which he spent nearly twenty-one years, in incessant labours for the improvement of astronomy and geography. The first series of his observations were employed in ascertaining the longitude and latitude of Petersburg, and the refractions in that northern region. After this he devoted several years to an assiduous observation of the meridional height of all the planets, and of the fixed stars of the three first magnitudes, and published memoirs illustrative of the history of astronomy, in two vols. 4to. In the year 1740, a transit of Mercury was expected, which, as it would not be visible in Europe, he was determined to travel into Asia to observe. His first observations in the climate of Siberia, were on the intenseness of the cold, which was greater than had ever been pointed out by a thermometer, or than it was conceived possible for human nature to sustain. He published a memoir on this subject in the volume of the Transactions of the French Academy for 1749. When the time for observing the transit arrived, the cloudiness of the weather totally frustrated the design of his journey. His time and labour were not however wholly lost, as he employed himself in making geographical and physical observations, and in drawing up a description of the country, which description is inserted in the eighteenth volume of Quérion's History of Travels, &c. Another fruit of his expedition into the Russian dominions, was an atlas of the country, first published in the Russian language, and afterwards in the Latin. Connected with his meteorological observations, he constructed a thermometer, which was differently graduated from those then in use: the degrees began at the heat of boiling water,

U

and

and thence increased to 150, which was the freezing point. In the year 1747, after much ill treatment on the part of the Russian government, he obtained his dismissal, left Peterburg in the month of May, and arrived in Paris in September of the same year. On his return he was appointed professor of the mathematics at the college royal, in which situation he lived to render the greatest service to the interests of science, by training up pupils worthy of such a master, among whom was the celebrated M. de la Lande. He now fitted up and furnished an observatory, in which he continued his labours, without interruption, for several years. In the year 1748, his pupil M. Monnier took a voyage to Scotland to observe an annular eclipse of the sun, which furnished an opportunity for measuring the diameter of the moon at the time when it should be entirely visible on the sun's disk. On this subject De Lisle published a large advertisement, which was reckoned a complete treatise on annular eclipses. He afterwards entered more fully on the consideration of the theory of eclipses, and he communicated a part of his researches on the subject to the Academy in 1749. He was so expert in calculations, that he made many founded on the observations of Greenwich, Berlin, Scotland, and Sweden. He published "New Charts of the Discoveries of Admiral de Fonte, or Fuente, made in 1640, and those of other navigators, Spanish, Portuguese, English, Dutch, French and Russian, in the Northern seas, with explanations." This work was presented to the public in 1750 and 1753. In the latter of these years he published a curious map of the world, in which he represented, for the benefit of astronomers impatiently waiting for the transit of Mercury over the sun, the effect of the parallaxes of Mercury in different countries, in order to point out the proper places for making such observations on the transit, as should, from the difference of their result, furnish a method of determining the distance of the sun, in a manner similar to that applied by Halley to the transit of Venus. Another work of this laborious and indefatigable philosopher, published in the Transactions of the Academy, was on the comet of 1758, which had been first discovered by a peasant in the neighbourhood of Dresden, and which was visible several months; but he was principally attentive to the one predicted by Dr. Halley, forty years before, as to make its appearance in 1759, and which was first seen in January of that year. He gave an account of his observations on that comet in the first volume of the "Mercure," for July 1759. He was afterwards assiduously engaged on the subject of the transit of Venus, which was expected in 1761, in order that he might correct the error of Halley, and thus prevent persons from undertaking long voyages for the sake of observing it, whose labours would have proved useless with respect to the object in view.

M. de Lisle had, some years previously to this, been appointed astronomical geographer to the marine, an office which had been established many years, with the express view of having a dépôt, in which might be preserved all the designs, plans, charts, &c. of the coasts of France, and of the colonies and establishments in different parts of the world, with the memoirs relating to them: to M. de Lisle's office was attached the business of collecting and arranging the plans and journals of naval captains, and to extract from them whatever might be found beneficial to the king's service in this department. His majesty now purchased, with a pension for life, all M. de Lisle's rich astronomical and geographical collections, which were added to the MSS. in the depot. In the year 1758, our author felt some symptoms of decline, and withdrew as much as he could from public life, leaving the care of his observations to M. Messier,

and obtaining from the minister the appointment of M. de la Lande for his coadjutor at the college royal. He went to reside at the abbey of St. Genevieve, where he spent much of his time in devotional exercises, and devoted the greatest part of his income to acts of benevolence and charity. In his retirement he cherished his taste for astronomy and geography, corresponded with men of science, read new works, and even selected some of his own in MS. with a view to publication. He died on the 11th of July 1768, being in the 81st year of his age. As a man of science his merits are very great, and in private life he was distinguished by unaffected piety, pure morals, undeviating integrity, and most amiable manners. Gen. Biog.

LISLE DE LA DREVETIERE, LEWIS-FRANCIS DE, a French dramatic writer, was descended from a noble family, and born in the province of Dauphiné. His friends intended him for the bar, but his own inclinations were decidedly against the profession of the law, and as his father could not support him in the style which his dissipated turn required, he was resolved to maintain himself by his talents, and began to write for the Italian theatre. In 1721 he presented for public exhibition his comedy of "Arlequin Sauvage," which was successful, and which is even now occasionally brought before the public. His "Timon le Misanthrope" acquired a much larger share of popularity: he published and brought on the stage many other pieces, chiefly of the comic cast: and he composed a tragedy entitled "Danaus," and a poem entitled "Essai sur l'Amour Propre;" which, with several other pieces, were collected in a single volume. He died in 1756, and has been described as a haughty, taciturn, and thoughtful character.

LISLE, in *Geography*. See LILLE.

LISLE, a town of France, in the department of the Dordogne; 9 miles N.W. of Périgueux.—Also, a town of France, in the department of the Yonne; 24 miles S.E. of Auxerre.

LISLE, a post-town of America, in Tioga county, New York; through which passes a branch of the Chenango, uniting with the Chenango in the S.E. corner of the township. It contains 660 inhabitants.

LISLENA, a town of Sweden, in the province of Uppland; 16 miles S.S.W. of Upsal.

LISMORE, an island of the Hebrides, in the county of Argyre, Scotland. It is situated at the mouth of the great arm of the sea called Loch-Linnhe, and extends about ten miles in length and two in breadth. The whole of this island lies on a stratum of excellent lime-stone, unfortunately rendered of little value to the inhabitants by the deficiency of fuel to burn it. Mr. Pennant says the derivation of its name is from *Liosmor*, or the great garden. According to tradition, however, it was not a garden, but a deer-forest, and as a proof of this, multitudes of stags' horns of uncommon sizes are frequently dug up in the mossy parts of it. At present there is very little wood, but the soil being fertile, the lesser vegetables shoot up with uncommon vigour. The chief productions of the ground are beans and oats. The former are mostly applied to the purposes of distillation; and the latter go to the discharge of rents, so that the inhabitants are obliged to import large quantities of meal for their subsistence. There are a considerable number of cattle reared in this island, but they are generally of very small stature. The author already mentioned thinks they must have greatly degenerated from their original growth, for he informs us that he saw the skull of an ox dug up here, which was of much larger dimensions than any now living in Great Britain. About a hundred head of the largest are exported annually. The horses bred here are extremely short-lived.

They are harnessed when only two or three years old, which practice will no doubt assist in shortening the period of their existence. Neither foxes, hares nor rats can be found in the island; otters and mice however are abundant. It contains three small lakes, two of which are famed for excellent trout, and the third for eels.

Lismore was formerly the seat of the bishop of Argyle, who was thence styled Episcopus Lismorensis. Mr. Pennant says there are no remains either of the cathedral or the bishop's palace. In the Beauties of Scotland, however, it is asserted, that vestiges of both are still to be seen. The chancel of the former is there stated to be used as the parish church, and the walls of the latter are said to be pretty entire, and distant about four miles from the cathedral. Several fortified camps can yet be discovered in different parts of the island. A Danish fort, surrounded by a deep fosse, is likewise in tolerable condition. The walls are now 17 feet high, having a gallery within, and round the area a stone seat, which Mr. Pennant supposes might have been intended as a general resting place for the chieftains and their foldiers. The church, says the same author, in conformity with his assertion that there are no remains of the cathedral, "is a mean modern building." In the church-yard several old monuments are still standing, one of which is very remarkable, as consisting of nothing more than a thick log of wood. Its antiquity must be very great, as there is no word in the Erse language to denote this kind of monument. On a rock are cut the radii of a dial, but the index is destroyed. A small basin is excavated in another rock, which was probably used by the Druids in some part of their religious ceremonies.

There is no special return of the number of inhabitants in this island, but they are reckoned to exceed 1100 souls. Pennant's Tour in Scotland. Beauties of Scotland.

LISMORE, a post-town of Ireland, on the river Blackwater, and in the county of Waterford. The bridge over the river is a fine erection of the duke of Devonshire's. The span of the principal arch is 190 feet. There are excellent salmon weirs at this place, which return a considerable profit. The appearance of Lismore from the bridge is awfully sublime and interesting. The castle is seated upon a rock, which rises in perpendicular shelves from the river to a tremendous height. The rude rocks are richly crowned with trees, whose verdant boughs in some parts embrace the placid streams, and in others ascend to shelter the ruined towers, and shade the antique windows of the fort. This venerable and extensive castle, the property of the duke of Devonshire, was built by king John, in 1185, on the ruins of the abbey of St. Carthagh. It afterwards became the episcopal residence, till Myler Megrette, bishop of the see, conveyed it to sir W. Raleigh. From sir Walter it was purchased, with the rest of his property in Ireland, by Richard Boyle, afterwards the first earl of Cork, and his youngest son, the celebrated and deservedly esteemed philosopher Robert Boyle, was born in it. It has since become the property of the duke of Devonshire, who is descended by the female line from the eldest branch of the Boyle family. In the town of Lismore are a neat court-house, in which the sessions are held, a small prison, and a very respectable inn. The church, which serves both as a parish church and as the cathedral of the bishopric, is old, and was lately in indifferent repair; it is however, according to Dr. Beaufort, spacious and handsome, and will probably be thoroughly repaired. The dean of Lismore has a peculiar jurisdiction over this, and two adjoining parishes. It has been already mentioned that St. Carthagh founded an abbey here. This was in the seventh century, and the abbey was erected into

a bishopric in 633. A number of monks repairing hither, several churches and cells were built, and these being usually the seat of any learning that existed during the middle ages, a school was soon instituted, which, for a long period, became the great resort both of natives and foreigners. In 1536, this see was united to that of Waterford, under which an account of it will be given. Before the union, Lismore returned two members to the house of commons, but this privilege has ceased. It is 101 Irish miles S.W. by S. from Dublin, and 26 N.E. from Cork. Beaufort, Robertson, &c.

LISNAKEA, a post-town of Ireland, in the county of Fermanagh; 70 miles N.E. from Dublin.

LISSA, a town of Holland; eight miles N. of Leyden.

LISSA, a town of Silesia, in the principality of Breslaw, on the Weistritz; seven miles W.N.W. of Breslaw. N. lat. 51° 7'. E. long. 16° 50'.

LISSA, anciently *Lissa*, (which see,) an island of the Adriatic, near the coast of Dalmatia, once famous for the commerce, wealth, and power of its inhabitants, is a mountainous and thinly inhabited island, 30 miles in circuit. In many parts the soil is good, but not sufficiently cultivated. In its ancient state it was in alliance with Rome, and carried on war against the kings of Illyrium; but with the decline of the Roman empire, it sunk into a successive dependence on Narenta, Lelina, and Venice. Its mountains contain marble, and are intersected by fertile valleys. It produces wine, fruits, and excellent honey. But its principal source of wealth is its fishery, particularly that of sardines. The ruins of its capital of the same name appear above the harbour, near a village of the same name. It has also a well-built populous town, called "Comisa," near the sea, on the E. side of the island, where are the ruins of the ancient city of Meo. N. lat. 43° 25'. E. long. 16° 18'.

LISSA, or *Lechno*, a town of the duchy of Warsaw; raised from the condition of a village to that of a town, by the influx of Protestants driven by persecution from Silesia, Bohemia, Moravia, and Aultria. The inhabitants carry on a good trade. In this town are a Lutheran and also a Calvinist church, and a seminary; 44 miles S.S.W. of Posen. N. lat. 51° 55'. E. long. 16° 35'.

LISSA, or *Thynnus Lyssa*, in *Ichthyology*, a name by which some authors have called the fish more usually called *gliffa*, a large sea-fish of the tunny kind.

LISSABATTA, in *Geography*, a town on the N. coast of the island of Ceram, inhabited by an assemblage of different people, which have been troublesome to the Dutch. S. lat. 2° 55'. E. long. 128° 44'.

LISSANTHE, in *Botany*, so named by Mr. R. Brown, from *λίσσω*, *smooth*, and *ανθε*, a *flower*, because of the naked and beardless limb of the corolla; that part being densely covered with hairs in *Leucopogon*, and more or less fringed or tufted in several other genera, of the same natural order, found in New Holland. Brown Prodr. Nov. Holl. v. 1. 540. Class and order, *Pentandria Monogamia*. Nat. Ord. *Epacridae*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of five equal, concave, permanent leaves, sometimes accompanied by two rather smaller ones at the base. *Cor.* of one petal, funnel-shaped; tube nearly cylindrical, generally hairy within; limb in five lanceolate, equal, spreading, beardless segments. Nectary a five-lobed gland, at the base of the germen. *Stam.* Filaments five, short, within the tube; anthers roundish, of two cells, bursting lengthwise. *Pist.* Germen superior, globular, with five slight angles; style pentagonal, rigid, shorter than the tube; stigma obtuse. *Peric.* Drupa succulent. *Nuc.* hard, of five cells.

Fil. Ch. Calyx of five or seven leaves. Corolla funnel-shaped; its limb beardless. Stamens inserted into the tube, very short. Drupa succulent. Nut hard, of five cells.

Mr. Brown defines six species of this genus, separated by him from the *Styphelia* of preceding botanists, which are disposed in three sections. They are small, rigid, upright shrubs; with scattered leaves, furrowed beneath; and rather small white flowers.

SECT. 1. *Calyx of only five leaves. Clusters axillary, of few flowers, their partial stalks furnished with a pair of bractes at the base. Tube of the corolla hairy within.*

1. *L. sapida*. "Clusters of two or three flowers, recurved. Leaves oblong-linear, sharp-pointed, revolute; white and striated beneath." Br.—Gathered by Mr. Brown near Port Jackson, New South Wales.—By the name, we presume the fruit is eatable.

2. *L. subulata*. "Clusters of four or five flowers; erect. Leaves linear-awl-shaped. Branches smooth. Fruit with ten furrows."—Gathered by Mr. Brown in the same country. The leaves are about half an inch long.

3. *L. strigosa*. (*Styphelia strigosa*; Sm. New Holl. 48.) Clusters collected towards the ends of the branches, erect, of few flowers. Leaves linear-awl-shaped. Branches downy. Drupa with five slight angles.—Sent from Port Jackson by Dr. White in 1793. Found there also, as well as in Van Diemen's land, by Mr. Brown. The stem is shrubby, rigid, finely downy, with numerous, short, crowded, leafy, lateral branches. Leaves scattered, sometimes imperfectly whorled, nearly sessile, about half an inch long, rigid, pungent, revolute; smooth, even and convex above; ribbed beneath. Clusters axillary and terminal, generally crowded about the ends of the branches, short, erect, of very few flowers, their stalk downy, with several pale, concave, fringed bractes. Calyx-leaves like the bractes. Tube of the corolla thrice as long as the calyx; limb acute, one-third the length of the tube. Anthers rising just above the mouth, accompanied by a few erect hairs from the inside of the tube. Germen and lower part of the style clothed with fine, short, hoary down.

SECT. 2. *Calyx of seven leaves. Corolla short, its tube and mouth without hairs. Spikes axillary, of few flowers.*

4. *L. montana*. "Leaves oblong-linear, obtuse, point-les; glaucous beneath."—Gathered by Mr. Brown at Van Diemen's land.

SECT. 3. *Calyx of seven leaves. Corolla elongated, its mouth beset with deflexed hairs within the tube. Flowers axillary, solitary.*

5. *L. daphnoides*. (*Styphelia daphnoides*; Sm. New Holl. 48.)—Leaves elliptic-lanceolate, slightly concave, with a blunt callous point; their edges naked, roughish. Sent from Port Jackson by Dr. White, in 1792. Mr. Brown found it both in the tropical part of New Holland, and in Van Diemen's land. The stem is much branched, leafy, and finely downy. Leaves scattered, from $\frac{1}{2}$ h to $\frac{3}{4}$ h of an inch long, very various in breadth, more or less elliptical, smooth, slightly concave, entire; minutely roughish at the edges; furnished with numerous branching ribs beneath. Flowers numerous, axillary, solitary, on short hairy stalks. Calyx-leaves all nearly of equal size and appearance, ovate, pointed, smooth, finely fringed, two of them external. Corolla much like that of *L. strigosa*, but with rather longer and narrower segments, whose upper side appears, as far as we can judge from the dried plant, to be finely downy from their base to the middle. Mr. Brown however, who saw it alive, describes this part as entirely smooth. The aspect of this pretty species is much like that of some of the smaller kinds of *Daphne*.

6. *L. ciliata*. "Leaves elliptic-lanceolate, flat, with a pellucid point; their edges finely serrated and fringed. Limb of the corolla roughish."—Gathered by Mr. Brown in Van Diemen's land. We have seen no specimens of this species, nor of any others, except the third and fifth, nor do we know of any of them being introduced into the gardens of this country.

LISSE, in *Geography*, a town of Persia, in the province of Ghilan; 60 miles N.W. of Reshd.

LISSOUEN, a town of Prussia, in Natangen; 15 miles S. of Marggrabowa.

LISSUS, in *Ancient Geography*, a town of Illyria, in Dalmatia, between the mouth of the Drin and the frontier of Macedonia. Ptolemy. Pliny calls it "Lissum Oppidum," and adds that it was a colony of Roman citizens, 100 miles from Epidaurus, where Macedonia commenced.

LIST, in the *Manufactures*, denotes the border of a stuff, or that which bounds its width on each side.

Du-Cange derives the word from *licia*, which, in the age of corrupt Latin, was used for the inclosures of fields and cities, as being anciently made with cords interlaced; or from *lisla*, *quia campum claudubant inslar lislarum panni*; as inclosing the ground after the manner that a list does a piece of cloth.

All cloths, and stuffs of silk, wool, or cotton, have lists. Lists contribute to the goodness of the stuff, and further serve to shew their quality; which has given occasion to several regulations relating to their matter, colour, work, &c.

LIST is also used to signify the inclosed field, or ground, wherein the ancient knights held their jousts and combats. It was so called as being hemmed round with pales, barriers, or flakes, as with a list.

Some of these were double, one for each cavalier; which kept them apart, so that they could not come nearer each other than a spear's length. See TOURNAMENT, and DUEL.

LIST, *Listel*, or *Listello*, in *Architecture*, called also *cincture*, *fillet*, *square*, and *reglet*, is a little square moulding, serving to crown or accompany larger mouldings; and, on occasion, to separate the flutings of columns.

LIST, in the *Sea Language*, the same with *Lust*.

LIST, *Civil*. See *CIVIL list*, and *REVENUE*.

LISTENING, according to Rohault, consists in extending or bracing the tympanum of the ear, and putting it into such a condition, as that it shall be the more affected by any tremulous motion of the external air. See EAR.

LISTENING, in the *Manège*, as when we say a horse goes a listening pace. See *ECOUTE*.

LISTENING *Trumpet*. See *TRUMPET*.

LISTER, MARTIN, in *Biography*, a physician and naturalist, was born about 1638. He was of a Yorkshire family, (settled in Buckinghamshire,) which produced a considerable number of medical practitioners of reputation; among whom was sir Matthew Lister, physician to Charles I., and president of the College of Physicians. Martin was educated under the direction of his uncle, sir Matthew, and sent to St. John's college, Cambridge, where he took his first degree in arts in 1658. In 1665 he was made fellow of his college by royal mandate. Having made choice of the profession of medicine, he pursued his studies with zeal, and travelled to the continent for the purpose of farther improvement. On his return in 1670, he settled at York, where he practised his profession for many years with considerable reputation. At the same time he applied all the leisure, which his avocations allowed him, to the investigation of the natural history and antiquities of the north of England; and having communicated several papers on these

subjects to the Royal Society, he was elected a fellow of that body. He contributed many coins, altars, and other antiquities, together with a great number of valuable natural curiosities, to the Ashmolean museum at Oxford. His various productions having made him well known to the learned in the kingdom, upon the solicitation of his friends he removed to London in the year 1684. He was at that time created doctor of physic by diploma at Oxford, upon the particular recommendation of the chancellor; and was soon afterwards elected a fellow of the College of Physicians. In 1698 he accompanied the earl of Portland in his embassy from king William to the court of France; when, having obtained introductions to the most eminent men of science at Paris, he viewed all the curiosities of that capital. On his return he published an account of this journey, which contained some things of a trifling nature, and gave occasion to a burlesque imitation, entitled "A Journey to London," by Dr. William King. At that time, indeed, when the study of natural history was little attended to, a man who had written on snails and spiders, and bestowed his attention on the minutest parts of natural knowledge, was particularly liable to incur the ridicule of wits. In consequence of the illness of Dr. Hannes, in 1709, Dr. Lister was made second physician in ordinary to queen Anne; an appointment which he did not hold long; for he died in February 1711-12.

The medical writings of this physician are not void of valuable observations, deduced from his own experience; but they are marked by a propensity to hypothesis, and too strong an attachment to ancient doctrines. There are two works on English medicinal waters, entitled "De Fontibus Medicatis Angliæ, Exercitatio nova et prior," 1682, "altera," 1684: "Exercitationes sex Medicinales, de quibusdam morbis chronicis," 1694, which was republished, with additions, in 1697. The diseases here treated of are dropsy, for which he recommends the use of drastic purgatives; diabetes, hydrophobia, syphilis, for which he admits that mercury is a specific, but avers that the mercury itself requires an antidote, which is found in the guaiacum; scurvy, gout, stone, and small-pox, for which last he extols the remedial effects of the alexipharmic medicines, and condemns the cooling practice introduced by the sagacious Sydenham. In general, indeed, he is a keen controversialist, and indulges in severe remarks upon some of his contemporaries, especially Sydenham. In his "Dissertatio de Humoribus," 1709, which is full of hypotheses, he is not less severe in his treatment of Drake and Rayfish.

The reputation of Lister is principally founded on his researches in natural history and comparative anatomy. He published nearly forty papers in the Philosophical Transactions, Nos. 25 to 585 inclusive, in addition to the following works. "Historiæ Animalium Angliæ Tractatus tres: unus de Araneis: alter de Cochleis, tum terrestribus, tum fluviatilibus: tertius de Cochleis marinis," 1678, 4to. "Exercitatio Anatomica de Cochleis maxime terrestribus et Limacibus," 1694, 8vo. "Exercitatio Anatomica altera de Buccinis fluviatilibus et marinis," 1695, 8vo. "Exercitatio Anatomica tertia de Conchyliorum bivalvium," 1696, 4to. In all these works Dr. Lister has displayed great accuracy of observation, and indefatigable industry, in detecting the most minute and curious particulars of the economy of these creatures. He also edited a correct and better arranged copy of Goedart's Treatise on Insects, in 1685; and an edition of Sanctorius's "Medicina Statica," with a commentary, in 1701. His "Journey to Paris," notwithstanding the efforts of ridicule, was well received, and contains a variety of curious matter. Gen. Biog. Hutchinson, Biog. Med. Eloy Dict. Hist.

LISTERLAND, in *Geography*, a cape on the S. coast of Norway; 20 miles N.W. of Lindesnes.

LISTING, or INLISTING, in *Military Language*, denotes the retaining and enrolling soldiers, as volunteers, for the national service. When any person is enlisted as a soldier, he shall within four days, but not sooner than twenty-four hours, be taken before the next justice of peace, or chief magistrate of a town corporate, not being an officer in the army; and before him shall be at liberty to declare his dissent to such enlisting; and on such declaration, and returning the enlisting money, and paying 20s for the charges expended on him, he shall be forthwith discharged, in presence of such magistrate. But if he shall refuse or neglect in twenty-four hours to return and pay such money, he shall be deemed to be enlisted, as if he had given his assent before the magistrate. If he declare that he voluntarily enlisted himself, the magistrate shall certify under his hand, that such person is duly enlisted, setting forth the place of his birth, age, and calling, if known; and that the third and fourth articles of the second section, and the first article of the sixth section of the articles of war against mutiny and desertion were read to him, and that he has taken the oaths mentioned in the said articles of war; viz. the oath of fidelity and the oaths in the schedule marked A and B; except in the case of recruits enlisted either in his majesty's service or in the East India company's forces under 39 Geo. III. c. 109, in which case each recruit shall, instead of the said oath of fidelity, and that contained in the schedule A or B, take the oath of allegiance directed by the 39th of the king, and contained in schedule E, and the justice or magistrate shall certify such enlistment and swearing according to the schedule F; and if any person so certified as duly enlisted shall refuse to take the said oath of fidelity before such magistrate, &c. the officer, from whom he hath received such money, may detain and confine him till he shall take it; and every military officer that shall herein offend, shall be cashiered and displaced from their office, and disabled from holding any military post, and forfeit 50l. See FOREIGN SERVICE.

LISTOWHILL, or LISTOWELL, in *Geography*, a port-town of Ireland, in the county of Kerry, situated on the river Feale. The castle, on the summit of a steep precipice above the river, was the last strong hold which held out against queen Elizabeth in 1600. It is 131 miles S.W. by W. from Dublin, and 13 N.E. from Tralee.

LISTVENNISCHNA, a town of Russia, in the government of Irkutsk, on the Argun, on the confines of China. N. lat. 51 44'. E. long. 121 20'.

LIT, a town of Sweden, in Jamtland; 10 miles N. of Östersund.

LITA, in *Botany*, so named by Schreber, from *lita*, simple, naked, or destitute, because the plant consists chiefly of flowers, with a very trifling stem, and no leaves, but a few small scales. Schreb. 795. Willd. Sp. Pl. v. 1. 1071. Mart. Mill. Dict. v. 3. (Voyria; Aubl. Guian. v. 1. 268. Vohiria; Juss. 141. Lamarek Illustr. t. 109.—Clas and order, *Pentandria Monogynia*. Nat. Ord. *Rutaceæ*, Linn. *Gentianeæ*, Juss.

Gen. Ch. Cal. Perianth of one leaf, inferior, tubular, erect, coloured, five-cleft, acute, permanent. Cor. of one petal, valvular shaped; tube cylindrical, very long, dilated at the top and bottom; limb in five equal, ovate, spreading, deep segments Stam. Filaments scarcely any; anthers five, roundish, two-lobed, nearly sessile, in the throat of the tube. Pist. Germen superior, ovate-oblong; style thread-shaped, the length of the tube; stigma capitate, abrupt. Pericarp. Capsule oblong, of one cell and two valves. Seeds very numerous.

numerous, minute, chaffy, attached to the inflexed margins of the valves.

Eff. Ch. Corolla falver-shaped. Anthers sessile, within the tube. Stigma abrupt, undivided. Capsule of one cell and two valves.

1. *L. rosea*. Willd. n. t. (*Voyria rosea*; Aubl. Guian. v. 1. 209. t. 83. f. 1.)—Flowers in pairs. Segments of the corolla acute. Root tuberous.—Gathered by Aublet in the forests of Guiana, where the natives call it *Voyria*, and eat the roasted root, which is tuberous, resembling a potatoe in shape and flavour, and throws out various spreading fibres. The stem is solitary, several inches long, chiefly concealed under the ground, square, knotty, smooth, bearing several, opposite or ternate, little, acute, fleshy scales, instead of leaves, in the manner of a *Lathraea*, and dividing at the top, where it rises above the surface, into several branches about an inch long, with more frequent knots, and rather larger scales. Each branch bears two large and handsome, rose-coloured flowers, whose tube is near two inches long, swelling at the top as well as at the base, but contracted again at the orifice. The limb is about half an inch in diameter, spreading like a star, with sharp points. Calyx short, bell-shaped. Sometimes the flowers are solitary.

2. *L. cærulea*. Willd. n. 2. (*Voyria cærulea*; Aubl. Guian. v. 1. 211. t. 83. f. 2.)—Flowers in pairs. Segments of the corolla rounded, obtuse. Root tuberous.—Native of palm forests in Guiana, where it blossoms in May. This differs from the preceding in having blue flowers, whose limb is larger, with round or obovate blunt segments, and a more dilated orifice; as well as a more deeply cut calyx. Aublet says the flowers are occasionally six-cleft, with six stamens.

3. *L. lutea*. (*Gentiana aphylla*; Jacq. Amer. 87. t. 60. f. 3. Helleborine aphyllus, flore luteo; Plum. Cat. 9?)—Stems simple, single-flowered. Segments of the corolla acute. Root fibrous, fasciculated. Gathered by Jacquin, flowering in May as well as December, in the extensive damp mountainous forests of Martinico. It is a small and tender plant, evidently akin, as Aublet remarks, to his two species above described; though the root consists only of thick entangled fibres. Stems four inches high, of a shining straw-colour, jointed, single-flowered, bearing several pairs of minute, opposite, acute scales. Flowers an inch long, slender, yellowish, inodorous, with a small, acute, stellated border. Their stigma is described as simple, capitate, and obtuse, as it ought by analogy to be, though in the figure represented cloven.

LITADA, in *Geography*, a town of the island of Negroponte, in the Grecian Archipelago; 48 miles N.W. of Negroponte.

LITANY, an old church term, applied to the processions, prayers, and supplications used for appealing the wrath of God, averting his judgments, or procuring his mercies.

The word comes from the Greek *λιτανεια*, *supplication*; of *λιτανευω*, *I beseech*. Pezron would go farther, and derive the *λιτομαι*, or *λισσομαι*, of the Greeks, from the Celtic *lit*, *feast*, *solemnity*.

Ecclesiastical authors, and the Roman order, by the word litany usually mean the people who compose the procession, and assist at it; and Du-Cange observes, that the word anciently signified *procession*.

Simon of Thessalonica mentions, that, in the ancient litanies, the people went out of the church, to denote the fall of Adam; and returned into it again, to shew the return of a pious soul to God by repentance.

LITANY, in a modern sense, denotes a form of prayer, sung or said in churches; consisting of several periods, or articles; at the end of each of which is an invocation in the same terms.

Before the last review of the common prayer, the litany was a distinct service by itself, and used some time after the morning prayer was over. At present it is made one office with the morning service, being ordered to be read after the third collect for grace, instead of the intercessional prayers in the daily service.

It has been observed, that none but those who are avowed Trinitarians can conscientiously join in this part of the church service; it has been also observed, that in the petition to be delivered from "all deadly sin," there seems to be an intimation of the popish doctrine of venial and mortal or deadly sin, and that the petition in the mass-book, from which a great part of the litany is taken, for deliverance from "sudden death," is more guardedly expressed, "*à subitâ et improvisâ morte*," i. e. from death sudden and unprovided for.

LITAO, in *Geography*, a town on the N.W. coast of the island of Timor. S. lat. 9° 2'. E. long. 124° 42'.

LITCHFIELD. See LICHFIELD.

LITCHFIELD, a township of America, in Lincoln county, Maine, 45 miles from Hallowell; containing 1044 inhabitants.—Also, a township in Hillsborough county, New Hampshire, situated on the E. side of Merrimack river, about 54 miles W. of Portsmouth; settled in 1749 and containing, in 1800, 372 inhabitants.—Also, a populous and hilly county of Connecticut, bounded N. by Massachusetts, S. by New Haven and Fairfield counties, E. by Hartford, and W. by New York. It is divided into 20 townships, containing 41,214 inhabitants. Although the face of the country is generally mountainous, the soil is fertile, yielding large crops of wheat and Indian corn, and affording fine pasture. The inhabitants are almost universally farmers, and wholly detached from maritime commerce.—Also, the chief and post-town of the above county, seated on an elevated plain, exposed to the cold winds of winter, but enjoying a large portion of the refreshing breezes of summer. Its situation is handsome, and it contains about 60 or 70 compact dwelling-houses, a court-house, a meeting-house, and 4285 inhabitants; 32 miles W. of Hartford. N. lat. 41° 46'. W. long. 73° 37'. On several small streams, some of which fall into Great Pond, a beautiful sheet of water, are three iron-works, an oil-mill, and a number of saw and grist-mills.—Also, a township in Herkemer county, New York, taken from German Flats, incorporated in 1796, and containing 1976 inhabitants. Morfe.

LIT-CHI, or LICHI, in *Botany*, Sonnerat Voy. v. 2. 230. t. 129, a valuable Chinese fruit, which, after being dried in an oven, becomes an object of commerce. It is globose, the size of a small walnut, consisting of a thick tuberculated coat, enclosing a large hard seed, enveloped in a quantity of pleasantly acid pulp. See *ΕΥΡΗΘΙΑ*, *SCYTALIA*, and *DIMOCARPUS*.

LI-TCHUEN, in *Geography*, a town of Corea; 15 miles N.W. of Long-kouang.

LITE, the name of a plaster much commended by the ancients: it consisted of verdigris, wax, and resin. Whatever virtues this plaster possessed, might be probably found in the melilot plaster of the shops in general, till the late reformation made by the London Pharmacopœia, the colour being generally given by our wholesale dealers with verdigris, not with the juice of the herb from which it took its name.

LITERÆ COMMUNICATORIÆ, in *Church History*, letters granted by the bishops to penitents, when the time of their penance was finished, by which they were again received into the communion of the faithful.

LITERAL ALGEBRA. See **ALGEBRA**.

LITERAL Character. See **CHARACTER**.

LITERALIS Calculus. See **CALCULUS**.

LITERARY PROPERTY, is that property which an author, or his assignee, may be supposed to have in his own literary compositions; so that no other person without his leave may publish or make profit of the copies. The Roman law adjudged, that if one man wrote any thing on the paper or parchment of another, the writing should belong to the owner of the blank materials (Just. 2. 1. 33.); meaning thereby the mechanical operation of writing, for which it directed, the scribe to receive a satisfaction; for, in works of genius and invention, as in painting on another man's canvas, the same law gave the canvas to the painter. As to any other property in the works of the understanding, the law is silent; though the sale of literary copies, for the purposes of recital or multiplication, is certainly as ancient as the times of Terence (Prolog. in Eunuch. 20.), Martial (Epigr. i. 67. iv. 72. xiii. 3. xiv. 194.), and Statius (Juv. vii. 85.) Neither with us in England hath there been, till some few years ago, any final determination upon the right of authors at the common law. In case of a bargain for a single impression, or a sale or gift of the copy-right, the reversion is plainly continued in the original proprietor, or the whole property is transferred to another. It has been a question much agitated in our superior courts of judicature, and at length determined by the house of lords against authors and their assigns, whether the copy-right of a book belongs to the author by common law. But, exclusive of such copy-right as may subsist by the rules of the common law, the statute 8 Ann. cap. 19, amended by statute 15 Geo. III. c. 53, has protected, by additional penalties, the property of authors and their assigns for the term of fourteen years, and hath directed, that if, at the end of that term the author himself be living, the right shall then return to him for another term of the same duration: and this is the sole right now vested in the proprietors of copies. By the statute 15 Geo. III. c. 53, some additional privileges in this respect are granted to the universities, and certain other learned societies. A similar privilege is extended to the inventors of prints and engravings, for the term of twenty-eight years, by 8 Geo. II. cap. 13. and 7 Geo. III. cap. 38. besides an action for damages, with double costs, by statute 17 Geo. III. c. 57. All which parliamentary protections appear to have been suggested by the exception in the statute of monopolies, 21 Jac. I. c. 3, which allows a royal patent of privilege to be granted for fourteen years to any inventor of a new manufacture, for the sole working or making of the same; by virtue whereof it is held, that a temporary property therein becomes vested in the king's patentee. 1 Vern. 62.

LITERARY Criticism. See **CRITICISM**.

LITERATI, **LETRADOS**, lettered, an epithet given to such persons, among the Chinese, as are able to read and write their language.

The literati alone are capable of being made mandarins.

The literati form the most distinguished part of the Chinese nation. Since the dynasty of Han, *i. e.* for more than 2000 years, they have constantly held the chief rank in the empire; and it is always from among them that masters are chosen for the education of youth; ministers, for the administration of public affairs; and magistrates, for judging the people: in a word, the literati are, in some

measure, the soul of the Chinese nation, since it is from them that it receives its moral exultance, and its civil and political being. The literati must therefore be very numerous in a state, where they enjoy every distinction attached to pre-eminence, and where every thing favours their increase. Since learning is the only means that conduct to honours, it is necessary that those who aspire to them should cultivate letters; and they must make it appear, that they have cultivated them with success, before they can obtain any civil employment. To guard against imposition, government has fixed for every city of the first, second, and third class the number of literati who can be legally promoted every year to the first degree of literature, which is that of "sieou-tsai," and which answers to bachelor of arts in our universities. Every "sieou-tsai" is accounted noble, and is never enrolled among the taxables. Of these there are reckoned to be in China 247,701 individuals, who are annually introduced to the first degree of literati; and the number of those admitted before may be supposed to be at least 20 times as great. According to this estimate there are always in China 494,020 literati, who have taken degrees, and who are, consequently, not included among the taxables. See **MANDARINS**.

LITERATI is also the name of a particular sect, either in religion, philosophy, or politics; consisting principally of the learned men of that country: among whom it is called *jukiao*, *i. e.* *learned*.

It had its rise in the year of Christ 1400, when the emperor, to awaken the native affection of the people for knowledge, which had been quite banished by the preceding civil wars among them, and to stir up emulation among the mandarins, chose out forty-two of the ablest among their doctors, to whom he gave a commission to compose a body of doctrine, agreeable to that of the ancients, which was then become the rule, or standard, of the learned. The delegates applied themselves to the business with very great attention; but some fancied them rather to have wrested the doctrine of the ancients, to make it consist with their's, than to have built up their's on the model of the ancients.

They speak of the Deity, as if it were no more than mere nature, or the natural power or virtue, that produces, disposes, and preserves the several parts of the universe. It is, say they, a pure, perfect principle, without beginning or end; it is the source of all things, the essence of every being, and that which determines it to be what it is. They make God the soul of the world: they say he is diffused throughout all matter, and produces all the changes that happen there. In short, it is not easy to determine, whether they resolve God into nature, or lift up nature into God; for they ascribe to it many of those things which we attribute to God.

This doctrine, in lieu of the idolatry that prevailed before, introduced a refined kind of atheism. The work, being composed by so many persons of learning and parts, and approved by the emperor himself, was received with infinite applause by all the people. Many were pleased with it, because it seemed to subvert all religion; others approved it, because the little religion that is left them, could not give them much trouble. And thus was formed the sect of the Literati; which consists of the maintainers and adherents to this doctrine.

The court, the mandarins, and the persons of fortune and quality, &c. are generally retainers to it; but a great part of the common people still hold to their worship of idols.

The literati freely tolerate the Mahometans, because they adore, with them, the king of heaven, and author of nature;

nature; but they bear a perfect aversion to all sorts of idolaters among them: and it was once resolved to extirpate them. But the disorder this would have occasioned in the empire prevented it: they now content themselves with condemning them in general, as heretics; which they do solemnly every year at Pekin.

LITERNUM, or LINTERNUM, in *Ancient Geography*, a town of Italy, in Campania, at the mouth of the Csanis, and near the lake called by Statius "Linternus Palus." It was a Roman colony, improved and enlarged by Augustus. The ruins of it, consisting of some heaps of stones, may be traced on the edge of a large pond in a dreary flat shore, between the mouth of the Volturnus and the promontory of Misenum. Hither Scipio Africanus withdrew from the accusations of his enemies, and here he spent his days in retirement. Tradition says, that his ashes were deposited in this place.

LITHAGOGI, of *λίθος*, *stone*, and *αγω*, *I bring away*, an epithet given by some medical writers to such medicines as work by urine, and are supposed to have the virtue of expelling the stone.

LITHAGROSTIS, in *Botany*, from *λίθος*, *a stone*, and *αγρας*, *grass*, a name faulty in itself, as composed of that of another established genus, and quite unnecessary. Gartner contrived it for the *Coix* of Linnæus, Jussieu, and others, because the *ροίζ* of Theophrastus seems to be a sort of palm. But there is no end of such critical alterations, especially when they are not founded on any thing like certainty.

LITHANTHRAX, of *λίθος*, *stone*, and *ανθραξ*, *coal*, in *Natural History*, is used as the name of the common pit coal. See *COAL*.

LITHARGE, composed of *λίθος*, *a stone*, and *αίθυρα*, *flavor*, a metallic substance, formed of the spume of lead; or, it is a calx of lead in an imperfect state of vitrification. When silver is refined by cupellation with lead, this latter metal, which is purified, and which causes the scorification of the imperfect metals alloyed with the silver, is transformed into a matter composed of small semi-transparent shining plates, resembling mica, which is *litharge*. See *Alloys of LEAD*.

This preparation of lead is of great use in roasting the stubborn ores of gold, silver, and copper; for it melts all kinds of stones and earth into glass, sooner than the metals; and by this means the metal, which is heavier, will fall through the glass, which is a thin and light substance, and will be collected under it into a regulus, with only a few dirty scoriae adhering to it. But if it be copper that is thus separated, a small portion of it is always destroyed; and if gold or silver, a like small portion is always lodged and detained in the scoriae.

But as the litharge penetrates through all sorts of vessels, and while melting rises into a scum, that often runs over their edges, the assayers never use it alone, but always mix with it such substances as may give it a clamminess, such as flints, sands, clay, or the like: they mix two parts of litharge with one part of any of these substances, and add some nitre, or common salt, that the whole may run the more easily. They shut up the vessels, which must be made very thick and solid, with a small cover or lid, cut close, and placing this in a wind-furnace, they keep it in fusion a quarter of an hour, looking at times into the ash-hole, to see if the glass have not escaped through the vessel, and run down thither. Very often it is found sweating through the sides of the vessel, like water, and falling in drops into the ash-hole; and in this case, there is no way to preserve the remainder, but to take the vessel out of the fire.

When the whole is cool, the vessel must be broke, and at

the bottom there will be found a small quantity of a regulus of lead, revived by means of the salt; in the middle, the glass of lead, which must be kept for use; and at the top a saline crust, which is to be thrown away.

Litharge is more or less white or red, according to the metals with which the silver was alloyed. Accordingly the white is called litharge of silver, and the red has been improperly called litharge of gold.

Litharge may be easily revived into lead; accordingly, much of that which is produced by refining in great is reduced, by being melted upon burning coals. The part which is least altered by mixture with other metals is thus reduced, and thus good and saleable lead is obtained. The rest of the litharge of these refineries is sold and used for various purposes.

The potters use much of it to give a beautiful gloss to their wares; it is also employed in the composition of some glasses, for it is very fusible, and assists the fusion of other substances; and it is also used by painters, dyers, skinners, and glaziers. When mixed with wine, it gives it a bright sprightly colour, but renders it extremely unwholesome. In general, it has the same properties with the other calces of lead. The litharge commonly sold is obtained from refineries, and the quantity thus procured is more than sufficient for the demand. It is employed for the preparation of some plasters and other external remedies. See *LEAD*.

LITHARGE, *Plaster of*. See *EMPLASTRUM commune*.

LITHARGE, *Vinegar of*. See *VINEGAR of Lead*.

LITHAY, or LITAY, in *Geography*, a town of the duchy of Carniola, on the Save; 15 miles E. of Laybach. N. lat. 46 3'. E. long. 15'.

LITHIASIS, (from *λίθος*, *a stone*), in *Surgery*, the disorder in which calculous concretions are formed in the urinary organs, and more especially in the bladder, occasioning a variety of symptoms dependent upon their shape, size, and situation. For further details upon this subject, see *LITHOTOMY* and *STONE*.

LITHIC, or URIC ACID. See *URINARY Calculus*.

LITHIDIA, a name which, in Hill's History of Fossils, is given to an assemblage of stones of the siliceous class, belonging to the quartz and flint tribes.

LITHOBOLIA, *Λιθοβολία*, in *Antiquity*, a festival celebrated by the Træzenians, in memory of Lamia and Auxetia, two virgins, that coming from Crete to Træzene, in a time of tumult and sedition, became a sacrifice to the fury of the people, by whom they were stoned to death.

LITHOBOLIA, or *Lapidation*, was also a common punishment inflicted by the primitive Greeks upon such as were taken in adultery.

LITHOCOLLA, or LITHOCOLLUM, formed of the Greek *λίθος*, *stone*, and *κόλλα*, *glue*, a cement used by the lapidaries to fasten their precious stones, in order for cutting them.

It is composed of resin and brick-dust. For diamonds, they use melted lead, putting them into it before it be quite cold: for other cements, they mix marble-dust with strong glue; and, to fasten their sparks, add the white of an egg, and pitch. See *CEMENT*.

LITHODÆMON, or *Lapis Dæmonum*, a name given by some authors to jet.

LITHODENDRON, a name by which, according to Dioscorides, many of the ancients express the common red coral.

LITHOGENESIA, a term used by some authors to express the formation and original of stones.

LITHOLABON, a name given by some surgical writers

writers to an instrument used in the operation of lithotomy; it is a forceps intended for taking hold of the stone.

LITHOLOGY, the systematical arrangement of stones; which see.

LITHOMANTIA, *Λιθομαντία*, in *Antiquity*, a species of divination performed with stones. Sometimes the stone called *fidrites* was used: this they washed in spring-water in the night by candle-light; the person that consulted it, was to be purified from all manner of pollution, and to have his face covered: this done, he repeated divers prayers, and placed certain characters in an appointed order; and then the stone moved of itself, and in a soft, gentle murmur (or as some say) in a voice like that of a child, returned an answer. By a stone of this nature, Helena is reported to have foretold the destruction of Troy.

LITHOMARGE, *Steinmarg*, Wern. *Argile lithomarge*, Hall. *Steinmarg*, or *Stalmar*, Swed.

This substance, which is related to the finectic kinds of clay and to steatite, occurs friable and compact.

1. *Friable lithomarge*, *Zerreibliches Steinmarg*, Wern.

Its colour is snow-white, oftener yellowish, and sometimes reddish-white.

It is found massive, disseminated, and in crusts, consisting of fine, dull, sometimes feebly glimmering scaly particles, which are either coherent or loose.

It is light, rather greasy to the touch, but adheres to the tongue. Streak shining.

It occurs in Saxony, on the Hartz, &c. generally in small masses, particularly in metalliciferous veins.

A variety from the Hartz, where it occurs in grey wacke, shews phosphorescence by friction.

2. *Compact or indurated lithomarge*, *Fest Steinmarg*, Wern.

Its colours, besides those of the friable lithomarge, are pearl-grey, lavender and purplish-blue, yellowish-grey, several shades of ochre yellow, and also flesh-red; several of these colours frequently occurring together as clouded, veined, striped, and spotted delineations.

It is found massive.

Internally it is dull. Streak shining.

Fracture large and flat conchoidal, passing into even and fine earthy; fragments indeterminate angular, blunt-edged.

It is very soft and mild, and easily frangible; greasy to the touch, but strongly adhering to the tongue. It is light.

The variegated bluish and purplish earth, vulgarly called *Wundererde* in German, or *Terra miraculosa Saxonia*, is one of the best known and finest variety of lithomarge. It is found at Planitz, near Zwickau, in Saxony, in beds of coal. A fine flesh-red variety occurs at Rochlitz in Saxony, in disintegrated porphyry. Lithomarge is also met with in several other parts of Saxony, and on the Hartz, in Bohemia, Moravia, Bavaria, and Siberia.

Compact lithomarge is partly found in veins, such as tin stone veins, partly, as that of Planitz, on beds of coal; also (the yellow variety) in the crystalline geodes of the Topaz rock, in basalt and amygdaloid. At Zöblitz, in Saxony, it occurs in serpentine.

This substance, of which we are still without a good chemical analysis, appears to pass into steatite, meer-schaum, and also into variegated clay.

It has been frequently confounded by authors with porcelain earth, fullers' earth, bole, &c.

The variety of lithomarge occurring in serpentine, is used for polishing this latter stone. It was also formerly employed in medicine, particularly the variegated variety, which was dignified with the appellation of *terra miraculosa*.

VOL. XXI.

LITHONTRIPTICON TULPII, the name of a famous diuretic medicine, invented by Tulpinus, and given with great success in cases of the stone, but requiring great judgment and caution in the administering of it.

The preparation is this: take a drachm of carduus without their wings, and a drachm of lesser carduus without their husks, powder them fine, and pour upon them an ounce of rectified spirit of wine, and half an ounce of spirit of nitre; set them to infuse, without heat, for five or six days, stirring them from time to time. The phial must not be stopped close; because, if it be, the continual fermentation will burst it. The dose is from fourteen to fifteen, or twenty drops, in a glass of wine and water. It is to be taken in a morning, an hour after eating a mess or broth, and may be repeated for three or four days.

It is remarkable, that this mixture never ceases fermenting for many years; but if it be too fast corked, will break the glass; if it be slightly stopped, it only throws out the cork with an explosion. Mem. de l'Acad. Par. 1709. 1. 25^e. edit. Par.

LITHONTRIPTICS, or as it is perhaps more correctly written, LITHONTHRYPTICS, in *Medicine*, from the Greek *λίθος*, a stone, and *τρύπτω*, I break, such medicines as were supposed to possess the property of dissolving the stone in the bladder and kidneys. See STONE.

Various simple and compound drugs were believed to be capable of dissolving the calculous concretions of the urinary passages, in ancient times. These medicines, however, had been but too generally found, by modern practitioners, to be destitute of any active power of this sort, when, in the former part of the last century, a new solvent for the stone was announced by a lady, with so much evidence in favour of its efficacy, that the English parliament granted her a large pecuniary reward for divulging the secret, and medical practitioners resorted to it with eagerness, and investigated its properties with great care, and in many instances had the satisfaction to observe a temporary removal of the distressing symptoms succeed to its use. It appeared, however, ultimately, that the solvent power of Mrs. Stephens's medicine was a gratuitous supposition; for on examining, after death, the bodies of the persons in those very instances, on the success of which the reward was given, it was discovered that the stones had all the time remained in the bladders of the patients, though they were supposed to have been voided by the gradual solution of them effected by the medicines.

The principal instance of a supposed cure which was brought forward, was that of Mr. Gardner. This man was examined in December 1748, by able surgeons, and found to have a stone in his bladder; after this he took Mrs. Stephens's medicines for eight months without intermission; and at the end of that time he declared himself free from all his usual complaints; and on searching him no stone was perceived in the bladder. Mr. Gardner died about three years afterwards, and his body was opened. When the bladder was examined, there were found in it six preternatural apertures of different sizes, the largest of which was capable of admitting the end of a finger. These passages led to morbidly formed sacs in the internal coat of the bladder, which shielded the calculi from the touch of the surgeon's sounding staff. In a word, though the subject was taken up by Dr. Hartley and others, and the medicine believed by some to possess all the powers which had been ascribed to it; it was not only found, in several instances, that the calculi still remained in the bladder after death; but the distressing symptoms were found to recur, or even

to resist the influence of the medicine, in a great many others.

Mrs. Stephens's medicine consisted principally of *soap*, and *lim*, prepared from shells; *i. e.* of lime, a fixed alkali, and a little oil. From theoretical notions, the celebrated Dr Mead pronounced that a medicine containing such caustic materials as *lime*, must injure the bladder by its corrosive powers, and therefore condemned the internal administration of it. Yet he did not know whether the lime could actually reach the bladder through the medium of the circulation with its caustic powers unchanged; a circumstance which the investigations of modern chemistry render improbable. And as for the substitute, soap-lees, which had been proposed for the lime, he thought it scarcely less safe than the former. Dr. Whytt, of Edinburgh, after considering the inconveniences of this celebrated specific, resolved to omit the soap, and to try what virtues lime-water might have in dissolving calculi; and he made many experiments on the qualities of the varieties of lime-water, made with the lime from lime-stone, and that from oyster shells, upon fragments of urinary calculi immersed in it. He concluded by recommending the copious potation of lime-water from shells, and adduced several instances of the beneficial effects of this remedy.

Now the truth appears to be, according to the result of more accurate observation, that all the alkaline and absorbent medicines, potash, soda, lime, magnesia, &c. and especially the alkalis, are capable of affording very material relief to the distressing feelings, connected with the presence of calculi in the urinary passages; that they operate as preventives of a farther increase of the bulk and quantity of these concretions; but that they do not reach the urinary organs (after having passed the organs of the digestion, been taken up by the lacteals, and mixed and circulated with the blood) unchanged in their chemical qualities, or in a sufficient quantity to produce any diminution of the calculi already existing there.

They seem to possess this preventive power, however, by their operation in the first passages. It is now known, that the ordinary calculus of the bladder and kidneys consists of a peculiar animal *acid*, which has been called the *uric* or *lithic acid*, from its abundant existence in the urine and its calculi. Now, although this acid is not formed in the chyle, or any of the fluids in the first passages; yet its rudiments appear to exist there; and experience has determined, that whatever diminishes the formation of acidity in the organs of digestion, diminishes also the quantity of the *uric acid* which shews itself in the urine, and *vice versa*. But it is the peculiar property of the alkalis and absorbent earths, to neutralize acidity of every description; and the alkalis are possessed of this property in a greater degree than the earths. Whence we may readily perceive how the use of these medicines, by neutralizing the acids, which are produced by a morbid or imperfect digestion of the food, and preventing the formation of that matter, which concretes in the urine into calculi, should give material relief to the patient. It is not, however, very easy to understand how the prevention of this formation should give so much relief, while the original concretion remains in the bladder, undiminished in weight and size. Whether its surface becomes more uniformly smooth and less irritating, therefore, to the internal coat of the bladder, under the use of these medicines, it would be very difficult to ascertain, since we have no opportunity of comparing its present condition.

It is further to be observed, however, that there is one variety of calculus found in the urinary passages, for which the alkalis and absorbents are incapable of affording any

relief; as, from its chemical composition, it is altogether insoluble in these substances, even when directly immersed in them. It is a triple salt formed by combination with the phosphoric acid, and is, therefore, only to be dissolved or decomposed by an agent of a directly opposite quality to that of the alkalis; namely, by a mineral acid, which unites with the earthy and alkaline base. See NEURALGIA and STONE.

Dr. Hartley has published, in the London Gazette, the following receipt for making a lithontriptic electuary. Take five pounds of Alicant soap, shaved, and one pound of oyster-shell-lime: put them into a tin vessel, and pour upon them five quarts of water; make the water boil, till the soap be perfectly dissolved in it, and then strain all into a glazed earthen vessel. Expose the mass to the air, stirring it every day till it becomes both mild to the taste, and of a proper consistence to be formed into pills, or long pellets, without sticking to the fingers. This may be expected to happen in two or three months. If it becomes sufficiently mild before it has acquired a due consistence, it may be brought to this, by being heated over the fire, in a tin vessel: if it acquires a too hard consistence, before it is sufficiently mild, it must be softened with water. This is what the doctor calls the lithontriptic mass or electuary; which he orders to be made in a tin vessel, because a brass or copper one would make it emetic.

He gives another more expeditious way of making it, which is this: pour two gallons of water upon a pound of oyster-shell-lime; stir it two or three times, and when it has fallen to the bottom, pour off the clear part of the water. Repeat this fifteen or twenty times, or till the clear water, which is poured off, be almost tasteless; leaving about five pints of water upon the lime, after the last ablution. Then pour this mixture of water and dulcified lime upon five pounds of Alicant soap, shaved; and proceed as directed in the first receipt. The mass, prepared in this manner, will be fit for use in a few days, or even immediately; but then the doctor prefers the foregoing receipt, where time can be allowed for it.

If the mass of soap, and oyster-shell-lime, dulcified in either of the above-mentioned ways, be made of the consistence of an electuary, it is then called the lithontriptic electuary; which for cure is more convenient than the mass, for those who desire to take the medicine dissolved in a liquid vehicle, as milk, water sweetened with honey or sugar, water flavoured with brandy or rum, and small beer.

Where a person is supposed to have a large stone in the kidneys or bladder, he ought to take every day as much of the mass or electuary as contains two ounces of the soap, unless his pain and provocation to make water be violent; in which case it will be proper to begin with about half this quantity, and to increase it as he can bear. The medicine ought also in this case to be dulcified in an extraordinary degree.

By this medicine, the doctor thinks the generation of gravel, and gravel-stones, may be entirely prevented. See STONE.

It is likewise recommended in disorders of the stomach and bowels, arising from, or attended with, acidities there; and in gouty habits. The patient may, in many of these cases, begin with such a quantity every day as contains an ounce of soap, and afterwards increase or lessen this quantity, as he finds occasion.

LITHOPHAGI, of *lithos*, *stone*, and *phago*, *to eat*, a name given to those who are capable of eating and digesting stones; instances of which are given by Boyle, Exp. Phil. p. 11. eT.

eff. iii. p. 86. Bulwer, Artificial Changeling, p. 327. and Paulhan, D. S. Physique, art. *Diglossin*.

LITHOPHAGUS, or **STONE-EATER**, in *Natural History*. Under this name DeBois describes a small worm, which destroys and feeds upon bones. It is covered by a small, very tender, and brittle shell, of ash-gray and greenish colour. This shell is pierced at both extremities; the worm evacuates its excrements through one of the apertures, while the other functions for an outlet to the head and legs. The animal itself is blackish; its body is composed of rings with six feet, three at each side; each foot with two joints. Traces of this worm are, according to the same author, sometimes seen in the layers of testis. Its progressive motion is effected by its head, with which it works its way, while the remainder of its body rolls on its feet. It has four jaws, which serve the purposes of teeth; and from its mouth issues a thread, of which it combs out its shell. It is furnished with ten small black eyes, five on each side, and disposed in a curved line like a crescent. This worm undergoes a metamorphosis in its shell, but it is not yet known what new form it adopts. DeBois adds, that more than forty worms have been seen to issue from out the chrysalis: their heads were black, the feet very distinct, and the body partly of a yellow and partly of a red colour. Latreille conjectures this to be the larva of an insect belonging to the tinca tribe.

LITHOPHILA, in *Botany*, so called by Dr. Swartz, being derived from *lithos*, a stone, and *philos*, or *stems*, for it is an inhabitant of barren, stony places. Swartz Prod. 14. Ind. Occ. v. 1. 47. Schreb. 782. Willd. Sp. Pl. v. 1. 154. Mart. Mill. Dict. v. 3. Class and order, *Diandria Monogynia*. Nat. Oed. *Caryophyllis*, Linn. *Caryophyllis affinis*, Juss.

Gen. Ch. Cal. Perianth inferior, of three lanceolate, acute leaves. Cor. Petals three, ovate lanceolate, erect, meeting together, the length of the calyx-leaves. Nectary of two opposite leaves, smaller than the corolla, carinated, acute, erect, compressed. Stam. Filaments two, awl-shaped, erect, from the base of the germin, as long as the nectary; anthers roundish. Pyl. Germen superior, roundish; style erect, equal in length to the filaments; stigma obtuse, emarginate. Peris. two-celled? Seeds unknown.

Eff. Ch. Calyx of three leaves. Corolla of three petals. Nectary of two leaves.

1. *L. micoides*. Swartz Ind. Occ. v. 1. 48. t. 1.—A native of rocks in the desert island of Navara, in the Western ocean.—Root very firmly attached to the rocks. Stems numerous, branched, very short, thickish. Branches set with withered, whitish scales. Leaves small, stem-filike, narrower and embracing the stem at their base, linear, obtuse, channelled, spreading. Flowers crowded together, whitish, on axillary and terminal stalks; each flower the size of a small pin's head. The whole plant is extremely minute, scarcely half an inch high, and the parts of fructification are so small as to require a magnifying glass for examination. This is the only species known.

LITHOPHOSPHORUS, the *stone phosphates* described under the name, in the works of ancient mineralogists, belong partly to a variety of sulphate of barytes (Bosnian stone), partly to some varieties of fluor spar; the name being derived from the property they possess of giving out light when scratched, or thrown on burning coals.

LITHOPHYTA, in the Linnæan system of *Natural History*, the fourth order of vermes or worms; being composite animals, sessile to, and fabricating a fixed calcareous base, each animal: this order contains 59 species under four

genera; viz. the *tubifera*, or red tubular coral, *madreporas*, or brain-stones, *milipora*, and *elipora*. See GERMANIA.

One of the most remarkable species of the first lithophyta we have any where an account of, is that described by Mr. Lowenheek, though without any particular name, in the Philosophical Transactions, 1762, p. 142.

LITHOPTERIS, in Botany, in *Journal de Botanique*, a name given by Mr. Lloyd to one of the lithophytes of the fern kind.

LITHOPERMUM, in Botany, from *lithos*, a stone, and *perma*, the *calyx*, meaning the small dark, blackish and polished part of the fruit. Linn. t. 1. 70. DeCand. v. 2. Willd. Sp. Pl. v. 1. 211. Mart. Mill. Dict. v. 3. 154. Pl. Brit. 215. Nat. Oed. v. 1. 130. Tournef. t. 25. Class and order, *Diandria Monogynia*. Nat. Oed. *Alyrifolia*, Linn. *Perispermum*, Juss.

Gen. Ch. Cal. inferior, of three or four, or five deep, awl-shaped, erect, lanceolate, acute leaves. Cor. of one petal, five-lobed, erect, as long as the calyx; tube cylindrical; limb obtuse, or erect, closed, hard, and divided into five segments; throat pervious. Stam. Filaments two, very short; anthers of long, in the mouth of the corolla. Pyl. Germens four; style central between them, three-lobed, the length of the tube; stigma oblique, divergent. Perisperm, except the calyx, become spreading, and lobed; the fruit, which it exceeds in length, in its early state, four, ovate, pointed, hard and smooth.

Obs. *L. difformis* has an inflated calyx, and but two seeds, each, as in the others, of a single cell.

Eff. Ch. Corolla funnel-shaped, its mouth pervious and naked. Calyx in five deep segments.

The genera of the order of *Alyrifolia* have been thought by some to have been distinguished with too great minuteness by Linnaeus. The character of the present chiefly differs from *Pulmonaria* in the deep divisions of its calyx; which part, nevertheless, in some species of the latter, is very nearly as much divided. Willdenow has sixteen species of *Lithospermum*, of which three are British, *officinale*, *arvensis*, and *purpureo-ceruleum*. The flowers are generally blue or whitish, rarely yellow; the habit herbaceous, rarely in some degree shrubby, very hairy or batty; most of them annual; leaves simple, undivided, entire, alternate, almost universally sessile. The following examples may suffice.

1. *L. officinale*. Common Groundsel, Gray M.F. or Gray Millat. Linn. Sp. Pl. 189. Engl. Bot. t. 112.—Corolla even. Corolla scarcely longer than the calyx. Leaves lanceolate, venous, rather acute.—Native of waste ground, where the soil is dry, gravelly, or chalky, in various parts of Europe, being perennial, and flowering in May. The whole herb is of a dull dusky green, leafy, and grows to a high; the leaves paler beneath, the roots and a good deal of their upper surface each spreading, in many places, polished tubercles. The fruit small, like bird's-foot, each leafy spike, which are first received, thence, etc. The seeds, two of which only are usually perceived, or perhaps, are remarkable for their pointed, finely wrinkled, though sometimes tinged with brown. Theorist says, however, has given occasion to a report of its being a great worm-eater, and really calcareous, but this appears to be without foundation; as well as their supposed ability to calcify complaints, which seems to have arisen from the fruit, green, three; just as spotted or blighted vegetables were presented good for the lungs.

L. arvensis. Corn Groundsel, or Bahad Alkanet. Linn. Sp. Pl. 190. Engl. Bot. t. 123. Pl. Dan. t. 2.

Seeds rugged. Corolla scarce longer than the calyx. Leaves obtuse, without lateral veins.—Native of fields and waste places, in a dry sandy soil, throughout Europe. The root is annual, its bark affording a fine red stain, like Alkanet, with which the country girls, in the north of Sweden, are accused by Linnæus of staining their cheeks. The stem is bushy, spreading, hardly a foot high. Corolla white. Seeds brown, rugose.

L. purpureo-ceruleum. Creeping Purple Gromwell. Linn. Sp. Pl. 190. Engl. Bot. t. 117. Jacq. Austr. t. 14.—Seeds even. Corolla much longer than the calyx. Leaves lanceolate, acute, without lateral veins.—Native of bushy waste ground, in the more temperate climes of Europe, especially where the soil is calcareous, flowering in May. With us it is esteemed a rare plant. The root is perennial, black and creeping. Stems herbaceous, scarcely branched, while barren procumbent and rooting, otherwise erect, round, leafy, about a foot high, terminating in a forked leafy cluster, of several handsome purple flowers, with a pale reddish tube. The seeds are often abortive. There are five blunt hairy swellings round the orifice of the tube, which, though they do not close that part, render the generic character somewhat ambiguous. Such however are found in all the British species, and in some, though not all, of the exotic ones.

L. fruticosum. Shrubby Gromwell. Linn. Sp. Pl. 190. (*Anchusa lignosior montpelienium*, flore violaceo; Barrel. Ic. t. 1168.)—Stem shrubby, erect. Leaves linear, hispid. Segments of the corolla slightly pointed; tube hairy.—This beautiful plant occurs on rocky exposed hills and cliffs in the south of France, Italy, and the Levant. Its shrubby bushy stem, and copious rosemary-like leaves, distinguish the species. The flowers are of a most vivid blue.

L. hispidulum. Bristly Woody Gromwell. Sm. Prodr. Fl. Græc. Sibth. v. 1. 114. Fl. Græc. ined. t. 162.—Stem shrubby, diffuse. Leaves elliptic-oblong, obtuse, hispid. Branches hoary.—Gathered by the late Professor Sibthorp, on rocks in the isle of Rhodes. Its flowers are nearly as beautiful as the last, but their segments are more rounded, and the throat more inflated, that part being, in both these, destitute of any marginal swellings or appendages. The present is not mentioned by Willdenow.

L. orientale. Yellow Perennial Gromwell. Linn. Syst. Veg. ed. 14. 185. Willd. n. 9. Curt. Mag. t. 515. (*Anchusa orientalis*; Linn. Sp. Pl. 191.)—Seeds rough with sharp points. Spikes long, leafy. Leaves oblong, wavy.—Native of the Levant; hardy and perennial in our gardens, flowering in May and June, and distinguished by its full-yellow corolla, whose segments are rounded, and orifice without swellings. The floral leaves are sometimes heart-shaped, sometimes ovate or lanceolate; those of the stem oblong or lanceolate, wavy at the edges; all hairy.

Several peculiarly bristly species of this genus were found and described by Forskäll, which have been adopted by Vahl and Willdenow.

LITHOSPERMUM Officinale, seu *Milium Solis*, Common Gromwell, in the *Materia Medica*, is found in various parts of England, on a dry gravelly soil, and flowers in May and June. According to Haller, this plant possesses narcotic powers; but its seeds only have been medicinally employed. These seeds have long excited the attention of naturalists, on account of their exquisitely polished surface, and stony hardness. The internal substance is softer, and seems to consist of a farinaceous, sweet, and oily matter, which becomes rancid on being long kept. The stony appearance of these seeds formerly suggested their efficacy in calculous and

gravelly disorders, to persons whose judgment was influenced by superstitious and absurd conceits. But though modern writers do not allow the lithoniptic character of the *milium solis*, yet they generally ascribe to them a diuretic quality, a power of cleansing the urinary passages, and of obviating strangury, especially when employed in the form of an emulsion; but Woodville observes, that the free use of any bland diluent would probably answer these purposes equally well. The absorbent virtue ascribed to these seeds is wholly groundless, being irreconcilable to the principles of chemistry. Woody. Med. Bot.

LITHOSTROTA, among the *Ancients*, pavements made up of small pieces of cut marble of different kinds and colour. See *TENSELATED*.

LITHOSTROTION, in *Natural History*, the name of a species of fossil coral, composed of a great number of long and slender columns, sometimes round, sometimes angular, jointed nicely to one another, and of a larry or radiated surface at their tops. These are found in considerable quantities in the northern and western parts of this kingdom, sometimes in single, sometimes in complex specimens.

LITHOTOME, from *λίθος*, a stone, and *τομή*, to cut, has been given to a variety of cutting instruments, which have been employed for making an opening into the bladder, in order to extract the stone. The most celebrated of all is the lithotome caché of Frère Côme, of whose instrument and methods of operating we shall have to speak in the following article.

LITHOTOMY, from *λίθος*, a stone, and *τομή*, to cut, signifies, in *Surgery*, the operation by which a stone is extracted from the bladder.

Surgical writers inform us, that urinary calculi admit of being extracted from three different situations, *viz.* from the kidney, the urethra, and the bladder. The question, whether a stone ought ever to be cut out of the kidney, will have due consideration given to it under the head *NEPHROTOMY*; and the removal of calculi from the urethra will be treated of in the article *URETHRA*. Our present observations will be confined to the stone in the bladder, a subject of infinite importance, whether we contemplate the severity or frequency of the affliction; its incurableness by medicines, or the perils and difficulties of the operation for its relief; the numerous modes of cutting for the stone, or the nice judgment requisite not only in the choice of a method, but also in the selection of instruments; the anatomical knowledge which the operator ought to possess; or, finally, that happy, though rare, combination of gentleness, dexterity, and resolution, so essential in constituting a distinguished and successful lithotomist. We have heard of a Pott, who would finish the operation by four or five movements, and fill every spectator with admiration of his superior skill. True skill, however, rather consists in doing a thing as safely as possible, than with the utmost quickness. Now, if it be certain that lithotomy is more likely to be followed by the patient's recovery, when no manual roughness is exercised, rapid operating must be condemned by the judicious and discerning, however calculated it may be to excite the applause and admiration of the inexperienced student. Pott, we are informed, was remarkably successful in his operations for the stone: but it must be asked, did he not lose some of his patients? If he did,—great as his success might be, we are justified in thinking that it would have been still greater, had it been his custom to aim at gentleness more than expedition. The example of Pott, therefore, is not to be imitated in this respect; and that he even acted in op-

position to his own principles is fully proved by the following passage: "I cannot omit this opportunity of adding a few words on a subject, which appears to me highly deserving of some notice, as its influence may be very extensive, and very prejudicial: it is the false idea which the by-standers at an operation generally have of chirurgic dexterity: to which word they annex no other idea than that of quickness. This has produced a most absurd custom of measuring the motion of a surgeon's hand, as jockeys do that of the feet of a horse, viz. by a stop-watch; a practice which, though it may have been encouraged by operators themselves, must have been productive of most mischievous consequences. *Vite et celerrime* are both very proper characteristics of a good chirurgic operation: but *vite* stands, as it should do, in the first place; as the patient, who suffers the smallest injury from the hurry of his operator, has no recompence from the reputation which the latter obtains from the by-standers. In most of the capital operations, unforeseen circumstances will sometimes occur, and must be attended to; and he who, without giving unnecessary pain from delay, finishes what he has to do in the most perfect manner, and the most likely to conduce to his patient's safety, is the best operator." (Pref. to Obs. on Fist. Lachrymalis.) We should not have premised these remarks, had we not often seen surgeons guilty of unwarrantable hurry and roughness in the performance of lithotomy; and did we not believe that the inflammation of the bladder and peritoneum, of which patients usually die after the operation, may, in numerous instances, be imputed to such a cause.

The stones, which are met with in the human bladder, are not all originally formed in this viscous: many descend through the ureters from the kidneys; but yet it is not to be denied, that most of them are first produced in the bladder itself, by a spontaneous concretion of particular salts contained in the urine. It may be inquired, Is the existence of a centre, round which the calculous materials are deposited and arranged, absolutely necessary to the formation of such concretions? It is well known, that whenever an extraneous substance lodges in the bladder, it becomes the nucleus of a stone: but, on the other hand, the centre of many calculi presents no particular appearance, nor any mark from which we can infer that they had any central substance, upon which they increased to their present size. Possibly, says Richerand, a clot of blood, or a piece of thickened mucus, may serve as their base, and yet, after a time, disappear. However this may be, urinary calculi offer numerous differences in respect to their size, shape, number, density, composition, and the manner of their being contained in the bladder. *Nesogr. Chir. tom. iii.*

In some cases, the bladder only contains one stone; in others, it includes several. In this last circumstance, the calculi are always smaller; their diminished size being in proportion to the greatness of their number. It has been estimated that, on the average, about three-fourths of calculous patients have only one stone in their bladder. Our own individual experience would make the proportion much higher, perhaps five or six out of every seven. Sometimes the bladder contains two calculi; but a larger number may occur from three to sixty, or more. Their size varies from that of a bean to that of a cocoon. The museums of the *École de Médecine* at Paris, and that of professor Fourcroy, exhibit specimens of calculi, which filled the whole cavity of the bladder. In the *Philosophical Transactions* for 1800, Mr. James Earle has described an enormous stone, which could not be extracted from the bladder; the attempt having been made in vain by Mr. Cline. Indeed the calculus filled almost the whole of the pelvis, and could not

be taken out of the dead subject without considerable difficulty. The weight of this immense stone was forty-four ounces; its form elliptical, with a long axis of sixteen, and a shorter one of fourteen inches. This, however, was an extraordinary case; and the average size of calculi met with in the bladder, is from the bulk of a pigeon's to that of a hen's egg.

The varieties of shape are innumerable: most of the stones, however, which are found in the bladder, are oval, and more or less flattened. Their surface is sometimes smooth and rounded; very often it is irregular and rough. Stones, fludded with asperities, are frequently termed *mulberry calculi*, and that these must produce considerable irritation of the bladder, and a vast deal of pain, is a fact which requires no comment. We saw a stone extracted a few weeks ago, the outer surface of which was quite smooth and of a light colour; but on breaking a portion of it away, the inner part of the calculus presented a granulated and dark brown appearance. The generality of stones taken from the human bladder are hard and resisting; but some are exceedingly friable, giving way to the slightest pressure, and breaking into small pieces, or even into a sort of gritty matter.

The chemical composition of urinary calculi is far from being always the same. The learned investigations of Wollaston, Pearson, Fourcroy, and Vauquelin, have discovered, that the materials may consist of uric acid, urate of ammonia, phosphate of lime, ammoniaco-magnesian phosphate, oxalate of lime, silex, and a peculiar modification of animal matter. The basis of these concretions was ascertained by Scheele to be the uric acid. Other species were afterwards detected. Dr. Wollaston, whose dissertation was published in the *Philosophical Transactions* two years before the memoir of Fourcroy and Vauquelin was read to the French National Institute, anticipated nearly every thing which the French chemists announced as their own discoveries; and it is very remarkable (as professor Murray has noticed), that although the experiments of Pearson, published in the *Philosophical Transactions* the year after Wollaston's, are referred to in that memoir, not the slightest mention is made of the discoveries of this latter gentleman! As our department is surgical, and not chemical, we shall quit this subject with briefly stating, that Dr. Wollaston has arranged urinary calculi into four species. 1st. The uric acid concretion. 2dly. The fusible calculus, or phosphate of ammonia and magnesia. 3dly. The mulberry calculus, or oxalate and phosphate of lime. 4thly. The bone earth calculus, or that composed of the phosphate of lime.

It will be with regret, that we shall presently have to state the little practical advantage hitherto derived from the knowledge of the chemical composition of urinary calculi.

These concretions are usually quite free and unconnected, so that the particular situation, which they occupy in the cavity of the bladder, is subject to change, being determined entirely by their own weight, or the contractions of the organ containing them. In some instances, however, they are adherent to the parietes of the bladder, and continue fixed in one place. Such adhesion may happen in three manners. 1. The stone may have been formed in a cul-de-sac appendage, consisting of a protrusion of the lining of the bladder between the fibres of its muscular coat; or, after being originally lodged in the common cavity of the bladder, it may have been forced into a pouch of this kind by subsequent contractions of this viscous. 2. The stone may be lodged in that portion of the ureter which runs obliquely between the coats of the bladder. 3. Lastly,

the irregular surface of a calculus may be, as it were, implanted in the fungous granulations, which occasionally arise from the inside of the bladder, and, in this circumstance, the stone can only be extracted by tearing its connection.

The calculi, which lie in a sort of cul-de-sac protrusion of the lining of the bladder, are often named *encysted*. We believe that a stone, thus encircled, is not likely to cause any real pain; the containing pouch becomes habituated to its presence; and the sensible inside of the bladder is not exposed to any irritation or injury from it. We conceive it possible for some of the alleged dislocations of stones to have taken place, in which the extraneous body became thus pressed, between the fasciculi of muscular fibres, into a cul-de-sac of the inner membrane of the bladder. A stone encysted in this manner would, in all probability, neither require extraction, nor admit of it.

Blind and brutal operators are generally eager to try hold of any excuse for their misconduct, or ill success. The adhesion of the stone has been frequently employed as a defence against the attempt, when the attempts to extract the foreign body have failed. Encysted calculi, generally, cannot be touched with a sound, and both on this account, and because the symptoms are far more lenient than those of a stone in the bladder, such cases do not demand the performance of lithotomy. A stone in the lower part of the ureter could not be touched with the sound, and would be attended with effects different from those of a calculus in the cavity of the bladder. Now, these are the only examples where the extraction of the stone would be impracticable on the ground of adhesion, and they are certainly instances in which an intelligent surgeon would never begin the attempt. But we assert with confidence, that when a calculus is truly lodged in the cavity of the bladder, no adhesion can be a just excuse, or reason, for its not being extracted. We must be convinced, with that eminent surgeon Le Dran, that an animated body, which subsists by a circulation of fluids, and another body, which owes its bulk entirely to an apposition of matter, can never become one and the same by any kind of adhesion, let it be ever so strong. Le Dran made no doubt, that there were such things as adherent stones, because he had seen instances of them. But these adhesions ought not to have hindered the stone from being extracted, provided it could be laid hold of with the forceps. In 1733, this surgeon cut a lady, who extracted a stone, that weighed seven ounces and a half. The side of it was uneven, and in a manner entirely covered upon that part of the bladder which is connected with the rectum. This incrustation was occasioned by the inequalities of the stone, which had produced an excoriation of that part of the bladder upon which they pressed, and in consequence thereof, a number of fleshy or fungous excrescences arose from the excoriated surface, and had lodged themselves in the cavities of the stone. The adhesion was broken with terrible pain. Le Dran, at subsequent periods, extracted from three patients stones, which adhered in the same manner. In 1715, he was performing an operation, performed by M. Moreau, when a stone was extracted, which was shaped like a crab-shell, or gill, and brought out with it a fungus, that circled the stone at its narrowest part. As this fungous excrescence joined round, and covered the middle of the stone, no new incision could be formed in that part, but were made at the two extremities, which was the reason of its being so shaped. It had, however, fixed it so completely in the bladder, that it could not possibly change its situation. *Traité des Opérations de Chirurgie.*

Of all animals, man is said to be the most subject to urinary calculi. The human urine contains a particular acid, so little soluble, and so disposed to produce concretions, that, frequent as the disorder is, it is rather a matter of surprise, that it is not even more common. In warm countries, like Spain and Africa, as well as in nations much to the north, such as Sweden, the disease is exceedingly rare. In temperate climates, it prevails the most in cold damp countries, like England and Holland; and, according to Richerand, it occurs in some of the provinces of France much more than in others, patients with the stone being more numerous in the northern, than the southern departments of that empire.

Children and old people are more frequently afflicted than adults, and women are less exposed to the disorder than men.

Symptoms of a stone in the bladder.—A stone in the bladder occasions pain, and derangement of the excretion of the urine; and when a suspicion of the disease is excited by these ambiguous symptoms, it can only be confirmed by introducing an instrument, called a sound, into the bladder. The pain produced by the presence of a calculus in the bladder, has the particularity of always affecting, in a very remarkable manner, the extremity of the penis. The glans becomes the seat of an itching sensation, which daily increases in violence; and patients, especially children, often get into the habit of pulling forwards the prepuce, in order to obtain relief. Hence, this part is frequently elongated in an extraordinary degree. This sympathetic sort of pain is more acute the larger the stone is, and the greater the irregularity of its surface. When the bladder is full of urine, the pain is not insupportable; but just at the period when the discharge of that fluid is finished, the suffering becomes intolerable, because, at this instant, the bladder contracts, and embraces the foreign body with considerable force. All rough exercises augment the pain; but walking over an uneven country, riding on horseback, and the jolting of a carriage particularly, have such an effect. When the patient is subjected to these exercises, he not unfrequently discharges a few drops of blood from the urethra.

The desire to make water comes on very often, and the urine, as it flows, is attended with a sensation of heat, which changes into a burning kind of pain at the extremity of the penis. The stream of water is sometimes interrupted all on a sudden. The patient vainly endeavours to continue the evacuation; he applies his hand to the perineum; he moves about, lies down, or, in some way or another, alters his posture, and the urine then begins to run again. The movableness of the stone makes it every now and then fall against the orifice of the neck of the bladder, and thus prevent, for a time, the exit of the urine.

The incessant irritation, produced by the presence of the calculus, extends to the rectum; the patient is continually teased with an inclination to go to stool, and the efforts, which his imaginary want causes him to make, bring on, in many instances, hemorrhoidal complaints, or even a prolapsus ani.

In the course of time, the pain becomes more acute and unremitting. The stone increases in size, and, by continually pressing upon the inferior part of the bladder, makes the patient experience a most painful sense of weight about the rectum. The evacuation of the urine is attended with more and more difficulty. The parietes of the bladder inflame, and are rendered thicker; its inner surface ulcerates; the urine becomes blended with matter and blood; a slow sort of fever occurs; and the patient, after lingering a great while in misery and pain, falls a victim to the disorder.

disorder. On opening the body after death, the bladder is found contracted, and its coats thickened, indurated, and more injected with blood, than in the healthy state.

The fatal termination, to which these cases tend, when unrelieved, is subject to considerable variety. Some patients have been known to live with a stone in their bladder ten, twenty, and even thirty years, without the pain being so severe as to incline them to submit to lithotomy. Richerand moreover assures us, that calculi, of very large size, and irregular surfaces, have sometimes given rise to no symptoms, by which their presence could be suspected. This author tells us, that, as he was once practising operations on the dead subject in the Hôpital de la Charité, he extracted an enormous mulberry calculus from the bladder of a patient who had died of some other disease, and who, while living, had betrayed no complaints, indicating that he was afflicted with the stone. This calculus, which was composed of the oxalate of lime, was exceedingly heavy, and by its weight, darkness of colour, and the manner in which its surface was studded with obtuse points, bore a great resemblance to a scoria of iron. It is preserved in Fourcroy's museum, where it was deposited by Boyer.

The symptoms of a stone in the bladder are so fallacious and equivocal, that every prudent surgeon avoids delivering a positive opinion, before he has sounded the patient. Certain complaints may make him suspect the nature of the case; but he must never presume to be certain, until he has actually touched and felt the stone, by means of a metallic instrument, passed through the urethra into the bladder. The general symptoms of a stone in the bladder are not peculiar to this disorder; they belong to several other affections, for which the practitioner may be consulted. An enlarged prostate gland produces many effects, like those of a stone in the bladder. There is this difference, however, riding in a carriage, or on horseback, does not increase the grievances when the prostate is affected; but it does so, in an intolerable degree, in cases of stone. It also generally happens, that the fits of stone come on at intervals, whereas the pain from a diseased prostate is neither so unequal, nor so acute.

At this present time, (September 1811,) there is a man in St. Bartholomew's hospital who suffers many of the complaints usually attending a stone in the bladder; he has been sounded, but no calculus can be discovered; and it is now ascertained that his symptoms are dependent upon a contraction situated some distance up the rectum. The stricture is so considerable, that the feces can only pass in a liquid form, and the introduction of bougies above a small size is quite obstructed.

Who would suppose that symptoms, exactly similar to those of a stone in the bladder, could proceed from the venereal disease, and be cured by mercurial treatment? Yet, such a fact have we recorded by Richerand, now an eminent surgeon at Paris. See *Notographie Chirurgicale*, tom. iii. p. 506, edit. 2.

Nothing, therefore, except sounding the patient, will give the surgeon certain information of the presence of a calculus in the bladder. The symptoms which prevail may excite strong suspicions of the nature of the case; but since they may proceed from so many other different causes, they are not alone a sufficient warrant for venturing on the performance of lithotomy. When the surgeon undertakes this important operation, he must know with certainty that there is a stone in the bladder, and such positive knowledge can only be acquired by actually feeling and hearing the steel instrument, called a sound, strike against the foreign body. Nay,

further, as the stone may be in the bladder to day, but be protruded to-morrow on the outside of the muscular coat of this organ, so as to become as it were encysted and incapable of extraction, "it is an invariable maxim among all prudent surgeons never to begin the operation of lithotomy until they can clearly and distinctly perceive the stone with the finger, or at least with the staff at the time when the patient is brought forth to be operated upon." If the calculus cannot be plainly felt at this period, the operation is not justifiable. The importance of this precept cannot be too highly appreciated, by every practitioner who values either his patient's welfare or his own reputation; for were a different line of conduct pursued, an opening might be made into the bladder, so that it might be found, and, unfortunately, the patient lose his life from the operation, which, however well executed, is never free from a serious degree of danger.

The method of sounding will be described in a future volume of this Cyclopaedia. See *SONDING*.

The stone in the bladder is a disorder that is to be regarded as more grievous the longer it has existed, and the older and more debilitated the patient is. The crisis is particularly afflicting when the severe pain in the kidneys renders it not unlikely that there may be at the same time other calculi in the substance of these organs.

A stone is seldom known to be in the bladder until it is too large to pass out through the urethra. Should a very small one be detected, we are recommended to try the effect of introducing a large sound or bougie, making the patient drink abundantly of some diuretic liquor, and desiring him first to retain his urine, and then expel it as forcibly as possible, at the same time that the sound or bougie is withdrawn. In this manner, it is conceived, the stream of the urine might sometimes carry the calculus outward. Default had it in contemplation to adapt the port-crayon pincers, invented for the urethra by Mr. Hunter, to a common catheter, for the purpose of taking small calculi out of the bladder. This project, however, would be attended with much difficulty, and the sides of the bladder would be liable to laceration in consequence of becoming pinched. Instruments made on this principle, however, are sometimes successfully employed for taking small stones out of the urethra.

Dissolution of stones in the bladder.—The possibility of dissolving stones in the bladder was a thing believed for a very long space of time, and even at the present day is a scheme not altogether abandoned. The dissolution has been attempted both by internal medicines, and by certain fluids injected into the bladder.

The knowledge of the composition of urinary calculi at once apprises us that, as they consist of very different materials in different cases, the same solvent cannot be applicable to all of them.

It is observed by Murray, one of the learned professors of chemistry at Edinburgh, that long experience has sufficiently established the advantage derived in calculous affections from the use of alkaline remedies; and as the calculi, composed of uric acid, are those which appear to be most abundant, it is supposed to be from the chemical action they exert upon it that the benefit is derived. Where the pure alkali is used, a real solvent power may be exerted; and it has been proved that the alkali is secreted by the kidneys, so as to render the urine sensibly alkaline, and even capable of acting on the calculus out of the body. Yet the solvent power is very inconsiderable, and the remedy at the same time proves so noxious, when taken to any considerable extent, that the formation of a calculus, even of small size, can perhaps be scarcely expected. The pain and irritation which

attend the disease, however, are considerably alleviated by their habitual use, and this even when the alkali is saturated, or super-saturated with carbonic acid, a circumstance with regard to which there appears some difficulty in giving an explanation, since the alkalies in this state have been supposed not to act on the uric acid. But, from the experiments of Dr. Egan (*Philos. Magaz.* vol. 23 and 24), this appears to be a mistake; though the relief obtained from the use of these may also be in part derived from the saturation of the other acid, whether phosphoric or acetic, which is likewise secreted; the urine is thus rendered less irritating, and the tendency to a deposition of uric acid diminished, all acids hastening the precipitation of this acid from the urine. It has accordingly been found, that under the use of alkaline remedies, the sediment of uric acid from the urine, so often abundant in cases of calculus, rapidly diminishes. The increase of the concretion is thus prevented, and the principal cause of irritation removed.

So far, therefore, professor Murray acknowledges that the alkalies may act as palliatives; but he contends, that it must be very doubtful if they can be given to such an extent as to exert an actual solvent power. Besides, there is an effect which may attend their continued use, especially in large doses. It has been remarked by Mr. Brande, that the phosphates of lime and magnesia are held in solution in urine, chiefly by its excess of acid; if this be saturated, therefore, by the use of an alkali, although the deposit of uric acid may be checked, that of the phosphates will be favoured, and it appears that it is principally from a deposition of these that a calculus in the bladder increases in size. Some cases, adduced by Mr. Home, appear to support this conclusion.

Lime, under the form of lime-water, has been employed as a solvent. The experiments of Dr. Egan have shewn, that lime-water acts with more energy than an alkaline solution of similar strength in destroying the aggregation of urinary concretions, and Murray found the same thing. The lime probably operates more upon the albumen or animal matter, which appears to serve as the cement or connecting substance, than upon the uric acid; and Murray thinks that in endeavouring to discover solvents for these concretions, our views ought perhaps rather to be directed to this operation than to the effect on the saline matter. If, says he, lime, when received into the stomach under the form of lime-water, can be secreted by the kidneys, as the alkalies unquestionably are, it would appear to be superior to them as a solvent. But when we consider the sparing solubility of lime, and the small quantity of it therefore that can be brought to the kidneys, the possibility of its secretion may be doubted. Mr. Brande has even supposed that, were it secreted, it would rather prove hurtful, by forming an insoluble compound with the phosphoric or carbonic acids, which are always contained in the urine. Murray owns this to be possible; but he argues that if the concretion of these substances into a calculus is owing principally to the action of the animal matter, since this must be prevented, any deposit would be discharged, and perhaps the aggregation of an exsting concretion be destroyed. Under this view, Murray thinks that the proper practice would be the exhibition of alkali and lime together, the former neutralizing the excess of acid in the urine, and allowing the latter to exert its power; and it deserves to be remarked, that the celebrated Stephens's remedies are a combination of this kind. Calculi, composed of oxalate of lime, phosphate of lime, or phosphate of magnesia and ammonia, not being soluble by alkalies, the object has been attempted by the action of weak

acids, like that of lemons. It is questionable, however, whether any acid can be given so as to communicate to the urine a solvent power. Besides, though an acid were to remove the phosphates, or at least prevent their deposition, it might promote the formation of uric acid concretions. If, however, the lime-water and alkalies, by operating on the animal matter of calculi, tend to destroy their aggregation, these remedies may prove somewhat useful in all the varieties of stone. See Murray's *System of Chemistry*, vol. iv. p. 651, et seq.

Setting aside all chemical reasoning, we are sorry to be obliged to confess that practice does not justify any strong hopes of the sufficient efficacy of internal medicines to dissolve stones in the bladder. But though lithontriptics are not equal to this effect, they certainly alluage the severity of the symptoms, which is a benefit of infinite importance to the afflicted.

Medicines conveyed into the stomach having failed to dissolve urinary calculi, various practitioners have placed considerable expectation in the plan of introducing a solvent injection through a catheter directly into the bladder. It will be seen, from the article CATHETER in this work, that the ancients knew how to introduce fluids into the bladder many centuries before Mr. J. Foss published upon the "*Vesicæ Lotura*." Fourcroy and Vauquelin ascertained, that a ley of potassa or soda, not too strong to be swallowed, softens and dissolves small calculi, composed of the uric acid and urate of ammonia, when they are left in the liquid a few days. They have proved that a beverage, merely acidulated with nitric or muriatic acid, dissolves with still greater quickness calculi formed of the phosphate of lime, and of the ammoniacal magnesian phosphate. They have made out that calculi composed of the oxalate of lime, which are the most difficult of solution, may be softened and almost quite dissolved in nitric acid, greatly diluted, provided they are kept in the mixture a sufficient time. We know then liquids that will dissolve calculi of various compositions; but much difficulty occurs in employing them effectually in practice. For although we can easily inject them into the cavity of the bladder, this organ is so extremely tender and irritable, that it cannot bear the contact of any fluid, except that which it is destined by nature to contain, and the action of such liquids upon it as would be necessary to dissolve a stone in its cavity would not fail to produce sufferings which no man could endure, and the most dangerous and fatal effects on the bladder itself. Another objection to this experiment is the ignorance in which the practitioner is with regard to the chemical composition of calculi before their extraction, and of course the impossibility of knowing what solvent ought to be injected. Upon this reason, however, it is unnecessary to lay much stress; for were the previous more weighty objection done away, the latter difficulty might perhaps be obviated.

Desirable, therefore, as an effectual lithontriptic is, as it would be the means of freeing the afflicted from the terrible sufferings occasioned by a stone in the bladder, and of removing all occasion for a painful and hazardous operation, it is a melancholy truth that, notwithstanding every expectation, arising either from chemical reasoning, from quackish boastings, or from the palliation and temporary relief really obtained, we have no practicable means of dissolving a stone in the living bladder. Until this grand discovery is made, lithotomy will ever be an indispensable operation, and the views of enlightened surgeons should all be directed to render it as free as possible from pain and dangerous consequences.

We shall now endeavour to give an impartial description of the principal methods of cutting for the stone, beginning with such as are most ancient, and concluding with those which have been very recently suggested.

Of the Apparatus minor, Methodus Celsiana; or cutting on the gripe.—The operation which we are about to explain is by far the oldest species of lithotomy, its antiquity extending back to time immemorial. Although we are indebted to the immortal Celsus for the first description of it, he was in all probability not the original inventor. We learn from history, that Hippocrates made his pupils take an oath that they would never attempt to cut for the stone; and, according to Florus, the Latin historian, the son of Alexander, king of Syria, perished, when about ten years of age, in consequence of this operation, which had been villainously undertaken, though there was no stone in the bladder. It is plain then, that, long before the time of Celsus, the ancients were acquainted with some mode of lithotomy, which we may infer was what is now called the apparatus minor. This last appellation, deduced from the small number of instruments required, was not employed till the commencement of the sixteenth century, the period when another method, named the apparatus major, had its rise. The phrase of “cutting on the gripe,” came into use in consequence of the surgeon having to cut upon the stone, while he grasped it, with his fingers introduced within the rectum.

The manner of doing the operation is this. You first introduce the fore finger and middle finger of the left hand, dipped in oil, up the anus, and pressing softly with your right hand above the os pubis, endeavour to bring the stone towards the neck of the bladder; then making an incision on the left side of the perineum, above the anus, directly upon the stone, you turn it out through the wound, either with your fingers or a scoop. Sharp on the Operations, chap. 18.

Many objections have been urged against this method by surgical authors.

1. In the first place it is not applicable to adults, as, in such patients, it would seldom be found possible to fix the stone by the fingers introduced within the rectum. Celsus confined the operation to subjects between the ages of nine and fourteen, which is rather extraordinary, as it is more easy of performance the younger the child is, though certainly it hardly admits of being done at all after the patient is more than fourteen.

2. The same parts are not always cut, as this depends very much upon the degree of force with which the stone is made to project in the perineum, and the least inclination to one side or the other must also make a considerable difference. When the incision is favourably executed, the parts cut are nearly the same as those divided in the modern and most approved mode of operating. But as the operator always cuts directly on the projecting stone, the parts exposed to the knife must vary in different cases for the reasons already alleged; and the records of surgery prove, that in performing the apparatus minor, the urethra may be quite detached from the prostate, or the vesicula seminalis and vas deferens be injured.

3. The neck of the bladder must suffer very much from rough stones, when considerable force is exerted in pressing them towards the perineum. That this is not mere conjecture, is confirmed by the observations of Celsus, from whose account it plainly appears that, in his time, many actually died from the violence done to the bladder, in endeavouring to bring the stone forwards, though the operators failed in their attempt, and the patients were not cut. Fabricius Hildanus was well acquainted with all the uncertainty

of cutting on the gripe, and he endeavoured to improve the method by introducing a staff through the urethra into the bladder, so that the operator might avail himself of the guidance of this instrument in making the required opening for the extraction of the stone. Fabricius brought the stone into the neck of the bladder with his finger, which were passed up the rectum, just as Celsus describes, and then, guided by the staff, made such a division of the prostate and neck of the bladder, as sufficed for the passage of the calculus outward. The extraction was accomplished with a sort of hook.

The apparatus minor, done in this manner, is by no means an ineligible operation for young male children, when the surgeon can easily grasp the stone with his fingers, from within the rectum. We do not mean to say it is rash to make an incision into the bladder with a common scalpel, guided by a staff, even though the stone cannot be fixed with the fingers, only the operation would then not be that of “cutting on the gripe,” to which, at present, our remarks are limited. We agree entirely with Mr. John Bell, who, in commending the improved Celsian method, as practised by Fabricius, takes occasion to remark, that you cut upon the stone, and of course make, with perfect security, an incision exactly proportioned to its size. There is no difficult nor dangerous dissection; no gorget, nor other dangerous instrument, thrust into the bladder, with the risk of its passing between that and the rectum; you are performing, expressly, the lateral incision of Raw and Cheselden in the most simple and favourable way. John Bell's Principles of Surgery, vol. ii.

Of the Apparatus major, or Scēio Mariana.—This method of cutting for the stone was named *Apparatus major*, from the great number of instruments used in the operation; and *Scēio Mariana* from one Marianus, who published the first description of it. Johannis de Romanis, a surgeon at Cremona, was the inventor about the year 1523, or 1525, though the exact period is very uncertain. Marianus was the scholar of Romanis, and having learned his master's art of operating, printed an account of it in Latin. The date of this treatise seems rather undetermined, Douglas making it 1522, Sharp 1524, and Sabatier a period subsequent to 1540.

Experience has repeatedly proved, that, in consequence of the shortness and dilatable nature of the female urethra, calculi of considerable size may be extracted from women without employing any cutting instruments at all. The passage may be gradually dilated, so as to allow the forceps to be introduced into the bladder, and the stone taken hold of, and extracted. The adaptation of this plan to male patients was the principal object of the Marian operation. With this view, an incision was made into the urethra at the bulb. That part of the canal which was situated between the wound and the neck of the bladder, being short and somewhat straight, was thought to bear a resemblance to the female urethra. Instruments were therefore passed into the opening, for the purpose of dilating such portion of the urethra, sufficiently to let the forceps be introduced, and the stone extracted. It was never recollected that the male urethra, where it is surrounded by the prostate gland, could not rightly be compared with the meatus urinarius of the female, since it was totally incapable of being dilated in a degree at all adequate to the objects in view. Hence most dreadful injury was done to the part, which, instead of yielding, were torn and confused in a manner shocking to relate.

There were various modes of executing this barbarous operation; the following particulars, we presume, will at

once satisfy the curiosity of the professional reader, and make him for ever abhor a method that is so repugnant to the principles of good surgery, and the dictates of humanity and common sense.

The patient was bound in the position usually adopted in the more modern methods of cutting for the stone. After an opening had been made into the urethra, close behind the bulb, much in the same way as is practised in the performance of the lateral operation, the surgeon used to introduce into the bladder, along the groove of the staff, an instrument resembling a strong iron probe, and called a male conductor. The staff was then taken out of the urethra, and the female, or grooved conductor, guided along the male one into the bladder. By means of these two implements, endeavours were next made to dilate the undivided portion of the urethra, and the neck of the bladder, sufficiently to enable the operator to introduce the forceps. After much time spent in stretching the parts, the forceps were passed into the cavity of the bladder, and the stone was drawn out, though, in general, not without considerable force and violence. Sometimes the dilatation was attempted with a blunt gorget; sometimes by expanding the blades of the forceps. Many operators used different instruments for the purpose, called dilators. Franco, Tollet, the Collots, and Alghisi, employed them.

When we reflect that, in this method, the prostatic portion of the urethra was left undivided, a part which is very incapable of much dilatation, we must know that the opening through which the forceps was introduced, and the stone taken out, was not formed by the elastic yielding of the parts; but by an actual laceration of them, attended with an immense deal of contusion and violence. In what a degree such mischief must have taken place in cases where the stone was of large size, is easily conceivable. We cannot wonder, therefore, at the severe, and frequently fatal, consequences of so barbarous an operation. The patients very often perished of inflammation of the bladder and abdominal viscera. An extensive effusion of blood in the scrotum, abscesses and fistulae in perineo, incontinence of urine, and impotency, were also common consequences. With these facts before us, we must feel surprise that the operation of Marianus should have been practised for the space of two hundred years, by some of the most distinguished surgeons in Europe, as Paré, Le Dran, Le Cat, Méry, Morand, Maréchal, Raw, &c.

The foregoing account will serve to convey a general notion of the apparatus major, so famous a subject in the history of lithotomy; but such readers as wish to be acquainted with all the different modes in which it was practised by the old surgeons, ought to consult *De la Médecine Opératoire*, par Sébaste, tom. ii.; and the *Principles of Surgery*, by Mr. John Bell, vol. ii. Very clear and more concise descriptions of the apparatus major may be found in Sharp's *Treatise on the Operations*, or in Bertrandi's *Traité des Opérations*.

Apparatus altus.—This is the technical name given to the method in which the stone is extracted from the bladder, through an incision practised in the fundus of this organ from above the pubes. The inventor of this mode of cutting for the stone was Pierre Franco, a surgeon at Fourmies, in Provence. He was led to attempt the operation, from having under his cure a child with a calculus, that could not be brought towards the perineum on account of its magnitude. Although the little patient suffered much in operation afterwards, the wound healed, and a perfect recovery followed. The prosperous event of this case, it seems, was not enough to convince Franco, that wounds of

the bladder were less perilous than he apprehended them to be, and at the same time that he details the particulars of the plan he pursued, he cautions us not to imitate him. See *Traité des Hernies*, Lyon, 1561.

Doubtless, the advice delivered by Franco intimidated his contemporaries; for we find no notice taken of the apparatus altus again till 1597, when this plan of operating was recommended by Rossetti, a well-informed and judicious physician, in a work entitled "*Partus Cæsarius*." This author represents it as the best and safest mode of cutting for the stone, but though he had clear ideas of the possibility of the method, his observations are not supported by any actual experience of his own. Afterwards, the operation was at first reprobated, and then adopted by Fabricius Hildanus, in cases where the stone was of considerable size. It was commended by Riola in his remarks upon the anatomy of Vellingius; and Simon Piètre, a physician at Paris, wrote a memoir in favour of the operation in the year 1635. Since this period, the apparatus altus is mentioned by numerous writers, though few surgeons ventured to perform it. However, it is said to have been practised by Bonnet, an old surgeon of the Hôtel-Dieu. At length the faculty of Paris recommended the parliament to authorise some additional experiments in regard to the apparatus altus, and Francis Collet was appointed to make the requisite trials of the operation. The result was, that, in his opinion, the method was attended with great danger, and, consequently, the practice in France was prohibited.

The apparatus altus, however, was not every where abandoned. Proby, a surgeon at Dublin, practised it for the purpose of extracting from the bladder of a young woman a long pin, covered with a stony incrustation, which he was unable to get out through the urethra. (See *Phil. Trans.* for 1700.) Groenvelt, a Dutchman, who, in 1716, published a treatise on lithotomy in English, says, that he was under the necessity of removing a stone from the bladder by cutting above the os pubis. At length, in 1718, Dr. Douglas wrote a dissertation in praise of this method of operating, which was soon afterwards put to the test of experiment by his brother, the surgeon, who was imitated by several English and German practitioners. In consequence of these proceedings, the operation was again revived in France, and it was practised at St. Germain-en-Laye by Berryer, a surgeon of that town, and by S. F. Morand, at the Hôtel des Invalides. The latter attempt proved unsuccessful. An account of both these cases was published by Morand in 1727. The operation was afterwards much on the decline in France, and probably would have been totally given up, had not a new method of performing it been proposed by Fèvre Côme. See *Nouvelle Méthode d'extraire la Pierre de la Vessie Urinaire par dessus le Pubis*, à Paris, 1779.

In the apparatus altus, the design of the surgeon is to make an opening into the anterior part of the bladder above the os pubis. The patient is to be placed upon a table, or bed of suitable height, with his legs reaching over the edge and resting upon a stool. Two assistants are to keep the patient's body and arms steady, while two others take hold of his thighs. The patient's trunk should be somewhat bent forwards, in order to relax the abdominal muscles; but it is highly necessary for the pelvis to be rather more raised than the chest, so that the intestines may not gravitate towards the bladder, and by depressing this viscus, make it more difficult to be got at. Besides, raising the pelvis above the level of the thorax prevents the stone from falling towards the neck of the bladder, from which situation the extraction would be less easy.

LITHOTOMY.

The operation has been executed in several ways.

The most ancient mode was that of cutting directly upon the stone, which was pushed upwards and forwards, towards the lower and front part of the abdomen, by two fingers introduced into the rectum. Franco operated in this manner, and he was imitated by Bonnet, Heister, &c. While an assistant pushes the stone upward, the surgeon is to make an incision through the skin just above the os pubis, and through the lower portion of the linea alba: he is then to puncture the bladder, enlarge the opening from above downwards with a probe-pointed crooked bistoury, and, lastly, take out the stone with a pair of forceps.

Rosselli was the inventor of a particular method. In the apparatus altus, it is an object of the greatest consequence to make an opening into the bladder without wounding the peritoneum. Hence Rosselli adopted the plan of distending the bladder with warm water, which was injected through a catheter placed in the urethra, and thus made the viscous rise to a convenient height above the pubes. The fluid was injected in the most slow and gradual manner, in order that it might give as little pain and uneasiness as possible. The quantity introduced was, in general, from eight to sixteen ounces. Some authors object to an injection, and recommend the patient to retain his water till the requisite distention of the bladder has taken place. When this receptacle had been filled, the catheter was withdrawn, and the fluid kept from escaping by an assistant, who compressed the urethra. The integuments and linea alba were then cut, as in Franco's method. A puncture was next made in the bladder with a bistoury, having its edge turned towards the pubes; and the surgeon with his left index finger, which was directly passed into the opening, kept the bladder from descending, while he finished the incision of that viscous, by cutting from above downwards below the os pubis. The bladder was still kept up with the index finger, until the stone was extracted with the forceps. In order to be sure of having the bladder distended, and to be able to introduce more injection if necessary, Mr. Middleton used to keep the catheter in the urethra till the incisions were completed. On the other hand, Douglas was in the habit of cutting down to the bladder before he introduced the catheter.

The apparatus altus has been objected to as unadapted to persons who are either inclined to be fat, or whose bladders are not capacious. Unfortunately, in the generality of stone-patients, the bladder is much contracted. The introduction of the injection has likewise been found a painful and uncertain proceeding: for, very often, a sufficient quantity could not be got into the bladder, so that in operating there was some risk of wounding the peritoneum. The method has also been accused of frequently giving rise to an extravasation of urine, and sloughing and abscesses in the pelvis, in consequence of the greater facility with which that fluid escapes through the wound of the bladder than through the urethra. These unpleasant events have been said to take place the more easily, as when the bladder contracts, it descends behind the os pubis, and the wound in it no longer continues opposite to that in the linea alba and integuments. Keeping a catheter in the bladder, or the patient in an horizontal posture, has not, it is said, availed in preventing the frequency or fatality of such mischief.

However, Frère Côme's method of performing the apparatus altus, which we shall hereafter notice, is represented by the French surgeons as being free from the preceding inconveniences. When the account of this form of the apparatus altus has been read, we entertain little doubt that the operation will appear, to all good judges, to have merit. Frère Côme is said to have cut nearly a hundred patients, in the

manner alluded to, with almost uninterrupted success. The plan has the advantage of enabling a surgeon to extract larger stones than can be taken out of the bladder by any other method, as the incision may be enlarged in proportion to their size, and the bladder is here more yielding than in the vicinity of the prostate gland. Nor is the passage of a large stone here resisted by any bony obstacles, as in other modes of operating. See Sabatier's *Médecine Opératoire*, tom. ii. p. 51.

It must be confessed, that some difficulty might arise in case the stone were to break, as the fragments could not be so easily taken out as in other methods. We are to remember, however, that this accident is less likely to happen, because the parts through which the calculus has to pass are all soft and yielding. Were it to take place, the larger pieces of the calculus might be extracted by means of proper forceps, and the smaller ones would be carried out with the urine through the tube in the perineum.

This method, against which the records of surgery appear to adduce no serious objections, founded on as positive experience, has been entirely abandoned. Want of simplicity is alleged against it; but we think without much reason, for the operation, as will be seen from the description, is not difficult; nor is the number of instruments immoderate. If, what Richter mentions be true, that Frère Côme cut nearly a hundred patients in this way with almost invariable success, the justification of further trials cannot be doubted. The method, as modified by Deschamps, who, instead of cutting the perineum, perforated the bladder from the rectum, has received the high sanction of Dr. Thomson of Edinburgh. See *Edinburgh Surg. Journ.* N. 15.

Lateral operation.—Since the ill consequences of the apparatus major were chiefly owing to the distention, contusion, and laceration which the membranous and prostatic portions of the urethra, and the neck of the bladder itself suffered, the idea of preventing such mischief, by cutting these parts to a sufficient extent, seemed almost a certain and natural effect of any reflection bestowed on the subject. The making of such an incision constitutes all the particularity of the lateral operation; but as the lower side of the urethra cannot be divided far enough without the rectum being wounded, the cut is directed sideways, from which circumstance the name of the method is derived.

The lateral operation being that which, under various modifications, has now taken the place of every other method of cutting for the stone, it seems proper to give some account of its origin and progressive improvement, and of the different modes of executing it, with gorgets and a variety of lithotomes and knives.

In September, 1667, a sort of monk, named Frère Jacques de Beaulieu, went to Paris, taking with him numerous certificates of the many cures which he had accomplished in sundry places, and announcing his desire to teach the surgeons of that city a new method of cutting for the stone. He paid his respects to Mareschal, then principal surgeon to La Charité, and requested leave to operate upon some of the patients in that hospital. Mareschal, however, did not think proper to trust the living to a man, of whose qualifications he was entirely ignorant, and all that Frère Jacques could get granted, was permission to exhibit his mode of operating upon a dead body. The result was, that his plan was not considered advantageous, and, dissatisfied with the reception he had experienced, he quitted Paris in October, and repaired to Fontainebleau, the seat of the court. Here he cut for the stone a lad, who, in three weeks after the operation, was seen walking quite well about the streets.

LITHOTOMY.

Frère Jacques put his patients under no preparatory treatment before the operation; he placed them on the edge of a table, with a pillow under their heads, and with their legs and thighs bent and separated from each other, in such a way, that their heels approached their buttocks. He did not bind his patients in this posture; but made some strong assistants hold them. Then, having introduced into the bladder a round, solid, ungrooved staff, he took a long narrow knife, and made an oblique incision in the perineum, along the internal part of the tuberosity and ramus of the ischium, cutting from below upwards. In this way, he cut all the parts which presented themselves, without taking out the staff. He now introduced his finger into the wound, in order to ascertain the situation of the stone, and enlarged the internal opening with an instrument much like a scratching knife, but which only had one cutting edge. On this instrument, which he called his conductor, he passed the forceps into the bladder. The solid staff was then withdrawn from the urethra, and the calculus extracted. Lastly, some linen dipped in a mixture of oil and wine was applied to the wound, and the operator took final leave of his patients, telling them, that the operation was done, and that God would complete the cure.

Frère Jacques' success at Fontainebleau changed the public opinion so much in his favour, that it was determined to let him operate, in the ensuing spring, on the patients in the Hô tel Dieu and La Charité. He was directed, however, to make some previous trials of his method upon the dead subject in the presence of Méry, who was ordered to furnish a report on the matter. Méry's first declaration was quite favourable to Frère Jacques, as it stated, that the neck and body of the bladder were cut instead of being dilated, as they were in the ordinary method at that time; that as the stone was extracted at the widest part of the arch of the pubes, the symptoms were likely to be milder; and, among other circumstances, that the internal parts were less exposed to be torn and bruised. Méry thought Frère Jacques' instruments not so eligible as those in previous use, and particularly objected to the staff, which, having no groove, served as a very indifferent guide to the knife.

Under Méry's inspection, Frère Jacques made further trials of the new method on dead bodies, and a second report, drawn up by the former, was much less propitious than that which had been previously delivered. But neither this circumstance, nor some unfortunate operations which Frère Jacques had lately performed at Versailles and Paris, led to a rejection of the new plan; for forty-two stone patients, in the Hô tel Dieu, and eighteen in La Charité, were now put under his care. Nothing could surpass the general eagerness to see him operate. There was not a physician, nor a surgeon, who was not proud of being his assistant. In short, so vast was the concourse of spectators, or rather, of those who wished to be such, that guards were found necessary to preserve order. Of the above sixty patients, twenty-three died. Only thirteen were perfectly cured, and even in some of these the wound is said to have afterwards broken out again. The other twenty-four remained in the hospitals; some with an incontinence of urine; others with fistule; and all in a reduced state, from which they are said to have never recovered. On examining the bodies of the deceased, it appeared that, in some instances, the fundus of the bladder was wounded, while in others, the neck of this viscus was entirely separated from the urethra; that, in women, the vagina was constantly pierced in two opposite places; that, in both sexes, the rectum was frequently opened; and that, in all cases, the parts were terribly lacerated, in consequence of no

guide for the knife, and no conductor having been employed.

The ill success of Frère Jacques' operations did not produce similar sentiments in every mind. Felix and Fagon, in France, thought that his method had merit, and that, when improved in particular points, which they suggested, it might be made far superior to any other mode of cutting for the stone. Frère Jacques profited so much by their advice, that, in 1699, he operated on about sixty persons, most of whom got quite well. He spent the ensuing winter at Versailles, as an inmate with Fagon, and there repeatedly practised lithotomy on the dead subject. Duverney dissected the bodies, and though he found Frère Jacques' method far preferable to the apparatus major, which was then the only other plan in use, he was of opinion with Méry, "that the staff would be better with a groove, as its round and solid form was ill suited for the guidance of the knife." Frère Jacques, ever ready to receive instruction, lost no time in adopting the improvement. He had new staffs constructed, and continued to employ them the rest of his life.

In the spring of 1701, this celebrated lithotomist cut thirty-eight patients for the stone at Versailles. These all recovered. Fagon, who was afflicted with the disorder, could not resolve to put himself under the care of the new operator; but was operated upon and cured by Maréchal. Frère Jacques, somewhat piqued at this circumstance, quitted Versailles, with the intention of never returning thither; but, in 1702, he was induced to re-visit the place at the instance of the Maréchal de Lorges, who was afflicted with the stone, and under whose roof were lodged twenty-two poor patients with calculi. These were all operated upon with success; but the Maréchal, whose bladder contained fungous excrescences, and seven small stones, the extraction of which was tedious, died the day after submitting to the operation. In consequence of this accident, Frère Jacques determined to go into Holland. Here his success must have been very considerable; for he was thrice engraved; and at Brussels, whither he was sent by the magistrates of Amsterdam, a medal was struck in honour of him, with this inscription: *Pro servatis civibus*. The motto of one of the engravings is the following passage from Cicero: *Ægri, quia non omnes convalescant, non illis ars nulla medicina est*. This alludes to the many hostile criticisms which had been issued against him.

In 1712, Frère Jacques, being sixty years of age, returned to Besançon, his native place, where he soon afterwards died.

While he was at Amsterdam, his mode of operating had been observed by the famous Row, who at once perceived, that the method was infinitely preferable to the apparatus major, and who, after some trials on the dead subject, put it in practice on the living. Row's success exceeded every thing heard of before; besides extracting the stone with the utmost ease, he cured all his patients without exception. His reputation spread every where. Surgeons flocked from all parts to Amsterdam, in order to see him operate and receive his instructions. He cared not how many spectators he had; but no one could prevail on him to divulge the particulars of his plan. To every solicitation on this point, his usual reply was, "*Celsum legitote*," which seems to hint, that he was in the habit of cutting the same parts as were divided in the ancient operation of the apparatus minor. It is asserted, that he cut for the stone 1540 patients, and (what is almost incredible) they are all stated to have recovered, so that there was never any opportunity of dissecting the bodies of any of his patients.

LITHOTOMY.

It was for a long while presumed, that Raw made an opening into the bladder, without touching the neck of this viscus, or cutting the prostate gland. This, at least, was the sentiment of Albinus the father; but, in latter times, the general conclusion has been, that Raw must have divided these parts.

After Raw's death in 1719, experiments were made, in order to ascertain his mode of performing lithotomy. Among others engaged in this object was Cheselden, who, when the bladder was distended with an injection, succeeded in making an opening into this viscus, without injuring its neck. Having tried this plan, however, on some of his patients, he soon found, that it was very liable to be followed by a fatal extravasation of urine in the pelvis, and, consequently, he renounced it for ever. His experiments were still carried on, and at length he was convinced, that in operating with the instruments, and in the manner of Raw, as described by Albinus, it was impossible to make an opening into the bladder, without cutting the membranous part of the urethra, and the prostate gland. Cheselden now stopped his investigations, and directed all his abilities to the easy accomplishment of such an operation. The knife, commonly employed on other occasions, seemed to Cheselden much more convenient than the pointed lithotome used by the Dutch surgeons. Instead of the male and female conductor in use with Raw, Cheselden preferred a blunt gorget for guiding the forceps into the bladder; but he altered the handle, which, instead of representing a sort of cross, was now oval, and made to incline to the left.

Having abandoned the method imputed to Raw by Albinus, Cheselden tried a second plan, which was as follows: the patient being placed in the posture usually chosen for lithotomy by modern operators, a grooved staff was introduced into the bladder. The handle of this instrument was inclined towards the right groin, and firmly held by an assistant with one hand, while, with the other, the scrotum was supported. The skin of the perineum having been made tense with the operator's left thumb, a free oblique incision was made with a convex edged scalpel, much in the same way as is commonly done at the present day. The slit was next deeply cut through. The left index finger was then introduced into the upper angle of the wound, and the groove of the staff being felt through the parietes of the urethra, a cut was made into this canal. The assistant that had the care of the staff, was now directed to draw its concavity upward as closely as possible under the arch of the pubes, away from the rectum. All that remained to be done, was to divide the membranous part of the urethra and the neck of the bladder. This was executed by pulling the point of the knife along the groove of the staff, under the guidance of the left index finger, which, in this step of the operation, was kept on the back of the scalpel. Having reached the prostate gland, the incision was completed by the knife being moved downwards and outwards, with its edge turned towards the tuberosity of the ischium.

The left index finger, remaining in the wound, served to guide the beak of the blunt gorget into the groove of the staff. The operator now took hold of the handle of this last instrument, and, after bringing it downwards and forwards, conducted the gorget into the bladder. The staff was withdrawn, the forceps introduced along the concavity of the gorget, and the stone extracted. Such was Cheselden's second method. It was this operation which Merand gave an account of to the French surgeons, after seeing it performed during his visit to England at the expense of the Royal Academy of Sciences; and it is par-

ticularly worthy of notice, that foreign surgical writers seem unaware, that Cheselden afterwards gave the preference to a third plan of operating, which has been described by Douglas in his second History of the Lateral Operation, published 1731.

We are not very well acquainted with the reasons which led Cheselden to abandon his second method. He had, however, candidly confessed to Merand, that in pushing the knife backwards along the groove of the staff, he had in two instances wounded the rectum. Besides, it is conjectured, that the incision of the prostate gland was often too small for the free transmission of the stone.

Cheselden's third, and what he considered as his best method of cutting for the stone, did not differ in point of principle from his second plan. The same parts were cut, namely, the membranous part of the urethra, and the prostate gland. The change consisted in a different mode of executing the incision, "which was now performed by moving the knife from behind forwards," instead of from before backwards, as in the second method.

The following is the description of Cheselden's last and most improved plan, as given to us by Douglas. "In performing the lateral operation, he makes the first, or outward incision, from above downwards; beginning on the left side of the raphe, or seam, betwixt the scrotum and the verge of the anus, almost as high as where the skin of the perineum begins to dilate and form the bag that contains the testicles, and from thence he continues the wound obliquely outwards, as low down as the middle of the margin of the anus, at about half an inch distant from it near the skin, and, consequently, beyond the great protuberance of the os ischium.

"The first or upper part of this incision is cut superficial; after that, 'he plunges his knife much deeper by the side of the rectum, and finishes it by drawing his knife obliquely towards himself.' These three motions may always be observed in his external incision; but the last is performed pretty much at random; his knife first enters the groove of the 'rostrated or straight part of the catheter, through the side of the bladder, immediately above the prostate;' and afterwards, the point of it continuing to run in the same groove, in a direction downwards and forwards, or towards himself, he divides that part of the sphincter of the bladder that lies upon the gland; and then he cuts the outside of one-half of it obliquely, according to the direction of the whole length of the urethra that runs within it, and finishes his internal incision by dividing the muscular portion of the urethra on the convex part of the staff."

The second and third of Cheselden's methods, then, resembled each other in the parts cut; but the first and third were essentially different, notwithstanding the knife was in each of them plunged at once into the body of the bladder behind the prostate gland. Cheselden, in his first operation, only imitated Frere Jacques and Raw, and passed his knife into the bladder betwixt the vesicula seminales and tubercle ischii. He stopped at the back part of the prostate gland. All his incision lay behind this gland. "He cut the body of the bladder only." But, in his last operation, he cut no part of the body of the bladder; "he introduced his knife close behind the prostate gland, and in drawing it towards him, he of course cut only the neck of the bladder where it is surrounded by that gland." John Bell's Principles, vol. ii. p. 153.

In operating after the manner ascribed to Raw, Cheselden lost four patients out of ten; but in pursuing his own improved method, his success was most brilliant, for, of fifty-two patients whom he successively cut for the stone, all were saved.

saved excepting two; and it is well known, that out of two hundred and thirteen persons, of all ages, constitutions, &c. on whom he operated, only twenty died. What lithotomy of the present day can boast of equal success? We have seen lithotomy performed rather frequently with cutting gorgets of different descriptions, in the manner that has been of late years most prevalent. Out of every seven or eight operations, at least one has had a fatal termination. We make this statement with some degree of confidence, as we know it might be confirmed by the most respectable and impartial evidence. To what then are we to refer the few failures which Cheselden experienced, and the vast number of deaths consequent to the present common plan of cutting for the stone. The reply, in our opinion, is obvious. Cheselden made an ample and direct incision into the bladder with a sharp knife, the instrument, of all others, the best calculated for effecting a clean smooth division of the parts, without any laceration, contusion, or other additional injury. The moderns often make their external incision too small, and too high up, while the internal cut, which is executed with a gorget, is almost always too diminutive for the easy passage of any calculi above a very moderate size. The difficulty of extraction must evidently be increased by the external wound being considerably higher up, than the internal division of the prostate gland and neck of the bladder, since the passage through which the stone must be drawn out, besides being too small, does not lead directly into the cavity of the bladder. Cheselden, in using the knife, had occasion to exert no force nor roughness. The moderns, whose gorgets are sometimes very badly constructed, are often under the necessity of pushing such instruments most forcibly, ere the opening into the bladder can be made. The violence and injury which the parts must thus suffer, in addition to their simple division, require from us no comment. Cheselden, having the advantage of a free and direct opening into the bladder, never bruised and injured the interior of this viscus by tedious searches after the stone with the forceps; nor when he had grasped the foreign body, did he ever bruise and lacerate the parts in drawing it out. His constant plan, on first introducing the forceps, was to search gently for the stone *with their blades shut*. When he had got hold of the stone, he used to extract it "with a very slow motion, in order to let the parts yield as much as possible." On the contrary, the moderns, generally having too small an opening, are often obliged to introduce and withdraw the forceps twenty or thirty times before they can accomplish the extraction of the stone. Desirous of shortening the business, they are guilty of manual roughness and violence; and not only the bladder, but the parts through which the stone has to pass, are dreadfully bruised and injured. Some operations which we have witnessed have been so long, and executed with such awkwardness and want of gentleness, that we cannot help suspecting, that the bladder must actually have been in a state of inflammation before the poor patients were removed from the operating table.

Cheselden undoubtedly was one of the most expert and successful lithotomists that ever lived in any country, and his mode of operating, which is fully explained to us, ought, in our opinion, never to have been abandoned for the employment of cutting gorgets.

Of the best way of executing the lateral operation with cutting gorgets.—We suppose it must have been ignorance of anatomy, joined with timidity and want of judgment, that could induce surgeons to give up so excellent a plan of operating as that which was invented and practised by Cheselden; for admitting that it is somewhat easier to make the lateral incision with a cutting gorget, there is yet a

more interesting and weighty matter for consideration, namely, whether the recoveries after the latter operation are, upon the whole, as numerous as those which followed Cheselden's method. This eminent surgeon, as we have already noticed, cut for the stone fifty-two patients in succession, of whom only two died. No surgeon of the present day, in the habit of using a cutting gorget, can boast of success at all equal to this. Our observation tends to the conclusion, that about one out of every seven or eight patients cut for the stone, with some kind of sharp gorget, falls a victim to the operation. According to our sentiments, a surgeon should not regulate his conduct so much by the facility, as the success of any plan; and a little more trouble and difficulty ought to be no objections, where they serve to give the patient a greater chance of preservation. We know that a man cannot imitate Cheselden, without having a requisite knowledge of the anatomy of the parts in the perineum, and about the neck of the bladder. We can conceive at the same time, that a person might learn to operate mechanically with a gorget, and yet be totally unacquainted with the structure and situation of the parts interested in the operation. It is this removal of all occasion for study and application, that has had more effect, than any thing else, in keeping up the present system of doing the office of the knife, with that very objectionable instrument a cutting gorget.

The patient is to be placed at the edge of a firm table, and the staff is to be introduced into the bladder.

Then two garters, each about two yards long, are to be doubled, and put, by means of a noose, round the patient's wrists. The patient is now to be desired to take hold of the outside of his feet with his hands, in such a manner, that the fingers are applied to the soles, and the palms to the insteps. The two ends of the ligature are then to be carried round the ankle, next over the back of the hand, and under the foot. Lastly, they are to be tied. In this manner, each hand and foot may be securely connected together, and the patient is fixed in the position the best suited for the operation.

The staff, the first instrument with which the surgeon has any concern, is in fact nothing more than a director, adapted in shape to the course of the urethra, and furnished with a groove for guiding a cutting instrument into the bladder. (See *Surgical Plates*.) It is shaped very much like a sound, or catheter. However, it is generally somewhat longer and more curved, and while the handle of a sound is as smooth and highly polished as possible, that of a staff ought to have a rough surface, in order that it may be held with greater steadiness and firmness. Two advantages arise from having the staff sufficiently curved; *viz.* its convexity is more plainly distinguishable in the perineum; and on depressing the handle of the instrument, that part of the groove which is at the neck and within the cavity of the bladder, may be more readily made to assume a direction corresponding to the axis of this viscus. The utility of the length of the instrument is very obvious, as the operator is thereby less liable to suppose the extremity of the staff to be within the bladder, when it is not so; and it is plain, that the groove should always extend beyond the beak of the gorget, even when the latter instrument has been pushed as far as the operator judges requisite.

An assistant is to hold the staff, making its convexity prominent in the perineum, by pressing the whole instrument downwards, and inclining its handle towards the patient's abdomen. The person who has charge of the staff, should also turn the groove a little towards the left side of the perineum,

LITHOTOMY.

neum, and raise the scrotum with his left hand, in order to expose the perineum completely to the surgeon's view.

The next consideration is the manner of making the external incision. A most common error is that of beginning the cut too high up. Nearly all the old surgeons commit this fault, by commencing the incision over the bulb of the urethra. This practice is above all things disadvantageous, especially when the operator makes the outward wound rather too small. Suppose, for instance, that the surgeon begins the incision as high as the bulb of the urethra, and does not carry it sufficiently far downwards; and that he next divides the prostatic gland and neck of the bladder with the gorget. Now, on attempting to take out the stone, the external part of the wound is too high, in regard to the internal portion; and the passage, through which the stone is to be extracted, not being straight and direct, as much impediment to the extraction is thereby occasioned as from the circumstance of the wound being too small. We are decidedly of opinion, that "a free and direct opening for the passage of the stone ought always to be made in the operation of lithotomy;" and that the fatal termination of numerous cases is entirely owing to the wound not being sufficiently ample and direct. The laceration of the parts, which must happen under such circumstances, is too frequently productive of peritoneal inflammation, the most alarming consequence of the operation. Nothing has a greater tendency to render the wound indirect, than making the incision through the skin too high up; or, in other words, so high as to interest the bulb of the urethra.

On the contrary, the wound should commence over the membranous part of the urethra, at the place where the operator means to make his first cut into the groove of the staff; and the incision is to extend about three inches obliquely downwards, to the left of the raphe of the perineum. The point to which it ought to be directed, is the centre of a line drawn from the anus to the tuberosity of the ischium.

The requisite division of the integuments being made, the next object is to divide the transversales perinei muscles, and to make an opening into the membranous part of the urethra, so as to be able to feel distinctly with the finger the groove and edges of the staff.

The operator has now to accomplish a very important object, and one that is for the most part sadly neglected: we allude to cutting the left side of the urethra with the knife, as far as possible along the groove of the staff towards the bladder. In doing this, the point of the scalpel should be placed in the groove of the staff, and the edge be turned to the left, while the operator's left fore-finger, applied to the back of the blade, serves to guide its course with greater steadiness and security. When this part of the operation is carefully done, very little remains to be effected by the gorget.

Were the surgeon, with too much boldness, to lay open the lower part of the urethra upward to the bladder, he would inevitably wound the rectum; "because," as an excellent writer has observed, "the motion being carried on from the urethra, it will necessarily lead to that part of the neck of the bladder that lies upon, and is contiguous to, the rectum." (Sharp in Critical Inquiry, &c. p. 212. edit. 4.) But when the urethra is divided in the manner above recommended, with the edge of the scalpel turned sideways, no risk of cutting the intestine is encountered.

The next important step is to divide the prostatic gland and neck of the bladder; for which purpose, the gorget, that disgraceful instrument, which we should like to see expelled from surgery, is designed.

Mr. Serjeant Hawkins has made his name exceedingly famous, by his having been the inventor of cutting gorgets. We have already related how the ancient surgeons sometimes employed blunt gorgets for dilating the parts, in the performance of the apparatus major. A reference to the surgical plates of this work will more readily convey an idea of what a gorget is, than any verbal description. There we have given representations of the blunt gorget, as well as of sharp gorgets, devised by Hawkins, Cline, and Abernethy. The gorget of Mr. Cline appears to us the most eligible, as it will make the freest opening into the bladder, and cut in the most desirable direction. Its edge, being quite straight, may be readily ground very sharp, and is best suited for making an even clean incision. By cutting laterally, instead of more or less obliquely upwards, a larger incision may be safely made with it than with most other gorgets, which, having their edges turned upwards, cut in a direction where the rami of the ossa ischium converge, and leave insufficient room for the easy passage of a large stone; and where also the trunk of the pudendal artery is liable to be injured, in making a wound even of moderate extent. We are firmly persuaded of the truth of Ponteau's opinion, that the stone ought always to be extracted where the arch of the pubes is widest. Cline's gorget, besides having the material advantages of making the freest opening, and cutting in the most desirable direction, also possesses the excellence of being devoid of that very useless and objectionable part, the blunt prominence on the left hand of the beak, sometimes termed the shoulder of the gorget. This should always be filed away, as it can only serve to render the introduction of the instrument more difficult.

We should like Mr. Abernethy's gorget very well, if its edge were somewhat more extensive, and had a more horizontal direction. But the first improvement would be improper without the last; since a freer cut so much upwards must endanger the pudendal artery.

Every surgeon, before undertaking lithotomy, should be careful that the beak of the gorget and the groove of the staff fit each other with precision. The embarrassment and risk of doing mischief, into which the operator would fall, could he not make the beak slide along the groove, must be plain to every understanding.

Having divided the urethra a considerable way towards the neck of the bladder, in the manner explained above, the operator is to place the beak of the gorget in the groove of the staff; and, being sure that this is accomplished, he is to rise from his chair, and take hold of the handle of the staff with his left hand, while with his right he holds the gorget with its beak carefully maintained in the groove of the staff, along which it is to glide into the bladder. But, before pushing the gorget onward, a most important thing is to be observed: this is "to bring forward the handle of the staff, so as to elevate the extremity of the instrument in the bladder; by which means, the gorget can be introduced along the groove of the staff, in the direction of the axis of the above viscus. In fact, the gorget should always be introduced nearly in a direction corresponding to a line drawn from the os coccygis to the umbilicus." By following this plan, the gorget can hardly ever wound the rectum, or imbricate itself into the cellular substance between this intestine and the bladder. It is evident, however, that there can be no safety, if the beak of the gorget should happen to slip out of the groove, which is designed to guide it.

Immediately the gorget has been introduced, the staff is to be withdrawn, and a suitable pair of forceps is to be passed, along the upper surface of the gorget, into the bladder, for the purpose of seizing and extracting the stone.

While

While the operator is passing the forceps along the gorget, the latter instrument must be kept quite motionless, lest its sharp edge should do mischief; and as soon as the forceps is in the bladder, the cutting gorget is also to be taken away.

Delineations of the forceps, used in lithotomy, will be found in the surgical plates of this work. We shall only observe, respecting this instrument, that the operator should be provided with at least three or four pairs of different sizes; and that they are commonly made of too thick and clumsy a construction, whereby they of themselves almost occupy the whole of the passage through which the stone is to be drawn.

Our description has now advanced to that point of the operation, when the staff and gorget have been withdrawn, leaving the forceps introduced. The next object is to get hold of the stone with the forceps. In doing this, the surgeon will do well to remember the judicious mode pursued by Chefelden, as detailed in our account of this gentleman's improvements. He should not unmeaningly expand the instrument, as soon as it is in the bladder; neither should he awkwardly thrust it about at random, without any determinate scheme. The most advisable method at first is not to open the forceps, but use the instrument as a kind of probe, for ascertaining the exact situation of the stone. If this body should be lodged at the lower part of the bladder, just behind the neck of this viscus, as is mostly the case, and be distinctly felt below the blades of the forceps, the operator is to open the instrument immediately over the stone, and, after depressing the blades a little, is to shut them, so as to grasp it. Great care, however, must be taken not to shut the instrument in any other than a gentle manner, as breaking the stone is an exceedingly unpleasant and troublesome occurrence. Chefelden, we are informed, used, when the stone was found soft, to interpose his finger between the blades of the forceps, in order to keep them from making too much pressure. Certainly it is far more scientific to use the forceps at first, merely to ascertain the position of the stone; for, when this is known, the operator can much more easily grasp the extraneous body in a skilful manner, than if he were to open the blades of the instrument immediately, without knowing where they ought next to be placed, or when shut. No man can doubt, that the injury which the bladder frequently suffers, from reiterated and awkward movements of the forceps, has a considerable share in giving rise to such inflammation of the viscus, as often spreads to the peritoneum and bowels, and occasions death.

When the stone is found to be so large, that it cannot be extracted without violence and laceration, the surgeon may either break the stone with a strong pair of forceps, constructed with teeth for that purpose; or by means of Mr. H. Earle's instrument; or else he may enlarge the wound with a common scalpel, or a probe-pointed bistoury, introduced under the guidance of the fore-finger of the left hand.

To the employment of the knife, in this circumstance, we have to express our decided preference. Breaking the stone in the bladder should always be avoided, if possible; as it creates such a chance of calculous fragments being left behind, and obliges the surgeon to disturb and hurt the bladder too much by the repeated introductions of the forceps. We wish it, however, to be well understood, that when the stone is excessively large, and cannot be brought through as free an opening as can be prudently made, without the employment of unwarrantable force, it is the duty of the operator to try to break it.

When this has been done, and as many of the broken pieces have been taken out as can be discovered with the

forceps, the surgeon should introduce his finger, in order to feel whether any fragments still remain behind. If they should do so, his best plan, provided they are very small, is to inject lukewarm water, with moderate force, through the wound into the bladder, for the purpose of washing them out. A sort of scoop, usually contained in every case of instruments for lithotomy, may sometimes be used in extracting pieces of broken calculi. See the surgical plates.

The operator ought always to examine a stone as soon as it is extracted; if its whole surface be rough, it is a presumptive sign that there is no other calculus present; if its outside should be smooth on one side and rough on the other, it is not improbable that there are other stones. But in every instance, the surgeon should introduce his fore-finger, in order to obtain decisive information on this point; for it would be unpardonable to put the patient to bed while another stone remains in his bladder.

Sometimes stones cannot be grasped with the forceps, unless raised by the index and middle finger of the left hand, introduced into the rectum. First Lines of the Practice of Surgery, p. 532—537. edit. ii.

Of the objections to cutting gorgets.—Mr. John Bell of Edinburgh, in his Principles of Surgery, vol. ii. has freely delivered his sentiments on the dangers and disadvantages of the cutting gorget, and as we think there is much reason and truth in what he has said, his observations appear to us well worthy of the most serious consideration. They tend to shew that there is no method of performing lithotomy so excellent as that with only a staff and a scalpel, and that if surgeons would take the trouble to qualify themselves for this last mode of operating, a thing by no means difficult, all cutting gorgets might be for ever laid aside, to the great benefit of mankind, and the real improvement of surgery. Mr. John Bell reminds us that "*the gorget slips!*" and all the surgeons of Europe confess it! it slips in the hands of the most skilful surgeons, and no one can be responsible for the consequences of a thrust so desperate, and requiring so much force. It slips so frequently, and is avowedly so little under the controul of the operator, that no man ventures to blame his brother for a misfortune which may happen in his own hand. So imperfect is the instrument, and so dangerous this plunge, that to prevent the gorget being driven through the fundus of the bladder, is a point of so much importance as to occupy, to this day, the genius of inventors, who have thought to guard the edge by a double, or hipped gorget! and so far is the incision, after it is safely made, from being adequate to the extraction of the stone, that the size and form of the gorget, and especially the expansion of its blade, and the broadness of its cutting edge, varies every day. The instrument was once conical, but is now cylindrical; it was once narrow, but is now broad; it was once double, with the beak in the centre: it is now single, with the beak on one side; when first sharpened by Mr. Cusar Hawkins, it was round, because it had been immediately before a mere dilator; it is now flat, and entirely resembles a knife.

"It is not without reluctance, (proceeds Mr. John Bell,) that I rank this among the inventions, where mechanism is substituted for skill. If this form of instrument were found safe in practice, I should be as little apt as any man to be infected by speculative fears; but it is a murderous weapon! When the dash is made with the gorget, either it is at once successful, or, if wrong, is irretrievably so; for though in operating with the knife, you can make a second incision, in operating with the gorget, if you fail in the first, you can make no second plunge. The best operators in this country, among whom I have no doubt I may reckon Mr.

Earle, acknowledge the dangers of this operation in the fullest and most unqualified terms: 'I have more than once known a gorget, though passed in the right direction, pushed on so far, and with such violence, as to go through the opposite side of the bladder.' (Earle on the Stone, p. 33.) I have myself, (says Mr. John Bell,) seen it driven, God knows where, deep out of sight, up to the hilt, without one drop of urine issuing, without the operator ever reaching the stone. Observe but the force with which the operator drives in the gorget; mark the struggle with which he disengages the beak of the gorget from the groove of the staff; hearken to the audible clack with which the beak of the gorget shoots off from the groove of the staff; and if this moment of violence do not conspire with the outcries of the unhappy patient to persuade you of the dangers of this operation, you can have but little pretension to either feeling or knowledge. Such is the rude violence with which the gorget is driven inwards, that Bromfield, even when operating with a blunt gorget, a mere dilator burst through the bladder and peritoneum; his gorget went almost beyond his reach into the abdomen, while the bowels of the boy fell down into his hands.

"But, (says Mr. J. Bell,) there is one paramount objection, independent of the many dangers which attend this push of the gorget; 'the instrument, guide it how you will, makes an incision inadequate to the easy extraction of the stone.' I have often compared the incisions I have made with the knife and with the gorget, upon the dead body. I have observed also, in the time of operating, how difficultly the opening of the prostate admits even the forceps, how impossible that such an imperfect incision should easily allow the extraction of the stone. In all cases of particular difficulty, where, using the privilege of an assistant, I have introduced my finger, I have felt distinctly the fracture of the gland, the greater part of it being left entire. The incision in the gland often admits the forceps so difficultly, that I am well assured the gland itself has sometimes, by the mere pushing of the forceps against this firm and narrow opening, been entirely separated from the urethra! and after the forceps are pushed successfully through this narrow opening, and the stone caught betwixt their blades, all that remains of the gland is inevitably lacerated with much danger and pain. But I would more willingly quote any authority than that of my own dissections, or experience. Camper, who has studied this subject, says "*incredibile est, quam parva plaga ab omnibus etiam dextrinis insigatur; nunquam forcipem robustam exciperet nisi dilataretur. Hawkenius solo conductore, ejus margo dexter in aciem assurgit, idem præstat; omnes plagam dilatant, ut calculum extrahant; dilaceretur igitur semper vesica ossium et prolata.*" P. 14.

"But, (continues Mr. J. Bell,) higher and better authority remains behind. Dease was, if I judged rightly of his talents, a stern and rude surgeon, but perfect in all the theory and practice of his art; he was not very explicit in his communications with me, but from the manner and the movement of his hand, in demonstrating to me, rather than from what he said, I conclude that he cut after the manner of Raw, making the incision with the right hand, while he held the staff with his left. "In all the trials, (says Dease,) that I have made with the gorget on the dead subject, I have never found the opening into the bladder sufficiently large for the extraction of a stone of a middling size, without a considerable laceration of the parts. I have frequently taken the largest sized gorget, and could not find, that in the adult subject, I ever entirely divided the prostate gland, if it was any way large; and in the operations that were

performed here on the living subject, the extraction was painfully tedious, and effected with great difficulty, and in some cases not at all." See John Bell's Principles of Surgery, vol. ii. p. 173—176.

We coincide entirely with Mr. J. Bell respecting the dangers and disadvantages of the cutting gorget, and could adduce several cases where operators have committed, with this instrument, the most fatal blunders. It is also our conviction that many deaths, after the operation, are owing to the consequences of the opening being, in general, too small, so that the forceps are sometimes introduced and withdrawn twenty times before the stone can be extracted, and when this is accomplished, it is with immense violence and laceration. The most perfect lithotomy appears to us only to admit of being done with a scalpel and a staff; and the more we reflect on the subject, the more we are convinced of the excellency of Cheselden's practice.

Of some particular methods and instruments.—The subject of lithotomy is almost an endless one, and many sheets of this work would be taken up by a full explanation of all the various methods. Such readers as wish for so minute and long an account, are particularly referred to Sabatier's Médecine Opératoire, tom. ii. and to Mr. John Bell's Principles of Surgery, vol. ii. May it be sufficient in this publication to make mention of some of the most interesting of these numerous proposals, in doing which, we shall avail ourselves of some remarks contained in an instructive paper inserted in the Edinb. Med. and Surg. Journal, vol. iv. by Mr. Allan Burns, lecturer on anatomy and surgery, Glasgow.

Frère Côme's method with the lithotome cachée.—John de Saint Côme, of the order of Feuillans at Paris, was the inventor of a knife, concealed in a sheath, out of which the blade springs, on touching a kind of lever at the side of the handle of the instrument. The distance to which the blade starts out, may be regulated by the surgeon before the operation, according to the extent of the wound that he may be desirous of making. The patient being placed as in the lateral operation with the gorget, and a staff introduced, the surgeon, with a scalpel, is to begin the first incision on the left side of the raphe of the perineum, about ten lines in front of the anus. This cut is to be continued obliquely downwards and outwards, as far as the centre of a line extending from the anus to the inside of the tuberosity of the ischium. The external incision is to divide the integuments of the left side of the perineum, the accelerator urinae, the erector penis, the transversus, and the front fibres of the levator ani. These parts having been cut, the index finger of the left hand is to be introduced into the left angle of the wound, with its radial side downwards. The right edge of the groove of the staff is to be placed between the nail and skin at the end of the finger. The point of the scalpel is to be conducted into the groove of the staff along the nail, which faces the left. The index finger is now to be turned, in order that its extremity may press upon the point of the knife, which all along is to be held with the right hand, like a writing pen. The urethra is thus to be slit open to the extent of five or six lines. The nail of the left index finger is next to be placed in the groove of the staff, and is to serve as a means of guiding the end of the lithotome into that groove. As soon as the latter object has been accomplished, the finger is to be withdrawn; the surgeon, with his left hand, is to take hold of the handle of the staff; and by one simultaneous movement, he is to raise the two ends of the instruments together towards the symphysis of the pubes, by which means the lithotome will be easily conducted into the bladder. The entrance of the lithotome into the cavity of this viscus will be indicated by cessation of resistance, and the freer issue of

the urine. The end of this instrument, being in contact with the cul-de-sac extremity of the groove of the staff, must be disengaged by a slight lateral movement. The staff is now to be withdrawn. The operator, with his left thumb and index finger, is then to take hold of the lithotome, about the place where its sheath and handle meet. He is to conduct the instrument under the symphysis pubis, turning the edge downwards and towards the left side of the perineum, in the direction of the external incision. On pressing a lever, the blade of the lithotome quits the sheath, when the instrument is to be drawn out horizontally. Thus the prostate and neck of the bladder are divided. The forceps are then introduced, and the operation finished in the ordinary way.

The lithotome *caché* of Frère Côme is yet employed at the Westminster Hospital, and has been lately tried by Mr. A. Cooper. It is still more commonly used in France. The objections, however, which have thrown discredit upon it, are, that from its mechanism, and the structure of the parts about the pelvis, it is likely to wound the pudendal artery; that the bladder, if collapsed, may be injured in more than one place; and that if the knife be directed downwards too obliquely, the rectum is apt to be cut.

Apparatus altus as modified by Frère Côme and Deschamps.—Absolute necessity led to the introduction of the high operation by Franco in 1561; and the same cause occasioned its revival, in 1658, by Frère Côme. The operation, as performed by Franco, was defective: a high incision was alone made into the bladder; this viscus was opened above the pubes, below the point where the peritoneum is reflected over the abdominal muscles: the stone was easily extracted; but as there was no dependent opening from the bladder, the urine was apt to insinuate itself into the cellular membrane about the pubes, to irritate and inflame the parts, and to produce either gangrene or suppuration, and the formation of sinuses. These disadvantages led to the disuse of the apparatus altus, till revived and new-modelled by Frère Côme, who proposed to open the bladder in perineo, and then, through an opening made just above the pubes, he introduced a scalpel with a button point, with which he slit up, for an inch or two, the linea alba; the knob on the end of the knife pushing aside the peritoneum. After this, he introduced, by the aperture in perineo, a staff, with which he made the bladder project through the opening between the recti muscles. This done, he cut into the front of the bladder, and either with his finger and thumb, or with a pair of forceps, he took out the stone. In this way he extracted from the bladder a calculus, that weighed twenty-four ounces. On this method Mr. Allan Burns remarks, that it might with propriety be adopted, were it not for the danger attendant on the double incision into the bladder, and the protraction of the operation by the dissection about the perineum. Indeed, as modified by Deschamps, who, in place of the puncture in perineo, perforates the bladder from the rectum, it has met with the approbation of Mr. Thomson of Edinburgh, who considers this, on particular occasions, to be the most advisable method of operating. Mr. A. Burns thinks, however, that if the bladder be thickened and indurated, it will be impossible to raise it with the cannula above the pubes. Hence, this plan is only admissible, when we have reason to suppose that the stone is too large to be removed by the perineum, and that the bladder is healthy. Here the puncture from the rectum is simple, attended with no increase of the danger, allows the bladder to be elevated with the cannula, and secures a dependent outlet for the urine. Thus we avoid the necessity of any discharge by the wound above the pubes; we run no risk of the urine insinuating itself into the cellular

membrane, no inflammation is excited, no sinuses are formed; consequently, the person ought speedily to recover. *Edin. Med. and Surg. Journ.* vol. iv.

Invention of staffs, from which the gorget cannot slip.—The danger of the gorget slipping out of the groove of the staff has been already sufficiently commented on. Le Cat, in 1747, and Sir C. Blicke, more lately, endeavoured to obviate such risk, by proposing to use staffs with contracted grooves. The beak of the gorget is locked and fixed in the groove of the staff, till it has arrived near the end of this latter instrument, where the groove has a wider construction. Notwithstanding the plausibility of this contrivance, there are reasons which have deterred practitioners from employing it. Few surgeons have been inclined to trust to the fort of gorget that must be used; the point of contact of the beak and body of the instrument being necessarily so small, that on the slightest deviation from the direct line, in pushing such a gorget into the bladder, the beak breaks off, the gorget separates from the staff, and the seminal vessels and rectum are exposed to injury. Besides, another objection is, that the gorget is frequently slipped in the groove of this kind of staff, at the most critical period of the operation.

Methods of Le Dran, Deale, and Muir.—Le Dran, in 1741, published his *Operations of Surgery*. In this work, the author describes an operation, the introduction of which has been claimed by several since his time. The principle of the plan alluded to was to reduce the male into the state of the female urethra.

The late Mr. Deale of Dublin, and Mr. Muir of Glasgow, reflecting that the great cause of the gorget slipping from the staff depends upon the former being pushed along a curved surface; and observing, that such an accident seldom or never happens on females; have proposed, like Le Dran, to make the male urethra resemble the female. To accomplish this, they introduce, as usual, a curved grooved staff into the urethra, and make the common incision in perineo: they then open the membranous part of the urethra; but, instead of now introducing the gorget, they conduct along the groove a female staff, and immediately withdraw the curved one. With the left hand they take hold of the handle of the straight staff, and with the right introduce the gorget.

Double staffs.—It is said that some operators have experienced considerable difficulty in finding the groove of the staff in the perineum. To facilitate this business is the principal design of the double staff, an instrument which is now quite laid aside. In fact, the trouble of cutting into the staff is not great enough, to render any invention of this sort at all important.

The first instrument for this purpose we find described by Deschamps, as the invention of Jarda, a surgeon at Montpellier. According to Mr. A. Burns, it resembles Earle's double staff; but is more complex. It consists of a curved staff, intended to be introduced along the urethra into the bladder, and having connected to its handle, by means of a hinge, another staff, shorter than the former, and sharp at its end. When Jarda had applied the short staff to the perineum, he pushed its point through the skin, behind the bulb of the urethra, into the groove of the long staff already passed through this canal. This supplementary staff, in both Jarda and Earle's instrument, is intended to conduct the knife into the groove of the staff. But Jarda aimed at more: he wished to secure the rectum from injury, by introducing into the anus a limb of the instrument, which he expected would push the gut aside. By machinery, he also contrived

contrived to support the scrotum. Edinb. Med. and Surg. Journal, vol. ix.

Mr. Allan Burns' method.—The plan introduced by Cheselden, and revived by Mr. John Bell, is that which Mr. A. Burns would affirm is the basis of the operation; but with the he proposes to blend Mr. Dease's mode.

"For more than twelve months," says Mr. Burns, "I have been in the habit of shewing such an operation, which is as simple in its performance as the one in general use, is attended with less danger to the patient, permits of an incision varying in size according to the wish of the operator, and completely prevents injury of the rectum or pudic artery. To perform this operation, I introduce into the urethra a common curved staff, then make the usual incision into the perineum, divide fully and freely the levator ani, so as to expose the whole extent of the membranous part of the urethra, the complete extent of the prostate gland, and a portion of the side of the neck of the bladder. When this part of the operation is finished, I open the membranous part of the urethra, and introduce, through the slit, a straight or female staff, with which I feel the stone, and then withdraw the curved staff. Next I feel beyond the prostate for the instrument, and then perforate the coats of the bladder with a curved knife, the point of which is to be inserted in the groove of the staff. This done, I grasp the handle of the staff firmly in my left hand, and with the right lay hold of the handle of the knife. Having ascertained that the two instruments are in fair contact, I rest the one hand upon the other, pressing them together, and then, by a steady extraction, I pull out the knife and staff together, which is preferable to drawing the knife along the staff: it prevents the risk of the one slipping from the other; it guards the bulb of the urethra, and every other part from injury; for, between them and the cutting instrument the staff is interposed. In the introduction of the knife, however, some caution is necessary, and a clear knowledge of the relative situation of the parts in the pelvis is requisite; but this information is equally necessary in operating with the gorget. When introducing the knife, the side of the blade must be laid flat along the fore-finger of the right hand, which is to project a little beyond the point. In this state, the finger and knife are to be entered into the wound, opposite the tubercle; but, in proportion as they pass along, they are to be inclined forward, till at last, with the point of the finger, the staff be felt through the coats of the bladder, a little beyond the prostate, and rather higher than the orifice of the urethra. Here the knife is, with the finger, to be pushed through the bladder; and when the point is fairly fixed in the groove of the staff, the operation is to be finished by the steady extraction of both instruments. In operating with the gorget, it is necessary that the bladder be more or less distended; a circumstance, in some cases, with difficulty accomplished, from the irritability of this viscus. In operating with the knife, the parts can be as safely cut when the bladder is empty as when full; indeed, perhaps, with greater safety; for, when not dilated, the shoulder of this viscus can more easily be pushed in, so as to permit the finger to reach the staff. Some have imagined, that the introduction of the point of the knife into the cavity of the bladder must be dangerous, inasmuch as we are liable to wound the sides, in searching for the groove of the staff. This objection is the result of an inaccurate knowledge of the state of the parts: for, in fact, we never grope in the bladder with the point of the knife; but, with the finger, push in the side of this viscus into close contact with the staff, into the groove of which the knife enters, as soon as it has passed through the coats of the bladder. Others again have

objected to this mode of operating, on the idea of its being more tedious in performance than with the gorget. This is also founded on a mistaken notion. True it is, indeed, that were a surgeon, who has been much in the habit of operating with the gorget, to exchange it for the knife, he would undoubtedly be longer of performing the operation in the latter way: but the same does not hold good respecting those who have never before operated in either mode. From all that I have seen, I would say, that the one operation may be as expeditiously performed as the other: but even admitting that the operation with the knife uniformly required a little longer time, still I think that, if safer, it ought to have the preference." Edinb. Med. and Surg. Journal, vol. ix. p. 65—67.

The instruments, used by Mr. Burns, are represented in the surgical plates of this Cyclopædia.

We shall merely say, that we think that the above plan of operating is much better than the common mode of cutting for the stone with a gorget; nor can it be found fault with on the ground of difficulty. Notwithstanding its merit, however, few seem disposed to give it a fair trial; but continue the employment of that dangerous and insufficient instrument, the gorget, as much as ever.

Of lithotomy, as performed each common scalpel, and some other kinds of knives.—The fact of Cheselden having cut for the stone sixty-two patients in succession, of whom all recovered, excepting two, is an invincible argument in favour of his method of operating. It may be expected, that we should describe the mode of executing the operation with a scalpel; but after the full account which we have delivered of Cheselden's plan, this duty in reality becomes superfluous. The few judicious surgeons of the present day, who have given the preference to the common scalpel, have all operated either after Cheselden's second or third manner. The last has been chosen by Mr. John Bell, and is that which was crowned with such matchless success in the practice of its inventor. The lateral operation, as thus executed by Cheselden, was truly once the pride of English surgery, to use an expression of that able professor, Dr. J. Thomson of Edinburgh. Other operators have preferred operating after the manner of Cheselden's second method, viz. by cutting from the urethra towards the bladder.

Mr. Charles Bell has proposed the employment of a staff, the groove of which, towards the extremity of the instrument, runs along its right side or edge. Operative Surgery, vol. i.

It would be a tedious and endless business to describe all the various knives which different surgeons have suggested for lithotomy. The late Mr. Hunter had a particular one. Mr. Astley Cooper has used a knife, much resembling a common dissecting scalpel, but having a beak, by which it may be guided along the groove of the staff. We hear that this distinguished surgeon is now trying Frère Côme's lithotome caché. A much approved knife for lithotomy was some time since invented by Mr. Gibson, and another by Mr. T. Bizard. Engravings of all these will be found in the surgical plates of this work. Our objection to these beaked knives is, that they are in reality gorgets.

Of lithotomy in Women.—Women suffer much less from the stone than men, and far less frequently stand in need of this operation. It is not, however, that their urine will not so easily produce the concretions, which are termed urinary calculi. The reason is altogether owing to the shortness, largeness, and very dilatible nature of the female urethra; circumstances, which in general render the expulsion of the stone with the urine almost a matter of certainty. The records of surgery present us with numerous

instances,

instances, where calculi of vast size have been spontaneously voided through the meatus urinarius, either suddenly without pain, or after more or less time and suffering. Heister mentions several well authenticated examples of this kind. Middleton has also related a case, where a stone, weighing four ounces, was expelled in a fit of coughing, after lodging in the passage a week. Collet speaks of another instance, where a stone, about as large as a goose's egg, after lying in the meatus urinarius seven or eight days, and causing a retention of urine, was voided in a paroxysm of pain. A remarkable case is related by Dr. Molinieux in the early part of the *Philosophical Transactions*: a woman voided a stone, "the circumference of which measured, the longest way, $7\frac{1}{4}$ inches, and round about, where it was thickest, $5\frac{3}{4}$ inches, its weight near $2\frac{1}{2}$ ounces troy."

Sometimes, after the passage of large calculi, the patient has been afflicted with an incontinence of urine; but this grievance, in general, lasts only a short time.

The naturally large size, and dilatable nature of the female urethra, have suggested the plan of endeavouring to expand this passage by various means, so that a stone in the bladder may be taken out with a pair of forceps, without using any cutting instrument at all. This method was proposed by Douglas nearly a century ago, who not only recommended sponge for the purpose, but also dried gentian root, as being more gradual in its expansion, and better adapted to the object.

Mr. Bromfield has given the case of a young girl, where he effected the dilatation by introducing into the meatus urinarius the appendicula cæci of a small animal in a collapsed state, and then filling it with warm water, by means of a syringe. The piece of gut, thus distended, was drawn out, in proportion as the cervix vesicæ opened, and in a few hours the dilatation was so far accomplished, that the calculus had room to pass out. See *Chirurgical Obs. and Cases*, vol. ii. p. 276.

Mr. Thomas lately met with a case, where, after dilating the meatus urinarius with sponge tent, he succeeded in extracting an ear-picker, which lay across the neck of the bladder. The passage was so much enlarged, that the left fore-finger was most easily introduced, and, (says this gentleman,) "I believe, had the case required it, both thumb and finger would have passed into the bladder without the smallest difficulty."

After adverting to this case, and other facts proving the ease with which the female urethra can be dilated, Mr. Thomas remarks; "If these relations can be credited, and there is no reason why they should not, I can hardly conceive any case, in a young and healthy female subject, and where the bladder is free from disease, where a very large stone may not be extracted, without the use of any other instrument than the forceps, the urethra having first been sufficiently dilated by means of the sponge tents. For this purpose, the blades of the forceps need not be so thick and strong as those commonly employed." See *Medico-Chirurgical Transactions*, vol. i. p. 123—129.

Some surgeons have extracted stones from the female bladder as follows: the patient being placed in the position commonly adopted in the lateral operation, a straight staff, with a blunt end, is introduced into the bladder through the meatus urinarius. The surgeon then passes along the groove of the instrument the beak of a blunt gorget, which, becoming wider towards the handle, effects a part of the necessary dilatation. The staff being withdrawn, and the handle of the gorget taken hold of with the left hand, the right fore-finger, with the nail turned downwards, is now introduced slowly along the concavity of the instrument.

When the urethra and neck of the bladder have thus been sufficiently dilated, the finger is withdrawn, and a small pair of forceps passed into the bladder. The gorget is now removed, and the stone taken hold of and extracted. See *Sabatier's Med. Opérateur*, tom. ii. p. 103.

Notwithstanding these favourable accounts of the practice of dilating the female urethra, for the purpose of removing calculi from the bladder, the generality of surgeons prefer an incision. It is certain, that some patients have found the method insufferably painful and tedious. But the strongest objection to the practice has arisen from the incontinence of urine, which occasionally follows any great distension of the urethra and neck of the bladder. Mr. Thomas believes, however, that this unpleasant symptom is quite as often a consequence of the operation of lithotomy, as now usually performed. *Medico-Chirurgical Trans.* vol. i. p. 127.

Lithotomy on females is much more easy of execution, and less dangerous, than the same operation on the male sex. It may be done in various ways; but the surgeons of the present time constantly follow the mode of making the requisite opening by dividing the urethra and neck of the bladder. A straight staff, or director, is introduced through the meatus urinarius; the groove is turned obliquely downwards and outwards, in a direction parallel to the ramus of the left os pubis; and a gorget or knife, is thus conducted into the bladder, and makes the necessary incision. Some operators prefer the lithotome caché, which, after being introduced, is opened as far as is deemed proper, and then drawn out with its edge turned obliquely outwards and downwards.

The French surgeons Louis and Flurant were the inventors of particular bistouries for dividing both sides of the female urethra at once; the instrument of the former effected this purpose, in passing from without inwards; that of the latter in passing from within outwards. Flurant's bistoury bears some resemblance in principle to Frère Côme's lithotome caché, or to the cutting forceps with which Franco used to divide the neck of the bladder. The reason assigned for these bistouries is, that they will serve to make a freer opening for the passage of large stones, than can be safely made by cutting only in one direction. At present, however, they are never used. Were the stone known to be very large, Sabatier seems to prefer the apparatus altus.

A case may present itself, where the posterior part of the bladder, drawn downwards by the weight of the stone, might displace a portion of the vagina, and make it protrude at the vulva, in the form of a swelling. Here, there would be no doubt of the propriety of cutting into the tumour, and taking out the foreign body contained in it. Roussel performed such an operation, and Fabricius Hildanus, in a case where the stone had partly made its way into the vagina by ulceration, enlarged the opening, and successfully extracted the extraneous body.

M. Méry once proposed the method of making an opening into the posterior part of the bladder, through the vagina, after introducing a common curved staff; but the apprehension of urinary fistula made him abandon the project.

The existence of extraordinary circumstances may always render a deviation from the common modes of operating not only justifiable, but absolutely necessary. Thus, Tolet met with a case, where a woman had a prolapsus of the uterus, with which the bladder was also displaced. In the latter viscous, several calculi were perceived. An incision was made into it, and the stones extracted, after which opera-

tion the displaced parts were reduced, and a cure speedily ensued. Sabatier's *Med. Opératoire*, tom. ii. p. 107.

Treatment after the operation.—Whatever method of performing lithotomy has been selected, the great danger afterwards is the access of inflammation of the bladder, peritoneum, and parts within the pelvis and abdomen in general. This alarming disorder is the common cause of the numerous deaths which follow the ordinary modes of operating. The best method of preventing it is, as we have repeatedly explained, to make a free and ample opening for the passage of the stone, and to avoid all manual roughness and violence in the operation. But supposing tenderness and tension to have begun about the hypogastric region, attended with a small frequent pulse, pain over the abdomen, sickness, thirst, &c. not a moment must be lost; as nothing will save the patient but the prompt and decisive employment of antiphlogistic measures.

This much dreaded and fatal disorder is particularly to be expected, when the patient is of a full sanguineous habit, when the operation has been long and difficult, when much violence has been used in drawing out the stone, or when the bladder has been bruised by the reiterated introduction of the forceps, whether for the purpose of taking out one calculus, or several, or the fragment of one that has been broken. The perilous inflammation within the abdomen, however, may come on, even when the operation has been executed in the most expert and easy manner. The most effectual means against the complaint, are copious venesection, and placing the patient for some hours in a warm bath. These measures should be taken immediately when the complaint is indicated by the least pain and tension about the lower part of the abdomen. But, besides bleeding and the warm bath, an endeavour should be made to procure stools by giving the oleum ricini. When the patient is removed from the bath, a blister, or else leeches and fomentations, may be applied to the hypogastric region.

Were we to judge from the observations derived from the practice which it has fallen to our lot to see, we should suppose, that the danger of hemorrhage after lithotomy has been generally exaggerated; for out of a vast many operations which we have been spectators of, there has not been one death from loss of blood. But as wounding the pudendal artery may happen more frequently with some operators, whom we have had no opportunities of noticing, we are inclined to believe, not that the danger is unjustly magnified, but that the particular surgeons whom we have seen operate have generally eluded it.

In order to stop the bleeding from the trunk of the pudendal or pudic artery, authors advise us to introduce into the wound a cannula wrapt round with lint, for the purpose of making pressure on the wounded part of the vessel. Boyer is said to have suppressed the hemorrhage in several instances, by introducing deeply into the wound a large doasil, round which is tied a ligature, the ends of which, being separated, are to be forcibly tied over a second doasil. The constriction tends to draw outwards the first doasil, at the same time that it propels inwards that which is more external. Richerand, *Nosographie Chir.* t. iii. p. 533, edit. 2.

Secondary hemorrhages sometimes occur in old debilitated subjects several days after the operation, and may prove fatal. They require the same treatment as the foregoing bleeding, though, notwithstanding the most skilful compression, the blood will often continue to ooze from day to day, till the patient falls a victim.

Were a patient to bleed profusely from a wound of the pudendal artery, the vessel might be taken up and tied by a

good surgeon, which would be a much safer method than compression. It seems, that in one example, Mr. Abernethy tied the trunk of this artery, where it passes along the inner surface of the tuberosity and ramus of the ischium. See *Medical and Physical Journal*, vol. ix. p. 393.

The dressings after the lateral operation are superficial, and kept on with a T bandage. As separating the thighs pulls asunder the edges of the wound in the perineum, it is also customary to confine them together, when the patient is put to bed by means of a garter applied just above the knees.

LITHOXOS. See COLAFICE.

LITHOXYLON, in *Minerology*, *Woodstone*, *Holzstein* of Werner, a species of siliceous genus in the arrangement of Kirwan. Its colour is generally blackish, or bluish-grey; the former frequently passing into the greyish-black, and the latter into the greyish white; and this from the light reddish-grey, into the blood or cochineal red. Seldom ochre yellow or mountain green; sometimes reddish or yellowish-brown. These colours commonly appear together in spots, blotches, or stripes, in the same specimen. It always manifests its pristine state, either by its branchy form, or its knots or roots. Its surface, like that of the wood from which it originates, is sometimes rough, sometimes uneven, sometimes coarsely streaked in the direction of its length. Its internal lustre, 1; its transparency, 1.2. Its fracture conchoidal; sometimes imperfectly, or approaching to the fine splintery, sometimes flaty; and generally, by its interlaced fibrous structure, discovers its origin. Its fragments 3. Often splintery; its hardness, 10; the specific gravity of different specimens extended, upon Mr. Kirwan's trials, from 2.045 to 2.675. It is commonly, but not always, the substance of petrified wood. It often withers by exposure to the atmosphere. Its transitions are into quartz, calcedony, and, as some say, into pitch stone or opal. Kirwan's *El. of Min.* vol. i.

LITHOXYLUM, in *Botany*, a term used by Linnæus to express a heterogeneous substance on marine productions, which has fructifications in impressed points. See GORGONIA.

LITHOZUGIA, in *Natural History*, the name of a genus of fossils, of the class of the icrupi, composed of a crystalline matter a little debased, and containing within them various extraneous bodies, as pebbles, &c.

Dr Woodward has ranked this genus among the pebbles, because of the pebbles they contain; which is by no means a sufficient reason for confounding two such different fossils: the lithozugia approaching to the nature of flint.

Mercatus and other naturalists have called the lithozugia, *aculati lapides*; and among English lapidaries they are known by the name of *pebbly-stones*; which see.

LITHUANIA, in *Geography*, a country of Europe of considerable extent, anciently a separate duchy, and afterwards united to Poland. Its capital was Vilna or Wilna, but its principal town was Grodno. When it was governed by its own sovereigns under the title of Great Dukes, a rivalry subsisted between this duchy and the contiguous states of Russia and Poland, which was the occasion of frequent contests. At so early a period as the 11th century, the Lithuanians, descended from the ancient stock of the *Slavonians* (see the article LETTIS,) are enumerated by Nestor in his chronicle, under the appellation Litva, among the nations tributary to the Russian monarchy; nor could they find means to render themselves an independent nation, till the time when dangerous intestine divisions sprang up in Russia, under the successors of Vladimir the Great, who died in the year 1015. At this time they were freed from the

the Russian supremacy, enlarged their borders at the expense of their former masters, and at length grew to be formidable to all their neighbours. In the year 1386, the great duke Ladislaus Jaghelson, or Yaghello, having espoused the Polish queen Hadevige, and embraced the Christian religion, was raised to the Polish throne, and reigned over both Poland and Lithuania. In consequence of the union of the two countries, the conquered Russian provinces devolved to this united kingdom. Ladislaus manifested the reality of his conversion, by endeavouring to propagate the Christian doctrines among his idolatrous subjects in Lithuania; accordingly he cut down the hollowed groves, destroyed the oracular shrine, extinguished the sacred fire, and slew the serpents that were worshipped as gods by his superstitious subjects. A belief universally prevailed among the people, that whoever profanely attempted to destroy these objects of their worship, would be struck with instantaneous death; but the fallacy of this tradition was evinced by the impunity of those who were concerned in the supposed sacrilege. The Lithuanians flocked in such crowds to be converted, that the priests could only confer separate baptism on persons of distinction; but distributed the multitude in ranks, and sprinkling them with water, gave one Christian name to each rank without distinction of sex. Ladislaus, having thus introduced the Christian religion into Lithuania, nominated his brother Casimir Skargello governor of the duchy, and returned to Poland; but a civil war being excited by the ambition of Alexander, surnamed Vitoldus, and by the discontents of the people, still attached to their Pagan rites, Lithuania was for some time a scene of tumult and hostility. At length, by a compromise in 1392, Vitoldus was appointed great duke, and Ladislaus contented himself with a nominal sovereignty. In 1401 the nobles of Lithuania assembled at Vilna, and entered into an offensive and defensive alliance with the king and republic of Poland. In 1413, it was stipulated in a diet of Poles and Lithuanians, held in the town of Hrodlo, that, upon the demise of Vitoldus, the Lithuanians should acknowledge no other great duke but the person who should be appointed by the king, and with the agreement of the two nations; that if Ladislaus died without issue, the Poles should elect no king without the consent of Vitoldus and the Lithuanians, and that a diet, composed of representatives from both nations, should meet at Lublin or Panzow. From the demise of Vitoldus, who expired in 1430, in the 80th year of his age, the great dukes were sometimes, in conformity to this compact, nominated by the kings of Poland, at other times in violation of it by the Lithuanians. At length Sigismund I. fortunately united in his person the two sovereignties, and was succeeded in both by his son Sigismund Augustus. The connection between the two nations was, however, more an alliance than an union; but Sigismund Augustus having no children, and being the only surviving male heir of the Jaghelson family, planned the union of Poland and Lithuania, lest upon his decease the two nations should again be governed by different princes. For this purpose a general diet was held at Lublin in 1569; and upon the ratification of the union, Sigismund Augustus renounced all hereditary right to Lithuania. From this time the same person was uniformly elected king of Poland and great duke of Lithuania, and the two nations were incorporated into one republic. Since this period, Lithuania has shared the fortunes of Poland; and with the gradual extinction of it, has likewise fallen a prey to her stronger and more powerful neighbours. At the partition of the year 1773, Lithuania furnished the whole share which Russia at that time obtained, and out of which the present vice-royalties of Mohilef and Polotzk are formed.

In the subsequent partition of the year 1793, this grand duchy again lost 1731 square miles, and 850,000 souls, which now belong to the vice-royalty of Minsk; and in the final partition of the year 1795, the last remains of Lithuania also fell to the Russian empire, of which at present the vice-royalties of Vilna and Slonimsk are formed. These provinces of the Russian empire are therefore those in which Lithuanians reside; but the number of people of which this nation consists, can hardly be given with any degree of accuracy, as they are every where mingled with Russians and Poles.

Lithuania was formerly a very woody country, but the greatest part of it was uncultivated. However, under the tranquil reigns of Sigismund I. and his successors, the woods were cleared in a great degree, and agriculture was encouraged. Potatoes and wood-ashes are made here in great abundance, and the country produces much corn. It also yields a great quantity of honey, from which are made the liquors called Lippitz, Mallinbeck, and Mead. Its meadows and pastures are fertile, and supply food for numerous flocks and herds. The wool is very fine. The lakes abound with fish; and the forests are the haunts of bears, wolves, wild boars, buffaloes, deer, and large flights of woodcocks. All sorts of provisions are cheap, but cash is so scarce, that 10 *per cent.* is the common interest for money. The common people are generally vassals, and the nobility are numerous, but poor; some of the principal of them excepted, who possess princely revenues, occupy the chief posts in the country, and live in great pomp and splendour.

LITHUANIA, *Little, or Prussian*, a province of Prussia, about 100 miles in length and half as much in breadth. This country was anciently over-run with thickets and woods; and in the year 1710, it was almost depopulated by a pestilence. In 1720, Frederick William, at a great expense, induced many Switzers, French Protestants, Palatines and Franconians to settle here, and in 1732, 350,000 dollars were distributed among a fresh colony of 12,500 Saltzburghers. These emigrants changed the face of the almost desolated country, and its fertility appeared in the multitude and variety of its productions; such as corn, horned cattle, numerous flocks of sheep, excellent horses, butter, cheese, &c. It afforded likewise plenty of fish and game. Several manufactures are also established here, for coarse and fine cloth, leather, &c. The ancient inhabitants of this country have a language peculiar to themselves, into which the bible and some religious books have been lately translated. The colonists of this country are engaged in various employments, to which their disposition and habits incline them; and with respect to religion, the Switzers, French, and Franconians, are Calvinists; so that there are 10 German and French reformed parishes, as they are denominated, in Little Lithuania. The rest are Lutherans, intermixed with a few Papists. The principal towns are Memel, Tilt, Ragnit, and Ilberburg.

LIPPITZ, or LIPPITZ, a town, or rather village, of America, in Lancaster county, Pennsylvania; situated in the township of Warwick, containing about 50 houses, and an elegant church with a steeple and bell, settled in 1757, and inhabited by the United Brethren, amounting, in 1787, to upwards of 300; eight miles N. of Lancaster.

LITMUS, or LACMUS, in the *Arts*, is a blue pigment, or violet red paste, formed from *Lithm*, which see. It is brought from Holland at a cheap rate; but may be prepared by adding quick-lime, and purified urine, or spirit of urine distilled from lime, to the archil previously bruised by grinding. The mixture, having cooled, and the fluid suffered to evaporate, becomes a mass of the consistence of a paste.

a paste, which is laid on boards to dry, in square lumps. The following is given as the exact process for preparing it. (Nicholson's Journal, 4to. vol. ii.) The lichen is first dried, cleansed, and pulverised, in a mill like the oil-mill. The powder is then thrown into a trough, with one-half its weight of pearl-ash, and moistened with a little human urine, and allowed to ferment. This fermentation is kept up for some time, by successive additions of urine, till the colour of the materials changes first to red, then to blue. In this state it is mixed with a third its weight of very good potash, and spread upon deep wooden trays till dry. A quantity of chalk is added at last, apparently for the mere purpose of increasing the weight. It is only used in miniature paintings, and cannot be well depended on, because the least approach of acid changes it instantly from blue to red. This property renders the colour a valuable tint to the chemist, in detecting the presence of uncombined acids. But when redened by an acid, the blue is restored by an alkali: so that litmus may thus become a test both of acid and of alkali. The best litmus is very apt to change and fly. It is much employed for the purpose of giving a gloss or finish to the more deep and permanent colours, by the dyers of silk, fluffs, and ribbons. Marble soaked with litmus-liquor imbibes it in some days, and becomes beautifully tinged with a colour, which will remain for a considerable time unimpaired.

LITOTES, Διότης, in *Rhetoric*. See LIPTOTES.

LITOWISCH, in *Geography*, a town of Poland, in Vohynia; 56 miles S.W. of Lucko.

LITRA, in *Ancient Coinage*. See LIBRA.

LITRE, or *Cubie Daboire*, a French measure of capacity, equal to 60,52800 English cubic inches, or nearly 2½ wine pints. See MEASURE.

LITRON, a measure for corn and dry commodities, in the old system of France; 16 litrons being equal to a boisseau, each boisseau being = 730 English cubic inches, and 11 boisseaux = 4 English bushels.

LIEROFOND, in *Geography*, a town of Asiatic Turkey, on the south-west coast of Anatolia. N. lat. 36° 51'. E. long. 37° 35'.

LITSCHAU, a town of Austria; 70 miles N.W. of Vienna. N. lat. 49° 48'. E. long. 14° 55'.

LITTAU, a town of Moravia, in the circle of Olmutz; 8 miles N.N.E. of Olmutz. N. lat. 49° 28'. E. long. 16° 59'.

LITTER, LECTICA, a kind of vehicle borne upon staves, anciently esteemed the most easy and genteel way of carriage.

Du Cange derives the word from the barbarous Latin, *lecteria, strata* or *bedding for beasts*. Others will rather have it come from *lectus, bed*, there being ordinarily a quilt and a pillow to a litter; in the same manner as to a bed.

Pliny calls the litter the traveller's chamber; it was much in use among the the Romans, among whom it was borne by slaves kept for that purpose; as it still continues to be in the East, where it is called a *palanquin*.

The Roman *lectica*, made to be borne by four men, was called *tetratherum*; that borne by six, *hexaphorum*; and that borne by eight, *octophorum*.

The invention of litters, according to Cicero, was owing to the kings of Bithynia; in the time of Tiberius they were become very frequent at Rome, as appears from Seneca; and even slaves themselves were borne in them, though never by more than two persons, whereas men of quality had six or eight.

LITTER, in *Agriculture*, a name applied to straw, fern, or other dry substances, that are placed under horses, cattle,

&c. in the stables, cow-houses, farm-yards, or other places for the purpose of keeping the animals clean, and the providing a large supply of manure. In this last view, all sorts of dry materials should be carefully collected, and stacked up for winter use. And it is of vast importance, in different views, to have it properly employed in foddering the cattle, as well as in littering them down in the stall and yards; as, without proper economy, much disadvantage may arise to the farmer in the way of converting it into manure. See SOILING and FARM-YARD.

Merely as litter, wheat-straw is always to be preferred for horses; but for cattle and other animals, the other sort of straw, fern, &c. may answer equally well.

LITTERMORE, in *Geography*, an island on the coast of the county of Galway, Ireland. It is on the south-east of Kilkerran bay, and is about four miles long by two wide. N. lat. 53° 17'. W. long. 9° 40'.

LITTLE ALGONQUINS, Indians who inhabit near the Three Rivers, and can raise about 100 warriors.

LITTLE Bairam. See BAIKAM.

LITTLE Britain, a post-town of America, in Orange county, New York; 29½ miles from Washington.—Also, a township in Lancaster county, Pennsylvania, containing 1365 inhabitants.—Also, a township in Chester county, in the same state,

LITTLE Calfan. See CAPTAN.

LITTLE Compton, in *Geography*, a township in Newport county, Rhode island, containing 1577 inhabitants, and affording greater quantities of meat, butter, cheese, vegetables, &c. than any other town of its size. The inhabitants, who are industrious, manufacture linen and tow cloth, flannels, &c. of an excellent quality, and in considerable quantities for sale.

LITTLE Creek, a town of America, in Kent county, Delaware, containing 1908 inhabitants.—Also, a town in Sussex county, Delaware, containing 2164 inhabitants.

LITTLE Harbour. See PISCATAQUA.—Also, a bay in the straits of Magellan, on the coast of Patagonia; 5 miles N.W. of Bachelor's river.

LITTLE Island, or *Little Salvador*, one of the smaller Bahama islands. N. lat. 23° 46'. W. long. 75° 16'.—Also, an island in the river Lee, in Ireland, about three miles in circumference; 6 miles E. of Cork.

LITTLE Mays. See MAYS.

LITTLE River, in *Geography*, a beautiful and rapid river of America, in Georgia, when, at its confluence with Savannah river, it is about 50 yards wide.—Also, a river which partly separates North and South Carolina.—Also, a plantation in Kennebeck county, Maine.

LITTLE Sodus, a harbour of lake Ontario; 15 miles S. of Oswego.

LITTLEBOROUGH, a town on the west coast of the island of Nevis; 2 miles N. of Charles town.

LITTLETON, ADAM, in *Biography*, a learned philologist, was born in 1617 at Hales-Owen, in Shropshire, of which place his father was vicar. He was educated at Westminster, under Dr. Busby; and in 1642 was admitted a student of Christ's college, Oxford. He was, on account of his principles, ejected by the parliamentary visitors in 1648, and was under the necessity of obtaining a living as usher at different schools. At the restoration, he was appointed second master of Westminster school, king's chaplain in ordinary; and in 1674, having already obtained his doctor's degree, he was hurried to the rectory of Chelsea. This preferment was followed by being appointed a prebendary of Westminster, and afterwards sub-dean. He died on the 30th of June 1694, leaving behind him the character

acter of an amiable man, and very considerable scholar. He was conversant in the Hebrew, Chaldaic, and Arabic languages; and was conversant with the higher parts of mathematics. He published many works in divinity and philology, but is chiefly known for his "Latin Dictionary," which was in general use in our schools till that of Ainsworth was published. He had received a grant of king Charles II. to succeed Dr. Busby, as head master of Westminster school; but death prevented the execution of the king's intention.

LITTLETON, Sir THOMAS, an English lawyer and judge, who flourished in the fifteenth century, was eldest son of Thomas Westcote, esq. of Devonshire, by the heiress of Littleton, of Frankley in Worcestershire, whose name he assumed. He was regularly educated for the law; and, in the reign of Henry VI., he was made judge of the marshalsea court and king's serjeant, and in 1475 went the northern circuit as judge of the assize. In 1466 he was appointed one of the judges of the common pleas, and, a short time after, was created a knight of the Bath. He died in 1481, leaving three sons, from whom many considerable families are descended. He was author of a valuable work, entitled "Tenures and Tides by which Estates were anciently held in England." It was written in French, and a translation of it, with a commentary, forms the first book of Coke's "Institutes." Sir Thomas, during the troubles and confusions of the times, so comported himself, as to enjoy the favour of both the contending sovereigns; and, at the same time, acquired the esteem of all, for his great skill in the laws of England.

LITTLETON, EDWARD, distinguished for his great knowledge in the common law, son of Sir Edward, a Welsh judge, was born in 1589, and pursued his college exercises in Christ church, Oxford, from whence he removed to the Inner Temple, to pursue the study of the law. He was an active member of parliament in the year 1628, and, together with Sir Edward Coke and Sir Dudley Digges, carried up the Petition of Right from the Commons to the Lords. He was also a leading manager in the accusation against the duke of Buckingham, in which his judicious conduct obtained for him the good opinion of the prince and people. He succeeded his father as Welsh judge, and was chosen recorder of London. In 1634 he was made by Charles I. solicitor-general, and knighted; in 1639 he was sworn lord chief justice of the common pleas; and, in the following year, he was advanced to be lord keeper of the great seal of England, and called to the house of peers by the title of lord Littleton. He afterwards lost the favour of the king, though it is believed without reason, which he could never after regain. He died in August 1645, at Oxford, where he was buried on the north side of the choir in the cathedral of Christ church, and had a funeral oration pronounced over him by Dr. Henry Hammond. He published a book of Reports of Cases in the Courts of Common Pleas and Exchequer, from the second to the eighth of Charles I.; some speeches in parliament, several arguments and discourses. Biog. Brit.

LITTLETON, in Geography, a post-town of America, in Middlesex county, Massachusetts, 28 miles N.W. of Boston; containing 924 inhabitants.—Also, a post-town in Grafton county, New Hampshire, incorporated in 1784, and containing 381 inhabitants.—Also, a township, now called *Waterford*, in Caledonia county, Vermont, on the west side of Connecticut river, containing 565 inhabitants.

LITTLETON'S *Island*, a small island in the Florida stream. N. lat. 24° 42'. W. long. 81° 40'.

LITTORAL SHELLS, among writers of *Natural His-*

tory, are such sea-shells as are always found near the shores, and never far off in the deep.

Those which are found in the bottom of the sea, remote from the shore, are called *pelagian*.

LITTORELLA, in *Botany*, the diminutive of *Litus*, a shore, this plant being generally found in the neighbourhood of lakes or pools. Indeed its English name, Shore-weed, is also expressive of its place of growth. Linn. Mant. 160. Schreb. 629. Willd. Sp. Pl. v. 4. 330. Mart. Mill. Diet. v. 3. Sm. Fl. Brit. 1511. Ait. Hort. Kew. ed. 1. v. 3. 335. Juss. 60. Lamarek Illustr. t. 758.—Class and order, *Monocotyledonæ*. Nat. Ord. *Plantaginæ*, Juss.

Gen. Ch. Male. Cal. Perianth of four leaves, erect. Cor. of one petal: tube the length of the calyx; limb four-cleft, erect, permanent. Stam. Filaments four, thread-shaped, very long, inserted into the receptacle; anthers heart-shaped.

Female on the same plant. Cal. none. Cor. of one petal, conical, permanent, its mouth unequally three-cleft. Pist. Germen oblong; style thread-shaped, very long; stigma acute. Peric. none, except the permanent corolla. Seed a nut of one cell.

Eff. Ch. Male. Calyx four-leaved. Corolla of one petal, four-cleft. Stamens very long.

Female. Calyx none. Corolla of one petal, unequally three-cleft. Style thread-like, very long. Nut of one cell.

1. *L. lacustris*. Plantain Shore-weed. Linn. Mant. 295. Sm. Fl. Brit. 1511. Engl. Bot. t. 468. (Plantago uniflora; Linn. Sp. Pl. 167. Fl. Dan. t. 170.)—A native of the shores of lakes in various parts of Europe, and of marshy sandy spots in Great Britain, but not very common. It flowers in June. Root perennial, spindle-shaped. Herb smooth, stemless. Leaves linear, entire, convex underneath. Male flowers on stalks, solitary, erect, whitish, resembling those of Plantain: female ones radical, sessile, having an erect, prominent, thread-shaped style.

The whole habit of this curious genus is that of a *Plantago*, from which however it is sufficiently distinct on account of its fruit being a single seed or nut. It was originally separated from that genus, by Bergius, in the Stockholm Transactions for 1768. The Rev. Mr. Williams of Shropshire has found this plant occasionally to vary with hairy leaves.

LITURGY, denotes all the ceremonies in general belonging to divine service.

The word comes from the Greek *λειτουργία*, service, public ministry, formed of *λαός*, public, and *εργον*, work.

In a more restrained signification, liturgy is used among the Romans to signify the mass; and among us the common-prayer.

All who have written on liturgies agree, that in the primitive days, divine service was extremely simple, only clogged with very few ceremonies, and consisting of but a small number of prayers; but, by degrees, they increased the number of external ceremonies, and added new prayers, to make the office look more awful and venerable to the people. At length things were carried to such a pitch, that regulation became necessary; and it was found proper to put the service, and the manner of performing it, into writing; and this was what they called a liturgy.

Liturgies have been different at different times, and in different countries. We have the liturgy of St. Chrysostom, that of St. Peter, of St. James, the liturgy of St. Basil, the Armenian liturgy, the liturgy of the Maronites, of the Coptæ, the Roman liturgy, the Gallican liturgy, the English

English liturgy, the Ambrosian liturgy, the Spanish and African liturgies, &c.

In the more early ages of the church, every bishop had a power to form a liturgy for his own diocese; and if he kept to the analogy of faith and doctrine, all circumstances were left to his own discretion. Afterwards the practice was for the whole province to follow the service of the metropolitan church, which also became the general rule of the church: and this Lindwood acknowledges to be the common law of the church; intimating, that the use of several services in the same province, which was the case in England, was not to be warranted but by long custom. Gibb. 259.

The liturgy of the church of England was composed in the year 1547, and established in the 2d year of king Edward VI. by stat. 2 & 3 Edw. VI. cap. 1.

In the fifth year of this king it was reviewed; because some things were contained in that liturgy, which shewed a compliance with the superstition of those times, and some exceptions were taken against it by some learned men at home, and by Calvin abroad. Martin Bucer was consulted, and some alterations were made in it, which consisted in adding the general confession and absolution, and the communion to begin with the ten commandments. The use of oil in confirmation, and extreme unction were left out, and also prayers for souls departed, and what tended to a belief of Christ's real presence in the eucharist. This liturgy, so reformed, was established by the act of 5 & 6 Edw. VI. cap. 1. However, it was abolished by queen Mary, who enacted that the service should stand as it was most commonly used in the last year of the reign of king Henry VIII. The liturgy of 5 & 6 Edw. VI. was re-established with some few alterations and additions, by 1 Eliz. cap. 2. All the bishops present dissented both in this and the former acts; and, therefore, the expression "lords spiritual" doth not occur in either of them. (Gibb. 268.) Some farther alterations were introduced, in consequence of the review of the Common Prayer Book, by order of king James, in the first year of his reign; particularly in the office of private baptism, in several rubrics and other passages, with the addition of five or six new prayers and thanksgivings, and all that part of the catechism which contains the doctrine of the sacraments. The book of Common Prayer, so altered, remained in force from the first year of king James to the fourteenth of Charles II. But the last review of the liturgy was in the year 1661, and the last act of uniformity enjoining the observance of it, is 13 & 14 Car. II. cap. 4. (*See Common Prayer.*) Many applications have been since made for a review, but hitherto without success. See Free and Candid Disquisitions relating to the Church of England, &c. 8vo. Lond. 1749.

We shall here subjoin some pertinent remarks on liturgies by archdeacon Paley, together with some additional reflections. Liturgies, or preconcerted forms of public devotion, being neither enjoined in scripture, nor forbidden, there can be no good reason for receiving or rejecting them, but that of expediency; which expediency is to be deduced from a comparison of the advantages and disadvantages attending this mode of worship with those which usually accompany extemporary prayer. The advantages of a liturgy are these: 1. That it prevents absurd, extravagant, or impious addresses to God, which, in an order of men so numerous as the sacerdotal, the folly and enthusiasm of many must always be in danger of producing, where the conduct of the public worship is entrusted, without restraint or assistance, to the discretion and abilities of the officiating minister. On the other hand, the advocate for free prayer might allege, that the cases to which the ingenious author refers are of the extreme kind, that are

not likely often to occur; that a minister who is capable of addressing a congregation acceptably and usefully, would not be in danger of offending in the manner here proposed, when he conducted their social devotion, more especially as he would conceive it to be his duty to make previous preparation for the one service as well as the other; that the mode of performing public worship must be left to the choice and approbation of those who concur in it; that the occasional perversion and abuse of a privilege cannot be justly pleaded against the use of it; and that if the evil were greater than it is, there is no method of avoiding it, but by the imposition of preconcerted liturgies, which would encroach on liberty in the province of religion. Established liturgies, it might be said, are not easily accommodated to the sentiments of the worshipper, who disbelieves the creed on which they are founded; and they must lead him to the avowal of principles, and to the use of language, which his judgment disapproves. If every officiating minister be allowed to adopt his own mode of conducting social worship, whether it be by extemporary prayer, or by forms, for each of which he has made previous preparation, he is not likely to give offence to those who are with him.

Our author farther observes, 2. That a liturgy prevents the confusion of extemporary prayer, in which the congregation being ignorant of each petition before they hear it, and having little or no time to join in it after they have heard it, are confounded by their attention to the minister, and to their own devotion. The devotion of the hearer is necessarily suspended, until a petition be concluded; and before he can assent to it, or properly adopt it, that is, before he can address the same request to God for himself, and from himself, his attention is called off to keep pace with what succeeds. But the advocate for free prayer will naturally enquire, if this be not the case, in a greater or less degree, in every continued service? If he has the words before him, which he uses in his devotion does he dwell on a single sentence as soon as the officiating minister utters it? Is not his attention drawn on to succeeding parts of the prayer that is pronounced, as soon as they are delivered? But in neither case is his mind kept long in a state of suspension; and he has this advantage, that whilst he is joining in exercises of devotion with the minister of his choice, he is not likely to hesitate in concurring with him. As to the novelty with which he expects to be gratified, this may probably be more likely to excite his attention and interest his heart, than a recurrence of sentiments and expressions that are familiar to him, and which long-continued use will prevent from interesting and fixing the (perhaps) wandering mind. *Joint prayer*, it is further said by the learned archdeacon, which, among all denominations of Christians, is the declared design of "coming together," is prayer in which all join; and not that which one alone, as the congregation conceives and delivers, and of which the rest are merely hearers. This objection, says our author, seems fundamental, and holds even where the minister's office is discharged with every possible advantage and accomplishment. But in the use of preconcerted and established liturgies, are not all besides the officiating minister hearers, unless they concur in those responses, which have been observed in many instances to produce confusion, and to render devotion a kind of mechanical business? The advocate for extemporary prayer will allege, that he is not less capable of joining in a worship, conducted by a minister who uses words, suggested at the moment, than in that which is performed by a recital of words previously written or printed. The objection to this mode of public worship, founded on the labouring recollection, and embarrassed or tumultuous d-

livery of many extempore speakers, evinces the necessity of talents for the discharge of this part of public duty, and of previous preparation; but does not prove that the adoption of a liturgy is either most expedient or most useful when extempore prayer is properly performed; and it is presumed, that persons who are accustomed to exercises of devotion will acquire a facility in the performance of them, which will, in a great degree, obviate the objection now stated, and prevent the pain that would be given to the serious part of a congregation, or the profane diversion which might be occasioned by the levity of the other part.

The advantages of a liturgy, our author candidly allows, are connected with two principal inconveniences; *first*, that forms of prayer composed in one age become unfit for another by the unavoidable change of language, circumstances and opinions; *secondly*, that the perpetual repetition of the same form of words produces weariness and inattentiveness in the congregation. Both these inconveniences, however, are in their nature vincible. Occasional revisions of a liturgy may obviate the first, and devotion will supply a remedy for the second; or, as our author thinks, they may both subsist in a considerable degree, and yet be outweighed by the objections which are inseparable from extempore prayer. Nevertheless, this is a concession, which will not be admitted by the advocates of the latter mode of worship; nor adverting to past experience, since the year 1061, will they lay much stress on occasional reviews of the liturgy.

How far the Lord's prayer is a precedent, as well as a pattern, for forms of prayer, is a question, concerning which writers, who have directed their attention to this subject, are not agreed.

Archdeacon Paley specifies the following properties as requisite in a public liturgy; *viz.* that it be compendious; that it express just conceptions of the divine attributes; that it rectify such wants as a congregation are likely to feel, and no other; and that it contain as few controverted propositions as possible. As to the first property, he observes, that it would be no difficult task to contract the liturgies of most churches into half their present compass; and yet retain every distinct petition, as well as the substance of every sentiment, which can be found in them. Although our author does not admit the propriety of studying brevity too much, he is of opinion, that the too great length of church services is unfavourable to piety. It begets in many an early and unconquerable dislike to the public worship of their country or communion. They come to church seldom; and enter the doors when they do come under the apprehension of a tedious attendance, which they prepare for at first, or soon after relieve, by composing themselves to a drowsy forgetfulness of the place and duty, or by sending abroad their thoughts in search of more amusing occupation. Although there may be some few of a disposition not to be wearied with religious exercises, yet, where a ritual is prolix, and the celebration of divine service long, no effect is in general to be looked for, but that indolence will find in it an excuse, and piety be disconcerted by impatience. It might further be observed, that the extent of our established liturgy does not leave time sufficient for public instruction; that the attention is fatigued before this part of our public service commences; and that excess in our public discourses, which admit of variety, is more excusable than the same fault in our devotional exercises, during which the attention ought to be kept alive, and the understanding and heart properly engaged. Our author remarks, that the length and repetitions complained of in our liturgy are not so much the fault of the compilers, as the effect of uniting

into one service, what was originally, but with very little regard to the convenience of the people, distributed into *three*. Accordingly we observe, with the authors of the "Free and candid Disquisitions," that the Lord's prayer in particular is enjoined to be publicly used every Lord's day in our ordinary service, when there is no communion, no less than seven times, *viz.* five times in the morning and twice in the afternoon: and when there is a communion, and also afternoon sermon or lecture, then nine times: and if the office of infant baptism (to say nothing of that of adults), and the other of churching of women, happen to come in, as they may and do sometimes, both morning and afternoon, then thirteen times. The "Gloria Patri" is introduced commonly, and most usually, seven or eight times; not unfrequently nine or ten; and may also occur eleven times, in the course of our morning service only. Notwithstanding that dread of innovation, in religion, which, says archdeacon Paley, seems to have become the *panic* of the age, few, as he supposes, would be displeased with such omissions, abridgments, or change in the arrangement, as the combination of separate services must necessarily require, even supposing each to have been faultless in itself. If, together with these alterations, the epistles and gospels, and collects which precede them, were composed and selected with more regard to unity of subject and design; and the psalms and lessons either left to the choice of the minister, or better accommodated to the capacity of the audience, and the edification of modern life; the church of England would be in possession of a liturgy, in which those who assent to her doctrines would have little to blame, and the dissatisfied must acknowledge many beauties. The style throughout is excellent; calm, without coldness; and, though every where sedate, oftentimes affecting. The pauses in the service are disposed at proper intervals; the transitions from one office of devotion to another, from confession to prayer, from prayer to thanksgiving, from thanksgiving to "hearing of the word," are contrived, like scenes in the drama, to supply the mind with a succession of diversified engagements. As much variety is introduced also in the form of praying as this kind of composition seems capable of admitting.

The *second* property of a liturgy, *viz.* that it should express just conceptions of the divine attributes, is an article deserving particular care. The popular notions of God are formed, in a great measure, from the accounts which the people receive of his nature and character in their religious assemblies. An error here becomes the error of multitudes: and as it is a subject in which almost every opinion leads the way to some practical consequence, the purity or depravation of public manners will be affected, among other causes, by the truth or corruption of the public forms of worship. The *third* requisite of a liturgy is that it rectify such wants as the congregation are likely to feel, and no other. It were therefore to be wished that every part of a liturgy were personally applicable to every individual in the congregation; and that nothing were introduced to interrupt the passion, or damp a flame which it is not easy to rekindle. Upon this principle, the *state-prayers* in our liturgy should be fewer and shorter. The *state-style* likewise seems unseasonably introduced into these prayers, as ill according with the annihilation of human greatness, of which every act that carries the mind to God presents the idea. It is required, *fourthly*, that a liturgy contain as few controverted propositions as possible. Why, says our author, should every position which a church maintains be woven with so much industry into her forms of public worship? Some are offended, and some are excluded; this is an evil in itself, at least to *them*: and

what advantage or satisfaction can be derived to the *myl* from the separation of their brethren, it is difficult to imagine: unless it were a duty to publish our system of polemic divinity, under the name of making confession of our faith every time we worship God; or a sin, to agree in religious exercises with those from whom we differ in some religious opinions: indeed, where one man thinks it his duty constantly to worship a being whom another cannot, with the assent of his conscience, permit himself to worship at all, there seems to be no place for comprehension, nor any expedient left but a quiet secession. All other differences may be compromised by silence. If sects and schisms be an evil, they are as much to be avoided by one side as the other. If sectaries are blamed for taking unnecessary offence, established churches are no less culpable for unnecessarily giving it: they are bound at least to produce a command, or a reason of equivalent utility, for shutting out any from their communion, by mixing with divine worship, doctrines which, whether true or false, are unconnected, in their nature, with devotion. Paley's *Principles of Moral and Political Philosophy*, vol. ii. chap. 5. See PRAYER.

Of all the forms which Christianity has taken in different parts of the world, of all the sects which refuse communion with regular establishments, music, or rather chanting, has been the language of devotion. It has been sarcastically asked, whence this impulse to *cry aloud* originated; was it from the thundering music of the fingers of Joshua round Jericho, the sweet strains of the harp of David, the pompous and proud clangor and vociferating of the myriads of musicians at the temple of Solomon, or the pious chant of the canticle which Jesus Christ and his apostles sung at the first institution of prayer, that we derive our choirs, hymns, psalms, and spiritual songs, which in every communion of Christians constitute, and always have constituted, a considerable part of the public worship regulated by liturgies? We have no doubt but that the primitive Christians, when their religion was founded on that of the Jews, (at least as far as the belief and worship of one God,) in opposition to Paganism and idolatry, sung the Psalms of David, which they had adopted, in imitation of the royal psalmist and his nation.

But there was no Pagan temple, or sacrifice at an altar, without music, and at present, even the savages of America honour their divinities with singing. Indeed songs, of which the subject and poetry correspond with the rites and ceremonies of the Pagans, constituted all their liturgies, to the exact celebration of which it is well known they were scrupulously attached. It is true that the Christians differ very much in their musical tastes. The Quakers have no liturgy: they wait till the spirit moves them to speak, and never sing; they only sigh and groan. Calvin stripped music of harmony and measure, and allowed of nothing but unisonous and syllabic singing in the conventicles, without the assistance of that *vox of whistles*, as the Scotch reformers used to style the organ. The modern methodists like light, airy, and familiar music so much better than solemn strains of supplication, that they admit ballad and barrel-organ tunes out of the street to be adapted to their hymns. The music *a cappella*, in the cathedral service of the Roman Catholics, and Protestants of the sixteenth and seventeenth centuries, seems the most solemn and revered species of music with which to address the divinity; at least it is the most grateful to cultivated ears. In parish churches, under the guidance of a powerful organ, or a judicious chanter, psalmody in parts, provided some respect were paid to accent, and distinction were made between long and short syllables, as in the 104th psalm and other melodies in triple-time, would

cease to be absurd and ridiculous to lovers of music, and rendered a gratification, instead of a torture, to cultivated ears.

LITVINTZOVA, in *Geography*, a town of Russia, in the government of Irkutsk; 36 miles S. of Ilimsk.

LITUS, in the *Materia Medica*, the same as *lithum*; which see.

LITUUS, among *Medicists*, the staff or wand twisted round at the top, used by the augurs, made in the form of a crozier, and the badge of the augurship.

We frequently see it on medals, along with other pontifical instruments. Aulus Gellius says, it was bigger in the place where it was crooked than elsewhere. In some coins of Nero the lituus appears at his breast; and from badly preserved coins has been taken by some medallist writers for a serpent.

LITUS, in *Natural History*, a name given to a genus of shells of the class of the polythalamii, or those which consist of several concavations or chambers, parted from one another by shelly diaphragms, and communicating with one another by means of a siphonculus, which runs through the whole length of the shell. To this general character of the class, it is to be added, that the litus is always a conic shell, running in a straight line from the mouth, through a great part of the length, and from the end of this straight part to the extremity, twisting into the shape of a cornu ammonis, or spiral shell of that kind.

It is thus named from its resembling the instrument called lituus among the ancients. The stony matter often found cast in this shell, and resembling all its lineaments, is called by authors *lituitis*, as those stones formed in the peccen, peccinites, and those in the echini marini echinitæ. See CONCHOLOGY.

LITUS, in *Roman Antiquity*. The Romans had a crooked military musical instrument called a *lituus*, in the form of the augural staff, whence it had its name. It was a species of clarion, or octave trumpet, made of metal, and extremely loud and shrill, used for the cavalry, as the straight trumpet was for the foot. Horace distinguishes it from the *tuba*, or trumpet.

"Multos castra juvant, et lituo tubæ
Permissus sonitus, ———— Od. i. 23.

as Claudian does from the flute:

"Tibia pro lituis, et pro clangore tubarum
Molle lyre, fustumque canant."

On our music plates are engraved a double lituus and a straight trumpet, from an ancient bas-relief in the Vitaleschi palace at Rome, representing a sacrifice: as is a genuine ancient metalline lituus, now in the possession of the right honourable sir Joseph Banks, K. B. and president of the Royal Society. It was found with many other antiquities, both Roman and Anglo-Saxon, in clearing the bed of the river Witham, near Tatterhall, in Lincolnshire, 1761, and is perhaps the only instrument of the kind that is now extant. It is a long narrow tube, with a swelling curve at the end, like the double lituus, but resembling still more an instrument sculptured on the base of Trajan's pillar at Rome. It is neatly made of very thin brass, with three joints or pieces, like German flutes, and has been well gilt. Its length is upwards of four feet, though the upper end has been evidently broken off.

An instrument of this kind, made of cast brass, was found in digging a well, near Battle in Sussex, and was then filled with small shells. We have an engraving of it in Grose's

Military Antiquities, vol. ii. A similar trumpet is engraved in Montfaucon's Roman Antiquities.

This instrument frequently appears on ancient medals as a symbol of war, and is terminated with the head of a boar, and sometimes with that of a snake, as on an ancient family medal of Albinnus, struck during the time of the republic, between the first Punic war and the reign of Augustus.

LITYEREA, the song of the reaper, in the *Ancient Music*. Theocritus, Apollodorus, Juvenal, Pollux, &c., and others, mention this song, and call it *Lityeris*, from *Lytus*, the natural son of Midas; a rude and ferocious prince, who obliged strangers to work with him in the fields at harvest-time, and those who were too feeble and unable to work, he put to death. Midas killed him in the life time of his father.

Julius Pollux says that this song was a funeral, and sang round the sheaves, to console Midas for the death of his son.

LITZENDORF, in *Geography*, a town of Bavaria, in the bishopric of Bamberg; 6 miles E.N.E. of Bamberg.

LIVADIA, a province of European Turkey, bounded on the N. by Thessaly, on the E. by the Archipelago, on the S. by the gulf of Lepanto, which separates it from the Morea, and the gulf of Egina, and on the W. by the Mediterranean; 180 miles long from N.W. to S.E., and about 35 miles in its medial breadth. This province comprehends what was properly called Greece (see *Greece, Fregia*); and the mountains, so much celebrated by the ancients, viz. Parnassus, Helicon, and Cythæron. The places that are now most noted in it are Lepanto, Livadia, and Athens.

LIVADIA is also a large, populous, commercial town, in the province of the same name, situated near the gulf of Lepanto, and built round a mountain terminating in a peak, and on which is a castle; 28 miles N. of Corinth. N. lat. $38^{\circ} 37'$. E. long. $23^{\circ} 54'$.

LIVADOSTA, a town of Livadia, on the E. extremity of the gulf of Lepanto; 20 miles S.E. of Livadia.

LIVAROT, a town of France, in the department of the Calvados, and chief place of a canton, in the district of Lisieux; 8 miles S.S.W. of Lisieux. The place contains 1210, and the canton 11,279 inhabitants, on a territory of 195 kilometres, in 20 communes.

LIUBIM, a town of Russia, in the government of Jaroslavl; 40 miles N.E. of Jaroslavl. N. lat. $58^{\circ} 55'$. E. long. $40^{\circ} 50'$.

LIUBITCH, a town of Russia, in the government of Tchernigov, on the Dniéper; 20 miles W. of Tchernigov. N. lat. $51^{\circ} 22'$. E. long. $25^{\circ} 44'$.

LIUDER, a town of Sweden, in the province of Smaland; 31 miles W. of Calmar.

LIVE CAVES, in *Mining*, a phrase used by many people to express such caverns in the earth as have but little communication with the external air, and are found to abound with mineral productions. The workers in the lead-mines on islands thus distinguish the numerous caverns in those places into the *live* or *quick* caves, and the *dead* caves; the latter are such as admit the air into them two or three ways, and are barren of any thing valuable; the others have only one passage, and that but narrow and winding, and generally lie at great depths. These abound in numerous elegant productions. They almost always contain ore in some form or other, and usually abound in elegant spar. Mr. Beaumont mentions one of these in the Philosophical Transactions, which lay at thirty-five fathoms perpendicular depth, in which there was found a fine liver-coloured earth, of the nature of bole arménia, which in many places shoot

up in a wonderful manner in a sort of spires of the height of three or four inches, formed with ridges and furrows, and usually covered with spar at the top; sometimes all the way down, to the bed of earth. Phil. Trans. N^o 129.

LIVE EVER, in *Botany*. See ORPINE.

LIVEN in *Idleness*. See VIOLET.

LIVE HEDGES, in *Rural Economy*, such as are constituted of living materials, such as white-thorn plants, &c. See TERN.

LIVE-STOCK, in *Agriculture*, is a term which signifies all that sort of animal flock which is raised or kept upon a farm, either for the purpose of use or profit. It comprehends all sorts of domestic animals, whether those of the cattle, horse, and swine kind; or those of the rabbit and poultry descriptions. In one of the reports of the state of agriculture, drawn up for the board, it is stated that this is a subject which "is, perhaps, the most important in the whole range of rural economies. The poorest and most backward nations contrive to raise bread for their consumption, equal to the demand; and to increase the quantity with the increase of their mouths. Their wheat, in the most miserable husbandry, is nearly equal, and much of it superior, to that of our highly cultivated fields; and we feel constantly in our markets the effect of their competition: but with all that concerns live-stock the case is abundantly different; it is by great exertions only that a people can be well supplied, and for want of such exertions, many nations are forced to content themselves with such meat as others would not touch. Look at a sample of French and Swiss wheat, no difference is found; but examine the cows of Switzerland and Lorraine, what a difference! Compare the mares of Flanders with the ponies of Bretagne, the sheep of England and of France: nay, let us come nearer home, and reflect on the wool in competition; examine the fleeces of Segovia and of Italy, in the same parallel of latitude." And it is added that, "next to the cultivation of waste lands (which by the way much depends on the well ordering of live-stock), this, it is conceived, is the greatest desideratum in the agriculture of Britain."

And it has been remarked by the author of "Practical Agriculture," that there is scarcely any branch of husbandry that is of more consequence to the farmer, or which, of late, has been more attended to and improved. He supposes, indeed, that it might easily be imagined that, as the means of supporting domestic animals become more perfectly known, and more extensively provided, great and beneficial changes would take place in the nature, form, and other properties of the animals that were to be kept for the purposes of the farmer, and consequently advantages to be derived both in the amelioration of the land and the improvement of the live-stock, which it supported. It is also conceived, that the greatly increased demand for this sort of flock, either for the purposes of food or labour, may have likewise had much effect in promoting and forwarding their improvement; but that, though much has lately been accomplished in this department of rural economy, much still remains to be done, which may in some measure be effected by the judicious combination of proper improved breeds of animals of different kinds, with the various improvements in the cultivation and management of herbage or other sorts of green food by which they are to be supported.

Mr. Middleton likewise contends that, where it is intended "to attempt any considerable improvement in the nature of the live-stock of a farm, care should be previously taken that there is a sufficient degree of shelter, shade, and warmth, as well as a high degree of fertility of the land, and a suitable

able state of drainage, as it is only by the richness and abundance of food that such changes can be effected in the most advantageous way, or the flock be brought to any high degree of perfection." The circumstances which are to be more particularly considered, in undertaking improvements in the nature of live-stock, especially in what relates to themselves, are those of the shape, the size, the disposition, the hardiness, the arriving quickly at maturity, the peculiar nature of the flesh, the property of fattening with expedition, the affording milk in sufficient plenty, the quality of the hide, the fitness for performing labour, and the particular quality or nature of the breed, of whatever sort of animal it may be. All of which are particularly considered in explaining the nature and methods of management that are the most proper to be adopted in breeding, rearing, and bringing to perfection different sorts of animals of the domestic kind for the uses of the farmer. See BREEDING.

In respect to the introduction of all sorts of live-stock upon a farm, the cultivator should constantly and carefully consider the nature and extent of his keep, or the means which he has of providing them with proper supplies of proper kind of food, as on this, the size and other properties of the animals must in a great measure depend. The idea of good keep is constantly necessary to be kept in view, as without it, little can be effected in this part of husbandry. It has been forcibly remarked by the writer of the Staffordshire Agricultural Report; that "all good stock must be both bred with attention and well fed; and that it is necessary, that these two essentials in this species of improvement should always accompany each other; for without good resources for keeping it would be in vain to attempt supporting a capital flock, and with such resources, it would be absurd not to aim at a breed somewhat decent in quality." This sort of improvement must, however, be much regulated by the circumstances of the farmer, and be often only gradually effected on account of the want of money for the purpose of making a more full change in the flock of the farm.

In the Agricultural Report for Perth, it is stated, that, "there is one circumstance, relative to the introduction of all new breeds, which must not be passed over in silence, because no farmer can neglect it without a certain loss. Every kind of pasture is fitted to raise animals to a particular size. When beasts of a larger size are brought in, than the quality of the food is calculated to support, these animals, whether cows, or horses, or sheep, or any other kind, will degenerate apace, and never prove useful, until they come down to that standard or size adapted to their situation and suited to their food." And that, "on the other hand, when a smaller breed than ordinary is brought in, they continue to increase in bulk, until they come up to the pitch which is suited to their nourishment. But there is this remarkable difference betwixt these two progressions, in respect to profit, that in the retrograde progress, when animals are brought from rich pasture and a comfortable situation to the reverse, they are in every instance worse than the indigenous breed; whereas the animals, which are brought from worse to better, continue to improve, till they arrive at that perfection, which the change in their situation is calculated to produce. These changes may not immediately have their full effect; but in a few years they certainly and evidently will. He makes, for this reason, a much safer experiment, who brings cattle from worse to better, than he who brings them from better to worse. This reasoning applies to all plants, as well as animals. Highland cattle rise to a great size, not only by the keeping in South Britain, but in rich pastures at home." And

he adds, that it is "in vain to attempt to improve a breed of animals beyond the circumstances of the country as to climate and pasture; while, at the same time, it is no easy matter to discern, without proper trials, how far these circumstances can support a better flock. There is great room, he supposes, for the ingenious to exercise their judgment in improving the breeds of different animals. One species has evidently degenerated in this country, by a change in their situation to the worse. The red or forest-deer is but a puny animal in comparison of those of former times. This will be apparent to any person, who compares the horns of a deer that is killed at present to those of the same species, which are in different places dug out of the mosses. The cause is obvious." It is therefore conceived, that "the improvement of the soil ought to go hand in hand with the introduction of a larger breed of cattle; and a large breed ought, for the same reason, to be introduced, in that degree, in which the style of agriculture is improved."

In support of this, Mr. Middleton, in the Agricultural Report of Middlesex states, that "the richest grazing land, and the most nourishing artificial food, will certainly pay more in feeding large bullocks, sheep, and swine, than it would do in feeding the smaller sizes of the same species," and that "it is equally obvious that the smaller breeds will answer better on the poor pasture than the large."

Further, the particular qualities which the farmer has in contemplation, is likewise a point which must be attended to in fixing upon breeds of domestic animals for particular farms. Considering the various breeds of domestic animals, as the machines by which the farmer is enabled to send his herbage and other sorts of food to market, Mr. Donaldson thinks he ought, by the study of every proper mean, to advance their improvement, in respect to form as well as the disposition to fatten, that the produce of his farm may be disposed of in the most advantageous manner; and that besides the benefit he would derive individually, from their being thus rendered less tedious in the process of fattening, and less productive of offal, the community would gain vast advantage in the great increase of animal food.

As soon as proper sorts of live-stock have been introduced according to the particular circumstances of the land, the farmer should be extremely careful in the management of them, whether they be of the cattle, sheep, or other kinds, in the providing them with due and full supplies of food, whether in the changes of pasture during the summer season, or in that of other sorts in the winter, so as to keep them constantly in a proper thriving condition; in affording them suitable degrees of shelter and warmth, and in having them properly littered down, when confined to the yards or stalls; and under all circumstances well supplied with good water; as all these have much effect in promoting the improvement of the stock, and, of course, that of the advantage of the farmer: different methods are pursued in different districts, with this view, in animals of different kinds, which will be particularly noticed under the heads to which they belong. See CATTLE, SHEEP, HORSE, SWINE, &c.

In many parts of the island, great advances have been made to a more perfect state in the nature of different sorts of live-stock, by selecting and employing the best and most perfectly formed animals, both male and female, but especially the former, as stock to breed from; and in the midland, as well as some other counties, vast advantage has been gained in the same view, by the practice of the large and more opulent breeders and graziers letting their superior male stock of different kinds of animals; and it would probably still further promote this material object, if the more extensive proprietors

proprietors of lands were attentive to the circumstance, by either providing such male flock themselves, or enabling their tenants effectually to do it, where their situations render it impossible. By some well concerted plan of this nature, a great and general change, fous to render the different sorts of domestic animals much more perfect than they are at present, as well as better adapted to their situations, might be effected. But without some sort of aid of this kind it does not seem probable, from the great expence attending the business, that any general improvement of them can take place, though it may be carried to a considerable extent in particular cases and circumstances.

LIVENSK, in *Geography*, a town of Russia, in the government of Voronez; 36 miles W.S.W. of Voronez. N. lat. 51° S. E. long. 38° 14'.

LIVER, in *Anatomy* and *Physiology*, is the largest gland in the body, and performs the secretion of the bile. That fluid is conveyed from the liver by its excretory duct, called the hepatic; which sometimes transmits it to the duodenum, and sometimes, through a second tube called the cystic duct, into the membranous bag connected to the liver, and named the gall-bladder. The anatomical description of these organs, and the explanation of their functions are, the objects of this article.

The liver is a single organ, like the others of the organic life, not symmetrical in its figure, yet tolerably constant in its peculiar shape; occupying the upper part of the cavity of the abdomen, where it is placed obliquely from right to left, the thickest portion filling up the right hypochondrium, or space included by the false ribs of the right side, and the thinner part extending across the middle of the body in the epigastric region to the left hypochondrium. It is more deeply covered by the ribs in the male than in the female sex. In general it is smaller in proportion as the individual is more healthy: it generally becomes enlarged in size when diseased.

It is situated immediately under the diaphragm, of which the tendon intervenes between it and the pericardium; and above the stomach, arch of the colon, duodenum, little omentum, gall bladder, and right kidney. Behind, it lies against the vertebral column, the crura of the diaphragm, the œsophagus, the aorta and the inferior vena cava: and it is bounded in front by the cartilaginous edge of the chest. The right false ribs are on its right, and the spleen on its left.

The pressure of the surrounding organs just enumerated, the connection which the inferior vena cava has to it, but more particularly certain folds of peritoneum, called its ligaments, retain it in its situation, leaving it however a considerable power of changing its relative position. Anatomists enumerate four or five ligaments, all of which connect the liver to the surface of the diaphragm; but they seem to be merely so many parts of one and the same production. From the middle of the diaphragm, beginning at the apex of the ensiform cartilage, and extending backwards with a little obliquity to the right, and from the aponeurosis of the transversus abdominis, almost as low as the navel, a fold of peritoneum, consisting of two laminae, a right and left, passes to the convex surface of the liver, and is attached to it from the fossa umbilicalis to the notch that receives the vena cava. This, which is called the ligamentum latum, or suspensorium hepatis, is narrow below and in front, grows broader in the middle, where it arrives at the diaphragm, and then becomes again very narrow behind: it possesses in fact a falciform shape, the convex margin being turned upwards, the concave downwards, and the apex backwards. The front and lower edge of the ligament is

thick and rounded, and contains the remains of the umbilical vein of the fetus, surrounded by more or less fat; this part, which is implanted in the front notch of the liver, is called the ligamentum teres hepatis. The two sides of the ligament consist of broad and smooth surfaces; of which one is turned forwards and in contact with the parietes of the abdomen below, and the diaphragm above; the other, turned backwards, lies against the liver above and the abdominal viscera below. Besides the umbilical vein, the two layers of this ligament include several lymphatic trunks proceeding from the liver to the chest. Its laminae are continuous on one side with the peritoneum lining the abdominal cavity, and on the other with the external peritoneal covering of the liver. Its functions seem rather connected with the transmission of the umbilical vein, than with any confinement of the liver to a particular situation: for all the broad anterior portion is so loose, that it does not at all limit the motions of the organ: where it is narrower, it may perform this office. It will confine the liver principally in its lateral motions. It is said to have been sometimes deficient; but the observation appears doubtful.

The two laminae composing the broad ligament separate from each other towards the posterior part of the organ, and, as they proceed towards the right and left sides, take the names of right and left or lateral ligaments of the liver. These connect the respective lobes to the diaphragm; they have a triangular form; one side is loose, one connected to the liver, and the third to the diaphragm. They consist, like the broad ligament, of two layers of peritoneum, including a small quantity of cellular substance, and some lymphatic vessels. The left is commonly rather larger than the right.

The coronary ligament of the liver is a broad adhesion between the posterior part of the organ and the surface of the diaphragm: the two parts are united by a close cellular tissue through a surface of considerable extent. The boundaries of this union are formed by a very short reflexion of peritoneum, by the broad ligament in front, and by the lateral ligaments at the sides. The nature of the connection between the liver and diaphragm, will be best understood by observing the surface of the former after it has been removed from its situation. We then see the two laminae of the broad ligament separating from each other behind, and departing towards each side to form the lateral ligaments, which are also connected in a straight line along the back edge of the liver. The broad space, included between all these parts, and forming a surface of adhesion between the liver and diaphragm, is the coronary ligament. This connection acts very powerfully in maintaining the organ in its proper position, and preventing it from moving loosely in the abdomen.

We should also enumerate, among the connections of the liver, a portion of peritoneum passing from it to the right kidney; and the little omentum which joins it to the stomach. (See *EPITOMON*.) It must be remembered, that the connections just enumerated do not support the weight of the liver in the living subject, as they appear to do after death, when the abdomen has been laid open. In that case the liver sinks downwards from the diaphragm, becomes separated from it by a considerable interval, and is supported in a great measure by the broad ligament. During life the surrounding organs maintain the liver in its place, and these are all supported and held in their respective situations by the action of the respiratory muscles. Hence the organ is liable to changes of position according as these parts are moved, and it may be very variously affected in this way, as there are so many organs in contact with it. Whenever the diaphragm

diaphragm descends, the liver is carried downwards; and it moves in the contrary direction again when this muscle passes towards the chest. In the latter state, the thin edge of the liver is completely covered by the margin of the chest; hence, when we wish to press on the liver, we direct the patient to inspire strongly, that its edge may be thrust below the ribs. Effusion into the chest drives downwards both the diaphragm and liver: dropsy, pregnancy, or any other swellings in the abdomen, push them up towards the chest. When the stomach and intestines are empty, the liver descends: in the opposite state of these parts it is pushed upwards: hence the descent of the diaphragm is performed less easily after a full meal. In any erect posture of the trunk, the liver descends about two finger's breadths, and is higher in about the same proportion in the recumbent posture. When we lie on the right side, the liver is supported in the concavity of the corresponding false ribs, and presses on none of the surrounding organs; hence we commonly sleep in that attitude. In lying on the other side, the weight of the liver comes upon the stomach, which produces unpleasant feelings after a meal. Besides these changes of position, which may happen generally in any subjects, there are others of a more peculiar and individual nature, arising from different size of the organ, greater or less concavity of the diaphragm, &c. However the position may be altered, the relations to surrounding parts are the same.

The volume of the organ varies according to age, regimen, and disease. The former varieties will be considered in speaking of its development. In general, it is the largest and heaviest viscus in the abdomen. It has been observed to be largest in those who lead an inactive life, and who indulge in the pleasures of the table: the ancient epicures used to produce an inordinate growth of the liver in geese by particular diet and management. But the most remarkable variations in the size of the liver are those which occur in chronic diseases: sometimes it is diminished and very manifestly indurated; much more frequently it is enlarged, sometimes so much as to weigh ten or twelve or even more pounds. When it increases in this way, it usually takes up a proportionally greater room in the abdomen. Byer, however, saw it weighing eleven pounds, without having passed beyond the edge of the chest: it had driven the diaphragm upwards, almost to the first rib, and had reduced the right lung to a very small volume. The subject was exceedingly fat. (*Traité d'Anatomie*, tom. iv. p. 393.) The ordinary weight of the liver in a healthy adult is about three pounds: Sæmmering says it may vary from two to five pounds. Its specific gravity is to that of water as 15.03 to 10000.

The colour is a brownish-red, often inclining towards yellow. It is influenced very considerably by the quantity of blood in the vessels, and consequently is different in different modes of death. The organ is very pale in death from hemorrhage, and of a deep colour in cases where its venous system is much dilated. Its derivations from the brown-red, which constitutes the proper liver colour, are generally into lighter and particularly yellow tints. The edges and inferior surface are often quite livid. The colour on the whole is clearer the younger the individual.

The figure of the liver is so irregular, that it is not easy to describe it with clearness: we may state generally that it is thick towards the right and back part, thin towards the left and front, flattened from above downwards, and elongated rather obliquely from the right and below, towards the left and upwards. We distinguish in it a superior and inferior surface, an anterior and a posterior edge, a right and a left extremity.

The superior or convex surface, is convex, and adapted every where to the hollow of the diaphragm, to which it is contiguous throughout, except at the back part, in the situation of the coronary ligament, where it adheres firmly to the organ. The convexity is much greater behind and towards the right, than in front and on the left. Its particular direction is such, that on the left it is turned upwards and rather forwards; in the middle upwards and rather more forwards; and on the right, backwards, upwards and outwards. It is divided into two parts, called lobes, by the broad ligament; the right division, which is very much the largest, forms the right or great lobe; and the left the left or small lobe.

The inferior or concave surface is a little inclined backwards, rather less extensive than the preceding, and slightly and unequally concave. It exhibits eminences and depressions, arising apparently from the relations of the organ to the surrounding parts, and deep notches giving passage to blood-vessels, which, as in all important viscera, are formed in the most concealed situation about the organ. The following are the objects which this surface presents in succession from left to right. In their figure and arrangement they are subject to such numerous varieties, that hardly any two livers agree together in this respect.

1. A broad superficial depression corresponding to the superior surface of the stomach, and belonging to the left lobe.

2. The horizontal fissure or longitudinal groove (*fossa umbilicalis* or *longitudinalis*, or *sinistra*) divides all the inferior surface from before backwards; from the anterior edge to the left side of the passage of the inferior vena cava, and thus marks the separation of the right and left lobes on their surface. The sides are sometimes partially united by a small portion of liver, so as to form a canal. Its anterior part lodges the umbilical vein, and the posterior narrower portion (*fossa ductum venosi*) contains the *canalis venosus*, which, like that vein, is changed in the adult into a kind of ligament.

3. The great transverse fissure (*fossa transversa*, or *vena portarum*,) is placed nearer to the posterior than to the anterior edge, and runs from right to left in the direction of the great diameter of the inferior surface, of which it occupies about the middle third portion. It intersects the horizontal fissure at right angles. Its depth is considerable, particularly in the middle, and it is never covered by these transverse bridge-like portions, which have been mentioned in the former fissure. It is occupied by the trunk and first division of the *vena portarum*, by the primary ramifications of the hepatic artery, and by the biliary tubes, which unite at their departure from the liver into a single duct. The lymphatics and nerves of the liver are seen also in this situation. These parts are all united by a tolerably close cellular tissue.

4. Two eminences, sometimes called *portæ*, of which one is placed before and the other behind the middle of the great transverse fissure. The former (*lobulus quadratus* or *anonymus*) is broad and slightly elevated, resembles a more or less regular parallelogram, and varies in size, according as the gall-bladder and transverse fissure, which bound it, are more or less approximated. It extends even to the front edge, and separates the anterior half of the horizontal fissure from the gall-bladder. The other eminence has been called the small lobe of the liver, (*lobulus Spigelii* or *papillatus*.) It is sometimes triangular and sometimes quadrilateral in its figure. It is more prominent than the preceding, and placed at the posterior edge of the liver, under the trunk of the *vena portarum*. It is single in this situation, and rests on the ver-

tebra,

between the vena cava and œsophagus; thence it ascends towards the front on the inferior surface of the liver, and is immediately divided into two other small eminences. One of these is superior and posterior (lobulus caudatus), connects the small lobe to the rest of the liver, and passes obliquely towards the right, separating the vena portarum from the vena cava. It then becomes broader, and forms a short superficial groove, continuous with the right extremity of the transverse fissure, and on which the vena portarum rests as it enters that fissure. The other eminence is more considerable, and forms a kind of obtuse papilla directed forwards and downwards: this is the part properly called lobulus Spigelii. Separated from the rest of the liver in front by the transverse fissure, behind by the vena cava, on the left by the horizontal fissure, and the canalis venosus contained in it, on the right by the vena portarum before its entrance into the transverse fissure, this eminence appears to be connected to the organ only by the kind of rib just described, and which passes under the right lobes, between the vena cava and vena portarum. But behind it is farther connected by a small elongation, formed sometimes by the substance of the liver, sometimes by a fold of peritonæum, which serves to complete a very short canal traversed by the vena cava. This lobulus Spigelii is placed between the two orifices of the stomach: it corresponds below to the pancreas, above to the right and left lobes: in front of it is the falciform omentum.

5. In the right lobe, in the front of the right extremity of the transverse fissure, and on the right of the lobulus quadratus, appears the excavation that lodges the gall-bladder. This is of an oval figure, superficial, more or less distant from the longitudinal fissure, not covered by peritonæum, and lined only by the proper membrane of the liver, and by cellular tissue, which connects it strongly to the gall-bladder.

6. Two still more superficial excavations are found quite to the right. The anterior corresponds to the hepatic flexure of the colon, and the posterior to the right kidney and renal capsule.

The anterior or thin edge of the liver is thin, and inclined downwards. In the natural situation of the organ it corresponds nearly to the level of the basis of the chest, being sometimes a little above, but seldom below it. Its direction may be easily conceived from the general description we have given of the organ. It is turned almost directly downwards on the right, and becomes more directly anterior towards the left. A notch is always seen in it towards the left, and forms the commencement of the horizontal fissure: to the right of this there is a broader superficial excavation accommodated to the fundus of the gall-bladder.

The posterior or thick margin is inclined upwards, not so long as the anterior, very thick on the right, and grows gradually thinner towards the left. Its middle is closely connected to the diaphragm by the coronary ligament; and the extremities are more loosely attached to the same organ by the lateral ligaments. Two excavations may be observed on this edge: a very deep and narrow one at the posterior edge of the horizontal fissure, between the great lobe and the lobulus Spigelii, for the passage of the inferior vena cava; in this the orifices of the hepatic veins are seen. It is very slightly oblique from the left and below to the right and upwards, and covers about three-fourth of the circumference of the vein, sometimes indeed the whole of it, forming a complete canal in the substance of the liver. The second hollow, much broader and more superficial, formed in the left lobe, corresponds to the vertebral column, the aorta, and œsophagus.

The right extremity of the liver is situated much lower than the left, and is the most bulky part of the organ. The left is very thin, extends more or less into the left hypochondrium, reaching above the spleen in some subjects.

Organization of the liver.—This is very complicated; besides its peculiar tissue or parenchyma, the nature of which is perhaps more obscure than that of other glands, it receives a larger number of vessels. The greater part of the blood, brought from the placenta to the fœtus by the umbilical vein, circulates through this organ; in the adult we find only some impervious traces of this vessel. A peculiar venous system, that of the vena portarum, is at all ages entirely distributed in the liver. To these two orders of vessels, which are not found in other situations, we must add the ramifications of the hepatic artery and veins, the nerves, which are small for the organ, the lymphatic vessels, the excretory tubes, and the peculiar tissue inclosed by a double membrane; all of which must be separately considered.

Of the umbilical venous system, which is so remarkable in the fœtus, nothing more can be discerned in the adult than the fibrous remains of the umbilical vein and canalis venosus in the horizontal fissure of the liver.

The general arrangement and the organization of the vena portarum are described in the article HEART, under the head of *Arterial System of the Blood*. We have to add here only a few details belonging to their description.

1. A number of veins varying from three or four to seven or eight, of considerable size, come out of the spleen, and run tortuously in the field of peritonæum, which fixes that organ to the stomach. After a short course, in which they receive branches from the latter, they unite near the pancreas into a single trunk, called the splenic vein.

2. The pancreas produces a considerable number of small irregular branches, joining indifferently either of the principal trunks of the vena portarum, but more particularly the splenic vein.

3. Five orders of venous branches come from the stomach, and end either in the trunk or in the large branches, which make up the vena portarum.

1. Several go from the great extremity to the constituent branches, or to the trunk of the splenic vein. 2. The pyloric vein, belonging to the small curvature, opens into the trunk of the vena portarum. 3. The superior gastric or coronary stomachic vein, following the artery of the same name, joins the splenic trunk.

4. 5. The right and left inferior gastric veins run along the great curvature, and join respectively the trunk of the vena portarum, and the splenic vein.

3. The duodenal veins join either the right inferior gastric, the superior mesenteric, or vena portarum.

5. The veins of the small intestine anastomose, like the arteries, and form a most extensive net-work between the two laminae of the mesentery. The communications become fewer and the trunks larger, in proportion as they are more distant from the intestine: they form at last 15 or 20 veins, which join successively the large trunk of the superior mesenteric vein accompanying the artery of the same name.

6. The veins of the cæcum, right portion of the colon, and right side of the arch, follow the course of the arteries, and end, under the names of ileo-cæcal, right colic, and middle colic, in the trunk of the superior mesenteric.

7. The veins, which return the blood from the left side of the arch of the colon, from the descending colon, the sigmoid flexure and rectum, form as many principal branches as there are chief divisions of the inferior mesenteric artery: a large trunk, accompanying that artery, is formed by their union,

union, and is called the inferior mesenteric vein. From the rectum, of which the veins are often called the hæmorrhoidal, the inferior mesenteric trunk ascends parallel to the intestine, goes behind the transverse mesocolon, and terminates behind the pancreas, at a right angle, in the splenic vein. This vein is very small at its origin, where it anastomoses with those of the hypogastric plexus: it grows larger as it ascends, and is nearly equal in diameter to the superior mesenteric vein at its termination.

Thus we observe, that there are two principal trunks forming the vena portarum, and receiving nearly all the veins of the organs, from which this peculiar venous system derives its origin; these are the superior mesenteric and the splenic; some branches, however, directly join the trunk. The splenic, formed in the manner already specified, is not tortuous like the artery, runs in company with, but below it, along the upper edge of the pancreas, in an horizontal direction from left to right. In front of the vertebral column it ends, at nearly a right angle, in the vena portarum. In this course it receives veins from the great end of the stomach, the left inferior gastric vein, the inferior mesenteric, the superior gastric, and several pancreatic veins. The superior mesenteric vein, in the greatest part of its course, accompanies the artery of the same name, being placed to the right, and a little in front of it. It arises where the artery ends, that is, near the cæcum and the right side of the colon; it ascends, following the same course with the artery, between the two layers of the mesentery, and becomes larger as it receives new branches. At the posterior edge of the mesocolon it goes behind the pancreas, and joins at a somewhat obtuse angle the splenic vein, to form the trunk of the vena portarum, or the ventral or abdominal vena p., as it is sometimes called, to distinguish it from that end which ramifies in the liver, and which is called the hepatic vena p. In this situation it is more than an inch distant from the end of the inferior mesenteric vein. It receives, on the concave side of its curve, the three veins from the right portion of the large intestine; on the convex or left side the numerous veins of the small intestine. Several duodenal and pancreatic veins join it where it passes between the duodenum and pancreas.

The trunk of the vena portarum, the diameter of which is much less than the united diameters of the two preceding veins, goes obliquely upwards to the right, and a little backwards, and passes through a space of about four or five inches in the adult, from the vertebral column to the great transverse fissure of the liver. At first it is situated behind the right extremity of the pancreas, and the second portion of the duodenum; it then forms a part of the fasciculus of biliary vessels contained in the capsula Glissoni (see EPIPLOON), where the biliary ducts and the hepatic artery cover it in front. Like the last mentioned parts, it is surrounded by numerous nerves, lymphatic vessels and glands; and these organs are all connected by a tolerably dense and copious cellular tissue. When the trunk has arrived at the notch of the liver, it is bifurcated, and each branch forms with it nearly a right angle; so that the two taken together represent a horizontal canal lying in the notch of the liver, connected closely on each side to the corresponding divisions of the hepatic artery, and having the trunk of the vena portarum opening perpendicularly into its middle. This canal, sometimes called by anatomists the sinus of the vena portarum, does not immediately touch the substance of the liver; a thick layer of dense cellular tissue separates it, and is continuous with the general external covering of the divisions of the vein in the organ. The right branch, shorter, but much larger than the left,

enters the great lobe by the corresponding extremity of the transverse notch, and divides into an uncertain number of branches. The other passes horizontally towards the left, as far as the notch containing the umbilical vein, of which the remaining fibrous cord is firmly attached to it, and splits into branches distributed through the left lobe. The primary and secondary divisions generally pursue a horizontal course; they then divide into an infinite number of ramifications, the distribution of which we cannot regularly follow, and which end at last in a capillary system extending throughout the substance of the organ. Each of the ramifications, which we can easily trace in the liver, is accompanied by a branch of the hepatic artery, by one or more biliary ducts, some nervous filaments, and lymphatic vessels. These parts are connected and surrounded by a fine layer of cellular tissue, which adheres closely to the substance of the liver, and is often described by the name of capsule of Glisson; it seems to insulate the parts which it surrounds, as it separates them from the proper tissue of the liver. It has no connection with the peritoneum, and the suppositions of its muscularity and its propelling the blood by that power are supported by no proofs whatever. Boyer regards it as a prolongation of the proper membrane of the liver, which, he says, is reflected over all the vessels that enter or quit the organ. As the parts contained in these capsules are connected to each other by loose cellular tissue, which enters the liver with them, the orifices of the vena portarum, on a section of the organ, have a loose plaited appearance, distinguishing them from those of the hepatic veins, which, as they are intimately connected to the proper tissue of the liver, preserve their circular area, and present a much cleaner cut.

The hepatic artery is a branch of the celiac trunk, and has been described in the article ARTERY. Its branches enter at the great notch, and every where accompany the ramifications of the vena portarum.

The description of the hepatic veins is given in the article VEIN. We have to notice here only the circumstances that deserve attention, concerning their distribution in the liver. They return, to the general venous system, the blood which is brought into the liver both by the hepatic artery and the vena portarum. They arise, therefore, out of the capillary system, in which the two orders of vessels, just named, terminate. They unite successively into larger and larger branches, which form ultimately three principal and some smaller trunks, opening into the inferior vena cava, just under the diaphragm. This proximity to the heart accounts for their being so often distended with blood in the dead body. Besides the direction, in which the blood passes through them, the hepatic veins are distinguished by two principal circumstances. Their sides are rather thinner than those of the vena portarum; and they have no trace of the cellular covering, described above, as belonging to the ramifications of the latter vessel, but adhere immediately to the tissue of the liver, so as to present a perfectly circular area on a section.

The nerves, which are small in comparison to the bulk of the organ, come chiefly from the plexus of celiac ganglia; but several filaments from the eighth pair join these. See NERVE.

The lymphatic vessels of the liver are very numerous, inasmuch that no other organ seems to be more abundantly supplied with them. They are distinguished into two orders, the superficial and the deeper seated. The former cover the whole external surface, and are easily distinguished by the contrast of their colour with that of the tissue of the liver. The latter, arising in the substance of the organ, follow the

the ramifications of the vena portarum and the hepatic artery. They communicate frequently together, and end by numerous trunks in the thoracic duct, after passing through different glands.

The biliary ducts arise in all parts of the liver by capillary extremities, which are too minute for our most delicate means of research. They unite together, in the manner of veins, into larger and larger trunks, which at last end in producing two or three principal ones, quitting the liver at the transverse notch, and then united into a single tube, of about a line and a half in diameter, called the hepatic duct.

All the branches of the hepatic duct in the liver, accompany the divisions of the vena portarum, and are inclosed with them in the cellular covering already described. They are easily distinguished, on a section, by the yellow tint which they acquire from the transudation of the bile, and the orifices are then called *pori biliarii*. Indeed, we may easily distinguish, on a cut piece of liver, all the vessels belonging to it. The yellow colour and greater thickness mark the biliary tubes; the coats of the arteries are not quite so thick, and not coloured; the branches of the vena portarum are next in order of thickness, and are remarkable for their cellular covering; the hepatic veins are the thinnest.

Whether the capillary beginnings of the biliary ducts come from the acini of the liver, and concur with the capillary blood-vessels in forming those acini, is a point which we really cannot determine.

Of the peculiar tissue or parenchyma of the liver.—The substance of the organ is next, in point of density, to that of the kidney; yet it yields with tolerable facility to the pressure of the finger.

When we cut into its substance, we observe the colour distinguished from that of the exterior by a slight yellowish tint. It is porous from the great number of vessels distributed through it, and several yellow points are distinguished, which are the small biliary tubes. The different orders of vessels may be recognized by the characters already explained; the veins contain more or less blood, which may be easily squeezed out. The cut surface is smooth, and made up of small points alternately of a reddish-brown and an obscure yellow. The substance of the organ may be easily torn; the surface is then unequal and granular, composed indeed entirely of small granular bodies with every variety of figure, about the size of millet seeds, of an obscure red colour, and soft consistence. These are the acini of anatomists, and are united together, as well as all the vessels that ramify in the organ, by a fine cellular tissue. Long controversies have existed concerning their nature; but we have nothing to add on this subject to what we have stated in the article *Gland*.

In fact, we are entirely ignorant of the nature of these small bodies, which compose the proper tissue of the liver, and we know no more concerning its minute organization than about that of other parts. We see blood-vessels both of the arterial and venous kind, a peculiar order of veins not found in other organs, lymphatics, excretory tubes, nerves, small soft and reddish granular bodies, cellular tissue to connect all these together, and common coverings to insulate the organ; such is the account of our knowledge concerning the organization of this part. Chemistry does not disclose to us any thing more satisfactory; we know that it is the slowest of all parenchymatous organs in putrefaction, after the kidney; that it loses much of its weight, and acquires something of a fatty nature by drying; that it is softened by ebullition; dissolved in sulphuric acid, which it tinges of a deep violet colour; and rendered coriaceous and greyish in

nitrous acid. But these facts do not much illustrate its organization. We find, lastly, that disease produces in its structure changes as numerous as they are difficult of explanation.

The liver is covered by two membranes, a serous and a cellular one, which are very differently arranged.

The external is formed of peritoneum, and covers the whole surface, except the posterior edge, in the situation of the coronary ligament, the excavation for the inferior vena cava, that for the gall-bladder, and the two fissures of the inferior surface. It resembles the peritoneum in general; is smooth and polished on the external surface, and connected very closely by the internal to the proper membrane of the liver, except in the situations already specified.

The other membrane, called by Soemmerring *membrana cellulosa hepatis*, has been most minutely described by the French anatomist, who assign the discovery of it to M. Laennec. Boyer describes it as covering the external surface of the organ, and moreover reflected over the vessels that enter it. Its internal surface corresponds to the tissue of the liver, to which it adheres very closely. It sends sheaths over the vessels; the most conspicuous of these is the capsula Glissoni, already described; but the hepatic vessels have one closely connected to them and to the surrounding substance of the liver, and the umbilical vein in the fœtus is furnished with a similar covering. This proper membrane of the liver is thin, transparent, and of a slightly yellow tint. It is stronger than the peritoneum; hardly admits of extension, and exhibits nothing fibrous in its texture. It may be best shown in the situations where it is not covered by peritoneum: by making an incision, and introducing the handle of a scalpel, it may be easily separated from the substance of the organ.

If the hepatic artery be injected, in a healthy liver, with any fluid kind of injection, as size coloured with vermilion, no point can be discerned in the whole organ, more particularly if the microscope be employed, in which branches of this vessel are not visible. The same observation may be made concerning the vena portarum, the hepatic veins, and the hepatic duct. If the injection be pushed farther, it will pass out of one of these vessels into the others; that is, it will pass from the hepatic artery into the vein of the same name, into the vena portarum, and into the biliary duct; or, *vice versa*, from either of these into the artery, &c. Injections do not pass from the artery into the absorbents, unless when there has been an effusion into the substance of the organ. It is said that the absorbents have been filled with liquors thrown into the vena portarum; and that the same circumstance readily takes place where mercury is introduced into the hepatic duct.

These facts concur with the result of the most careful inspection, aided even by the microscope, in proving that there is an uninterrupted passage from one order of vessels into the other, and nothing of a cellular or vesicular nature interposed between them.

Of the apparatus connected with the excretion of the bile.—The tube, which we have already described, as being formed by the union of all the excretory canals in the liver, under the name of the hepatic duct, passes from the great notch of the liver towards the left, being at the same time inclined slightly downwards and forwards, and is continued to the duodenum, in which it opens. It runs between the two laminae of the little omentum, surrounded by fat and cellular tissue, which is generally dyed of a yellow colour by the transudation of the bile. It lies on the anterior edge of this omentum, in front and rather to the right of the vena portarum, with which it is extensively in contact, and to the right of the

hepatic artery. Its size is about that of a large writing quill, its figure cylindrical, and its length from four to six inches. At about an inch or an inch and a half from the liver, we observe in it the simple round opening of the cystic duct. From this part to its termination it generally goes by the name of ductus communis choledochus; but the distinction is quite an artificial one. When it arrives near the duodenum, it becomes covered by the pancreas, which adheres closely to it, and advances along the posterior and inferior portion of the second flexure of the duodenum. It penetrates the muscular coat and that intestine, and receives the termination of the pancreatic duct. Having passed obliquely between the muscular and mucous coats, for the space of an inch nearly, it penetrates the latter, and opens into the intestine by a small orifice on one of its folds. The mucous coat of the latter, and the internal surface of the duct, are here continuous. When we examine the opening of the canal, we see a small eminence, nearly of the size of a pea, rounded, rather oblong, and divided in the middle; there is no valve, nor any muscular fibres arranged like a sphincter. The oblique course of the canal between the intestinal coats prevents the passage of the contents of the intestine into the duct, even when the intestine is the most fully distended. The duct is compressed whenever the gut is filled, and more powerfully in proportion as the distention is greater. If the duodenum be inflated, and the duct cut through, no air escapes. Ordinarily, too, we cannot doubt that the particular sensibility of the canal enables it to reject matters that are extraneous to it.

Sometimes this duct does not receive the pancreatic. Observations are recorded, in which it is said to have opened into the stomach, and close to the pylorus; but their correctness is doubtful.

The cystic duct, of which we have mentioned the opening into the hepatic, is a short canal, leading from the latter tube into the gall-bladder, and conveying into that receptacle a portion of the bile, before it goes to the duodenum.

The gall-bladder.—This bag does not exist in several genera of the mammalia; it has sometimes, but very rarely, been deficient in the human subject, without causing any sensible derangement of functions. Sometimes also there have been two gall-bladders.

It is placed obliquely, under the front of the great lobe of the liver, in the excavation already described, above the colon and duodenum, to the right of the horizontal fissure and the lobulus quadratus, and in front of the right end of the transverse notch. Its most usual figure is pyriform; sometimes it is rather oval, or cylindrical. We remark in it an external and an internal surface, an anterior extremity called the fundus, a posterior named the neck, and a middle portion or body. The fundus, or large extremity of the gall-bladder, is directed forwards, a little to the right and downwards, and the small end backwards, to the left and upwards. But the direction varies considerably according to the attitude of the body. In the supine posture the fundus is higher than the neck; the contrary is the case in lying on the right side.

The external surface of the gall-bladder corresponds above to the excavation in the right lobe of the liver; this part has been called the hepatic surface. Here it is not covered by peritoneum, but adheres immediately to the proper membrane of the liver, by means of a copious cellular substance, containing numerous blood-vessels. Sometimes it has been connected to the liver by a small kind of mesentery, and covered universally by peritoneum. The inferior part is smooth, covered by peritoneum, and contiguous to the colon

and first portion of the duodenum; it is called the loose or abdominal surface.

The anterior extremity, or fundus, turned forwards, downwards and to the right, is rounded, smooth, and covered partially or entirely by peritoneum. It corresponds to an excavation in the anterior edge of the liver, and protrudes more or less beyond this according to the quantity of bile it contains. When it is empty, its fundus does not extend beyond this edge; but, in the distended state, it projects from the liver, and is applied against the abdominal parietes, below the middle of the cartilage of the second false rib.

The neck, or posterior extremity, which is directed rather upwards and to the left, is bent upon itself, the convexity of the curve looking upwards, and the concavity downwards. It is terminated by the cystic duct, which, after a course of about an inch and a half, unites with the hepatic duct at a very acute angle. The internal surface of the gall-bladder presents a deep yellow or greenish tint, according to the colour of the bile; indeed, all this excretory apparatus is tinged after death in the same manner, but not so deeply as the surface of the gall-bladder. This effect takes place very quickly after death: when the coats of the parts, that immediately contain the bile, are coloured, the continuance of the transudation affects all the neighbouring organs to a greater or less degree. This internal surface of the gall-bladder is extremely irregular: it is universally covered with rising lines, decussating each other, and intercepting small arcuæ of various figures. These are again covered by other more minute lines, which divide the surface into very small spaces. Similar rising lines, but more elevated, are found towards the neck of the gall-bladder, and throughout the cystic duct. The whole surface of these parts, in consequence of this structure, exhibits a very beautiful rugous and cellular appearance. Besides these rugæ of the internal coat, the neck of the gall-bladder exhibits four or five transverse semilunar folds, projecting into the cavity, and formed by duplicatures of the mucous coat.

The capacity of the gall-bladder may be estimated at about one ounce.

The cystic duct is a contracted continuation of the neck of the gall-bladder, about equal to a large crow-quill in diameter. It forms at its commencement a remarkable turn, of which the convexity is towards the liver and the concavity downward. From the gall-bladder it first ascends, then makes this turn, and afterwards passes downwards, between the laminae of the little omentum, parallel and close to the hepatic duct. After a course of about an inch and a half it opens into that duct at a very acute angle. The cystic duct has an irregular knotted appearance on its external surface, which arises from numerous semilunar folds, analogous to those at the neck of the gall-bladder, projecting into its cavity, and very much narrowing its dimensions.

Two coats, a serous and a mucous, compose the gall-bladder. The former, derived from the peritoneum, gives only a partial covering to the organ. This membrane is raised from the liver, at the circumference of the depression lodging the gall-bladder, and covers this viscous every where, except at its adhesion to the surface of the liver. It is continuous below with the superior layer of the little omentum. The peritoneal coat is connected to the mucous by a tolerably thick and uniform layer of cellular tissue, the cellular coat of some writers. Some firm and rather shining threads, mostly of a longitudinal direction, are observed in this tissue, and have been often considered of a muscular nature. The blood-vessels and absorbents form a net-work in this cellular substance, which sometimes contains a little fat. The internal

nal, mucous, or villous coat, as it is frequently called, is connected below and at the sides to the peritoneal covering; above to the proper membrane of the liver. The inner surface presents the rugæ already noticed. It is of considerable thickness, and has a kind of spongy texture. During life it is white; the tint of the bile never being communicated until after death. Several anatomists have described mucous glands and follicles in this membrane; but they cannot be satisfactorily ascertained. Soemmerring, however, describes glands near the neck as large as millet seeds. On account of the folds and rugæ of the internal surface, its extent is much increased when the cellular substance is removed from the outside. After a successful injection of the blood-vessels, this coat appears to consist entirely of a vascular net-work.

The artery of the gall-bladder is a branch of the hepatic; the veins join the vena portarum. The lymphatics, which are numerous and large, join those of the inferior surface of the liver. The nerves come from the hepatic plexus.

Anatomists formerly admitted the existence of vessels passing directly from the liver into the gall-bladder, under the name of hepatico-cystic ducts. Such vessels exist in birds, but they certainly do not belong to the human subject; the only connection between the liver and gall-bladder being through the medium of the hepatic and cystic ducts.

The organisation of the hepatic and cystic ducts is essentially the same. They have two coats, an external fibrous one, and a mucous or internal lining. The former is thick, dense, and strong, and composed apparently of whitish longitudinal fibres, which have nothing muscular in their appearance, and the nature of which is not well understood. The mucous coat is thin and soft, and presents in some parts the same areolated texture as on the internal surface of the gall-bladder: the whole of the cystic duct has this peculiar arrangement, and its internal membrane forms the transverse folds already mentioned. The hepatic duct, from the liver to near the point at which it enters the intestine, is smooth: it has some longitudinal folds about its middle, and is reticulated near the duodenum.

These ducts possess very great extensibility: they are sometimes dilated, by the passage of calculi, to the size of a thumb. They, as well as the gall-bladder, act on their contents by the insensible organic contractility, or tonic power. They are never seen to contract sensibly in any observations of living animals, nor do the stimuli, which excite contractions in the muscles, produce the same effect on them. Probably the passage of the food over the orifice of the duct in the duodenum is the exciting cause of their actions. Although they are not sensible in the natural state, disease develops this property in them to a remarkable degree. No pain is more acute than that produced by calculi in these ducts.

Development of the liver.—This organ is discerned in the embryo before any of the other viscera; and it is proportionally larger in the early months of conception, than at any future time. Wrisberg saw it in a fœtus of ten weeks to large, that it occupied nearly the whole abdomen. Walter says that it can be seen at twenty-two days. At these periods it appears to be not much less than half the weight of the body. This great bulk of the organ does not last through the whole of gestation; after the fourth month, it does not proceed so rapidly in its growth, although it maintains a remarkable predominance over the other viscera till the time of birth. As a general observation we may assert, that it is larger in proportion as the animal is nearer to the time of its first formation.

During fetal existence, the blood of the umbilical vein circulates through the liver, on its way to the heart: but the whole of this blood is sent to the left lobe. (See the description of the umbilical vessels in the article EMBRYO, and the article CIRCULATION.) Hence that lobe is quite as large, if not larger, than the right. From this great bulk of the organ, as well as from the breadth of the basis of the chest, and the small concavity of the diaphragm, the relations of the liver to the surrounding parts are very different from what we observe in the adult. It not only fills both hypochondria and the epigastric region, but descends below the ribs, as far as the umbilicus, and fills half the abdomen: It is placed at this time more perpendicularly in the body, so that the convex and concave surfaces, which are superior and inferior in the adult, are nearly anterior and posterior in the fœtus. The anterior surface is extensively in contact with the abdominal parietes: the posterior covers the stomach, spleen, and even omentum. Its tissue at this time is soft and spongy, and contains a large quantity of blood: the latter circumstance gives to the organ a darker colour than it has in the adult.

We are entirely ignorant of the functions performed by the liver during fetal existence, of the relation between its size and any of the processes of the animal economy, and whether any changes are produced in the blood as it passes through the organ.

The excretory part of the hepatic system is not proportioned in its development to the size of the liver in the fœtus: for the latter circumstance is connected with the circulation, and not with the biliary secretion. The internal surface of the gall-bladder is at first smooth, and does not exhibit the areolated structure until the latter months of gestation. According to different authors this bag contains no bile, but merely a reddish mucus, until the 4th, 5th, or 6th month: its fundus is completely concealed behind the edge of the liver. At the time of birth it is always full of bile; but the fluid is still reddish and mucous, and possesses but little taste.

The sudden revolution that occurs in the circulating system at birth, produces a remarkable change in the liver. The interception of the blood, which was conveyed to the organ by the umbilical vein, is followed by a very marked reduction in its size affecting particularly the left lobe. The tissue of the organ is rendered more dense, and its colour acquires a brighter red tint, or becomes pale. After a certain time the organ participates in the progress of the other parts of the body. The excretory apparatus undergoes no remarkable change: it is not so readily tinged with bile, as at a more advanced age, probably from some change in the nature and properties of that fluid. In the old subject the organ sometimes is reduced in size, and frequently becomes more soft. On the whole, however, after the changes consequent on birth have been completely effected, and the liver has acquired its permanent relation to the other organs, very little change takes place in it.

The secretion and course of the bile.—That this fluid is separated in the liver, and conveyed from that organ by the hepatic duct, are points so clear, that they do not require any express proof. From which order of vessels in the liver this secretion takes place, is a question not so easily answered. Physiologists have generally ascribed this office to the vena portarum, and have considered the hepatic artery to be the nutrient vessel of the organ, as the bronchial arteries are of the lungs. They give the following reasons for this opinion. 1. The excretory duct is larger than the artery, a circumstance which does not occur in any other gland: its size how-

ever

ever is suitable to that of the vena portarum. 2. The agreement of the properties of the bile, particularly its thick oily nature, acrid taste, and dark colour, with the supposed peculiar nature of the blood returned by the vena portarum. This blood, it is said, is brought from very warm and moist parts, loaded with fatty matter from the omentum mesentericum, &c. and with alkaline and acrimonious particles from the intestines, particularly the large ones. Its supposed stagnation in the cells of the spleen has been conceived to impart to it some further peculiar properties, favourable to the formation of the bile. 3. Experiments on living animals, in which the secretion has been stopped by tying the vena portarum, and not interrupted by tying the hepatic artery. 4. The peculiar distribution of the vein, after the manner of an artery, in the liver, combined with the particular qualities of the blood circulating in it. 5. The artery is larger in size in the fœtus, in proportion to the greater bulk of the organ, although the secretion of bile is very small in quantity at a time when digestion has not begun.

As a proof that bile may be secreted from arterial blood a fact may be adduced, that occurred to Mr. Abernethy, and is recorded in the Philosophical Transactions. In a well-formed and nourished child, whose gall-bladder contained bile, the vena portarum terminated in the inferior vena cava near the renal veins.

There are several other considerations tending to weaken our confidence in the received opinion. Much reliance cannot be placed on the relative diameters of the artery and duct: if the latter be too large for the former, it must be regarded as too small in proportion to the vena portarum. According to Bichat there is the same relation between them as between the renal artery and ureter.

We know of no comparative analysis of the blood, contained in the vena portarum and the hepatic artery, that warrants us in ascribing to the former qualities particularly suited to the secretion of bile. Certainly we do not see in it those properties which are said to characterise it: we do not discover oily particles in it, and we believe the supposition of its imbibing any thing from the excrement to be perfectly gratuitous. Indeed Haller expressly acknowledges that the properties, which the blood of the vena portarum may necessarily acquire in its circulation, cannot be discovered by chemical analysis. Why is venous blood so particularly suited to the secretion of an oily fluid? are not fat, the medulla of bones, and cerumen formed from materials conveyed in the arteries? That any thing acquired by the blood in the spleen cannot be essential, is proved by the fact, that extirpation of that organ does not injure the hepatic functions. We do not understand clearly how the retarded motion of the blood in this vein (if in reality it be retarded) assists the formation of bile? How happens it that slowness of motion is more favourable to this than to any other secretion? We cannot reasonably apply inferences drawn from what takes place in an animal after such a serious injury as the ligation of the vena portarum or hepatic artery, to the natural functions of the organ. How long did the animals live after these experiments? and in what way were the facts of the secretion or non-secretion of the bile ascertained? "These different reflections," says Bichat, "may convince us, that our proofs are not as yet sufficient to decide whether the bile is secreted from arterial or from the abdominal system of venous blood. I do not attribute the function to one rather than to the other: but merely endeavour to shew that a fresh examination of the question is necessary, and to prove by this example that the most generally received physiological opinions, such as seem to be placed beyond all doubt by the concurring assent of the most celebrated men, often rest on very uncertain foundations. We are yet far

from the time when this science shall consist only of a series of facts rigorously deduced one from the other." *Anatomie Generale*, tom. i. p. 457.

The great size of the liver, the number and magnitude of the parts which compose its complicated vascular machinery, its enormous magnitude in the early stages of fetal existence, and its especial connection with the circulating organs at that period, all lead us to conclude that it answers some other purpose in the economy besides the secretion of the bile. This probability, and the reasons on which it is grounded, are so well stated by Bichat, in his *Anatomie Generale*, that we shall avail ourselves of his labours on this point.

"From serving as the point of termination for the abdominal system of black blood, as the lungs do for the general system of the same description, the liver derives a degree of importance, which does not belong to any other secretory organ. The disproportion between the size of the organ and the quantity of fluid it secretes, has led some authors to suspect that the organ must have a further office: and this suspicion seems to be almost a certainty. Compare its excretory tubes and reservoir to the analogous parts in the kidneys, the salivary glands, the pancreas: you will find them inferior to the first, and hardly superior in size to the others. Yet the mass of the liver at least equals all the other glands in the body put together. This great size of the organ contrasts remarkably with the small quantity of its secretion: calculate how much is consumed in colouring the feces, open the intestines to see how much they contain at different times, and you will be convinced that the quantity of the bile is much less than that of the urine, not to mention the other secreted fluids, such as the saliva, pancreatic liquor, semen, mucous fluids, &c.

"We are altogether ignorant what the other use of the bile may be. Probably it is connected with the abdominal system of black blood. The following considerations prove that it must be a very important one. The organ exists in almost all classes of animals, even where some other important viscera are very imperfect. Many of the passions affect it: some of them have an exclusive effect on it. It performs in disease as prominent a part as any of the important viscera of the economy. In hypochondria, melancholia, &c. its influence is very considerable. We know how easily its functions are disturbed. If it be unconnected with many affections called bilious, and which have their seat in the stomach, it is certainly essentially concerned in the greater part. The yellowish tint of the face in many of these affections must be produced by the same cause, which, in a higher degree, produces jaundice. The affections of this organ, observed after death, are more numerous than those of any similar part. It is a matter of common observation, that this organ has a great influence on the temperament. Its predominance communicates to the external habit of the body, to the functions, to the passions, even to the character, a peculiar tint, which was observed by the ancients, and the reality of which has been confirmed by modern observation. Nothing like this can be observed of the other glands. With the heart and brain this is the part first formed: its development precedes that of all other organs, and is incomparably superior to that of other glands. It has been latterly supposed that the liver assists the lungs in removing from the blood hydrogen and carbon. I know not on what proofs this assertion may rest: but the colour of the fluid is certainly not affected by its passage through the liver: neither is it altered in consistence, nor in any way that can be recognized by the touch."

Course of the bile.—There are two kinds of this fluid, differing

differing considerably in their properties, and distinguished by the names of hepatic and cystic. The former, which is contained in the hepatic duct, and in the branches of that tube distributed through the liver, approaches in fluidity to water, is of a bright orange colour, and not bitter: so far, indeed, is it from containing any qualities offensive to the taste, that the livers of animals, which must always contain much of it, are commonly employed for food. The latter, or bile of the gall bladder, is a thick ropy fluid, of a deep orange brown, or even green tint, and most intensely bitter. Both these kinds are secreted in the liver, and originally are not different. The gall-bladder receives what it contains through the cystic duct, and produces in it the changes just described while it remains in this reservoir. A copious mucous secretion takes place from its lining, and the aqueous parts of the bile are removed by the numerous and large absorbents of the receptacle. The cystic bile is, therefore, nothing more than hepatic bile in a concentrated state. It is easy to prove that the gall-bladder can receive bile only through the cystic duct: we have already observed, that the hepatico-cystic ducts are imaginary; we may add, that if the bladder be removed with its contents, the cystic duct tied, and pressure then applied to the part in every direction, not a particle of the fluid escapes. If the cystic duct be obstructed by a calculus, or obliterated by disease, no bile is contained in the gall-bladder, which, on the contrary, is filled with a colourless mucus. If we evacuate the receptacle in a living animal, and tie its duct, it will be found under the same circumstances; and the cystic duct, from its opening into the hepatic to the ligature, will be distended.

The gall-bladder, from the view of its functions, does not seem to be a very important organ in the economy. Several animals, among the mammalia, do not possess it, as the horse, stag, elephant. No ill effects have been observed, where the cystic duct has been obliterated; nor where there has been a natural deficiency of the organ.

That the fluid secreted in the liver flows in part directly into the intestine, would be naturally inferred from observing the size and favourable direction of the hepatic duct for this course, and the comparatively unfavourable direction, tortuous course, and small diameter of the passage leading into the gall-bladder. These circumstances, indeed, would lead us to expect that the bile would enter the gall-bladder in very sparing quantity. If an animal be opened, when the intestinal functions are not going on, the hepatic duct, and the ductus choledochus, contain hepatic bile; the surface of the duodenum and jejunum is tinged with the same kind of fluid; and the gall-bladder is distended with cystic bile, of which the properties are the more strongly marked in proportion to the length of the previous abstinence. While the stomach is exerting its action on the food, the same appearances are exhibited. When the aliment has passed into the duodenum, the ductus choledochus contains dark-coloured cystic bile, and the gall-bladder is less full. At the end of digestion, and a little after, the hepatic and common ducts, and the gall-bladder, all contain a light-coloured bile; which is observed also in the duodenum. The gall-bladder is flaccid. These observations are deduced from experiments made by Bichat, and recorded in his *Anatomic Generale*, p. 459. "They were repeated," says he, "a great number of times, and shew clearly, that the secretion goes on to a certain amount at all times, but that this quantity is increased during digestion. The bile furnished when the action of the intestine is not going on, is divided between the intestine, which is always coloured by it, and the gall-bladder, which retains it without pouring out any through the cystic duct: while it is thus retained, it acquires its acrid character, deep tint, and

the properties which seem to be required for the purposes of the digestion that is to ensue. When the food, after undergoing the action of the stomach, enters the duodenum, all the hepatic bile flows into the intestine, and even in greater quantity than before. The gall-bladder at the same time pours out its contents. When the action of the intestine is concluded, the quantity of fluid secreted by the liver is diminished, and it flows partly into the duodenum, and partly into the gall-bladder, where it is then seen in small quantity, and of a bright colour, because there has not yet been sufficient time for it to be collected more abundantly, nor to acquire a deeper colour." Bichat is of opinion that the stomach always contains a certain quantity of bile. "In its empty state," says he, "we always find in it more or less mucous fluid, sometimes mixed with small globules of hydrogen gas, and almost always tinged of a yellowish colour by bile, which has entered through the pylorus. Haller says, that this reflux does not always take place; but it is constant, according to Morgagni. I have opened no dog where it could not be manifestly discerned in the empty stomach, particularly when it had been long empty. The bodies of persons, who die of disease, are not fit for deciding this question, as the disease may alter the course, nature, and colour of the bile. When the stomach was full, I could not sometimes ascertain the presence of bile: in other instances I observed a yellowish fluid between the alimentary mass and the coats of the stomach. The bile entering the stomach has always appeared to me, from its colour, to be hepatic; I have never seen that dark fluid which is contained in the gall-bladder, and which is vomited in some diseases. This accords with the observation made above, that hepatic bile only enters the duodenum during abstinence. It is evident that the passage of the food from the stomach, at the commencement of intestinal digestion, at which time cystic bile certainly flows into the duodenum, must prevent that bile from going through the pylorus."

We have mentioned, in the article *DIGESTION*, the effects produced on the contents of the intestine by the admixture of the biliary fluid. On this subject, indeed, the amount of our knowledge is very trifling: that the presence of the fluid is essential to the right performance of the intestinal functions, and that the colour of the feces is derived from its admixture, are obvious facts, and they include nearly all that is hitherto proved.

The chemical composition of the fluid is considered under the article *BILE*.

The sympathies of the liver, with other organs, are very numerous and important; and render its physiology very interesting to the physician. It is connected primarily or secondarily, as cause or effect, with various disorders of the head, chest, and abdomen.

LIVER, Chromatic diseases of the, in Medicine.—Having already treated of the acute inflammatory affections of the liver (see *HEPATITIS*), and of the various obstructions to the exit of the bile into the intestines, which give rise to *Jaundice* (see that article); it remains for us to describe, in this place, the other morbid changes to which this organ is liable, and which are of a slow or *chronic* kind. These are, principally, the slow inflammation of the liver, or chronic hepatitis, as it has been called; induration, or a ferruginous state of the organ; softness of it; enlargement, or diminution of its bulk; the formation of tubercles in it; adhesions of it to the contiguous parts, &c. The formation of those vesicular cysts, which are denominated *hydatids*, in the liver, has been already discussed under the general head. See *HYDATIDS*.

The chronic inflammation of the liver is a disease, which is

is more common in this country than the acute; and is often so insidious in its progress, and accompanied by so few symptoms of serious indisposition, as to have advanced to a complete suppuration, before its existence was suspected. In some measure, indeed, a similar observation applies to all the chronic derangements of the substance of the liver, which often excite no alarm, by the symptoms which might be expected to accompany them, until they are fully formed. The slight indisposition that occurs is attributed to indigestion, flatulence, or some other affection of the stomach; the pain of which the patient occasionally complains is falsely referred to that organ; and its continuance is so short, and the degree of it frequently so inconsiderable, as to demand but a slight attention. The relief obtained by eructation and the discharge of air also tends to confirm the opinion, that the seat of the disease is in the stomach: but this relief may be explained on the principle of removing the distention of the stomach, and so taking off the pressure of this organ from the liver.

Where this slow inflammation and gradual obstruction is going on in the liver, the patient is subject to occasional pain in the right hypochondrium, extending to the *scapula*, or to the top of the shoulder, a quick pulse, an increase of heat, alternating with chilly sensations, difficult breathing on quick motion, some difficulty of lying on the left side, flatulence, indigestion, acidity, costiveness; and, together with a gradual diminution of strength and flesh, he has a pale or fallow complexion. The complexion, indeed, of a person affected with chronic obstruction in the liver, although often not wearing the appearance of jaundice, yet has frequently a peculiar sallowness, or a dirty-greenish hue, which Dr. Darwin, from its resemblance to the colour of a full-grown silk-worm, has aptly enough denominated *bombycinus*. The extent and duration of pains, Dr. Saunders observes, arising from disease of the liver, are so various, as frequently to deceive both the physician and patient; they extend to the shoulder, *scapula*, muscles of the neck, along the arm, even to the joints of the wrist. Every change of posture either relieves an old pain, or induces a new one, as does the mere bending of the body in any direction, or even extending the arms. The pains are greater in a supine, than in an erect posture.

These symptoms, and some others which make their appearance in the more advanced stages, are sufficient to point out the existence of chronic disease in the liver: but it is to be regretted, that they are not peculiar to chronic inflammation of the organ; and that the varieties of hepatic obstruction are not distinguished from each other by any particular combinations of symptoms; for it must be obvious, that the same remedies cannot be administered with advantage in diseases, which are essentially so different in their nature, as those which we are about to describe.

The term *schirrus*, when applied to the liver, has been employed in two acceptations, or at least to denote two different stages of a disease, if not two different diseases: namely, an induration of the substance of the liver generally, and the formation of the common tubercle in it; the former of which is, in the opinion of Dr. Baillie, the first step towards the latter. When an indurated liver is examined by dissection, no peculiar alteration of structure is observed; only the substance of the gland is found uniformly of a more compact and solid consistence, or less soft and porous, it is somewhat diminished in bulk, and the lower edge is bent a little inwards; the colour, too, is somewhat paler, in consequence of a diminished secretion of the bile, or of a less free admission of blood into the substance of the organ. Upon the surface of such a liver, Dr. Baillie remarks,

"there is not uncommonly a thready appearance of membrane, disposed somewhat in a radiated form. This, I believe to be the first step in the progress towards the formation of the common tuberculated liver. I have sometimes seen small tubercles formed upon a part of the surface of such a liver, which were exactly of the common sort, &c. This hardened state of the liver is sometimes accompanied with a beginning ascites, and sometimes is without it." Loc. cit.

Dr. Saunders observes, that in these cases of induration of the liver, there is, together with a diminution of bulk, also some degree of loss of weight. This, however, he believes, occurs only in the latter stages of the disease, when it is usually seen by the anatomist. For, considering that the disease is commonly the result of one of the two following causes, *viz.* a long residence in a hot climate, or the immoderate use of spirituous liquors, both of which tend to produce an over-excitement of the circulation, and a hurried secretion, he deems it most probable, nay he is persuaded, that in the more early stages of *schirrosis*, the liver is not only not sensibly diminished in bulk, but that there is at that period an increase both of bulk and weight, which is followed by a gradual diminution of both. "To produce an increased secretion of bile," he argues, "it is plain that there must be an increased action of the branches of the vena portarum, and an acceleration of fluids through those branches: hence a condition of vessels is induced, approaching in some respects to that of inflammation; with this difference, that it is an inflammation in which the vein, or secreting vessel, is more concerned, than the artery or nutrient vessel. The effect of this action, especially when protracted for a considerable time, must necessarily be that of inducing an alteration in the structure of the part: an alteration similar to what obtains in other organs, labouring under indolent and chronic inflammation. This change of structure, from its solidity and compactness, seems to depend on the effusion of the coagulable lymph into the parenchymatous substance of the liver; with this peculiarity, that while it is, in active inflammations, deposited by arteries, it is, in the chronic kind, effused by the veins, &c." This effusion, however, he adds, impedes the secretion of bile; and, where a part has lost the power of performing its functions, the absorbents often become active, and remove it: whence the diminution of weight as the disease advances. (Saunders's Treatise on Structure and Dis. of the Liver, 3d edit. p. 282, et seq.) At all events, the view of the disease, which ascribes the effusion of the interstitial matter, and the consequent induration, to a previous excitement of the vessels and hurried secretion, accord both with the general laws of the animal economy, and with the known ordinary causes of this disease.

With respect to the other modification of *schirrous* liver, which is one of the most common of its diseases, we cannot do better than repeat Dr. Baillie's accurate description. "This disease," he says, "is hardly ever met with in a very young person, but frequently takes place in persons of middle or advanced age: it is likewise more common in men than in women. This seems to depend upon the habit of drinking being more common in the one sex than in the other; for this disease is most frequently found in hard drinkers, although we cannot see any necessary connection between that mode of life and this particular disease in the liver. It happens, however, very commonly, that we can see little connection between cause and effect in changes which are going on in every other part of the body.

"The tubercles, which are formed in this disease, occupy generally the whole mass of the liver, are placed very

near each other, and are of a rounded shape. They give an appearance every where of irregularity to its surface. When cut into, they are found to consist of a brownish or yellowish-white solid matter. They are sometimes of a very small size, so as not to be larger than the heads of large pins; but most frequently they are as large as small hazel nuts, and many of them are sometimes larger. When the liver is thus tuberculated, it feels much harder to the touch than natural, and not uncommonly its lower edge is bent a little forwards. Its size, however, is generally not larger than in a healthy state, and I think it is often smaller. If a section of the liver be made in this state, its vessels seem to have a smaller diameter than they have naturally. It very frequently happens that in this state the liver is of a yellow colour, arising from the bile accumulated in its substance; and there is also water in the cavity of the abdomen, which is yellow, from the mixture of bile. The gall-bladder is generally much contracted, and of a white colour, from its being empty. The bile, from the pressure of the hard liver upon the *pori bilarii*, does not reach the *ductus hepaticus*, and therefore cannot pass into the gall-bladder. The colour of the skin in such cases is jaundiced, and it remains permanently so, as it depends on a state of liver not liable to change. This is the common appearance of what is generally called a scirrhus liver; but it bears only a remote resemblance to *scirrhus*, as it shews itself in other parts of the body. I should therefore be disposed to consider it as a peculiar disease affecting this *viscus*." Morbid An. chap ix.

This account of the state of the indurated and tuberculated liver renders it unnecessary to explain, at any length, the origin of the dropsy, jaundice, &c. which accompany these diseases, when inveterate. It must be obvious to those who understand the structure of the parts, that if some bile is secreted in the liver, but, from the compressed state of the ducts, it cannot pass into the intestines, it will be absorbed into the circulating blood, and produce jaundice. (See JAUNDICE.) And dropsy will ensue, in consequence of the impermeability of many of the blood-vessels of the liver, which are compressed by the surrounding tubercles; whence, as in all cases of such obstruction to the circulation, the thinner parts of the blood will exude from the exhalant extremities of the over-distended vessels behind. (See DROPSY, *causes of*.) From the same obstruction, and the over-dilatation of the venous system, these vessels are liable to give way; whence hemorrhages, or discharges of dark blood, are liable to occur, under such morbid states of the liver from the stomach, intestines, nose, and other internal passages; but especially from the two former, since the blood which circulates through them, as well as through the *spleen*, *pancreas*, and *omentum*, must pass through the liver to reach the heart; the circulation, therefore, must be particularly impeded in the organs just mentioned, when that of the liver is obstructed; and the blood will force its way through other passages, if the vessels are not strong enough to resist any extraordinary distending force.

The liver is liable to be affected with other varieties of tubercle, of a larger size than those above described; Dr. Baillie has mentioned three varieties of these, which he calls the large white tubercle, soft brown tubercle, and serous tubercle. The first of these, which is by no means so frequently met with as the common tubercle, resembles more nearly the ordinary appearance of scirrhus in other parts of the body. These tubercles are hard whitish masses, of a lobular form, and firm opaque substance, often as large as a chestnut, and sometimes much larger, or on the other hand, considerably smaller. "They

are to be found near the surface of the liver," Dr. Baillie observes, "in greater number, than near the middle of its substance: two or three frequently lie contiguous to each other, with a considerable portion of the liver, in a healthy state, interposed between them and a cluster of similar tubercles. The liver in this disease is frequently a good deal enlarged beyond its natural size." Dr. Baillie adds, that "these tubercles appear to be first formed round the blood-vessels of the liver, as is seen in making sections of a liver in this state. While the liver is under such circumstances of disease, there is sometimes water in the cavity of the abdomen, and sometimes none; the liver is sometimes tinged in its colour, from the accumulation of bile, and sometimes the colour of its substance, between the tubercles, is perfectly natural." (Loc. cit.) The two other species of tubercle are very rare; the one consists of a smooth, soft, brownish matter, the nature of which is not thoroughly known; the other bears a strong resemblance to the tubercle of the lungs. See CONSUMPTION.

There are no peculiar symptoms, by which the existence of these different tubercles can be discriminated in the living body. When the parietes of the abdomen are thin, and there is little dropsy, and especially when the liver is enlarged, the tubercles can sometimes be distinctly felt by the fingers, upon an attentive examination, along the lower edge of the viscus. Dr. Baillie correctly states, that the large white tubercle is not so often attended with jaundice and ascites as the common tubercle. We witnessed the exemplification of these observations, in a striking instance, some years ago; in which a woman, addicted to spirit-drinking, had been affected with the large tubercle of the liver for several years, but had complained only of loss of appetite, and occasional sickness and pains in the side, had been pregnant and brought forth twins, and never had any appearance of dropsy to the last, nor of a jaundiced complexion, until within eight days of her death. Yet in this person, the liver was not only found about three times its natural bulk, (filling half the cavity of the belly, and being distinctly felt, before death, extending down the *umbilicus*, and thence to the spine of the *pelvis*;) but appeared, on making a section, to consist of a mere mass of tubercles, with some loose interstitial matter, but without any semblance of the natural substance of the viscus. The section presented an appearance not unlike the pudding-stone of mineralogists. It would seem that, from the luxury of the intervening substance between the tubercles, the circulation through the branches of the *vena portæ* was not materially impeded; and hence no dropsical effusion took place from the vessels of the peritoneal viscera. The patient was confined to bed only eight days, and was apparently cut off by an incessant agonising pain in the diseased organ, which first induced delirium, and afterwards wore out the powers of life.

The liver is not unusually found softer and much more flaccid in its substance than natural, without any other appearance of disease. It feels, in such instances, nearly as soft as the spleen, and is commonly of a leaden colour. This state of liver is seldom, if ever, found in young persons; most commonly in persons advanced in life. Some other rare morbid changes have also been seen in the liver; such as the conversion of part of its coats into cartilage, and the formation of cartilaginous cysts in its substance, containing an earthy matter of a soft smooth quality, and brownish-white colour.

It is not unusual, on dissection, to see adhesions formed between the liver and the contiguous parts, which are the consequence of a previous inflammation in the membrane covering

covering the liver. These adhesions are formed from the coagulable lymph of the blood, which undergoes a gradual process of elongation from the motion of the parts, so as to produce little inconvenience, and in some circumstances of disease much advantage. They consist very commonly of a thin transparent membrane, which joins the surface of the liver to the neighbouring parts. This junction may either be general over one extended surface of the liver, or it may consist of a number of processes of adhesion: the adhesion is sometimes by a membrane of considerable length; and sometimes it is very close, the surface of the liver being immediately applied to the neighbouring parts. These adhesions are most commonly found on the anterior surface of the liver, by which it is joined to the *peritoneum* lining the muscles at the upper part of the cavity of the abdomen. When an abscess is formed in the substance of the liver, and points externally, these adhesions are of great use in preventing the pus from escaping into the general cavity of the abdomen. Adhesions are also frequently found connecting the posterior surface of the liver to the stomach and the *duodenum*: and these may also be useful in abscesses of the liver, near its posterior surface, by preventing the matter from passing into the general cavity of the abdomen, and conducting it either into the stomach, or the upper part of the intestinal canal. See HEPATITIS.

Professor Portal of Paris, an able and sedulous cultivator of morbid anatomy and medicine, has pointed out some difficulties in forming an accurate diagnosis, between diseases of the liver and of some of the neighbouring organs, especially of the lungs. On the one hand, he observes, that obstructions and congestions in the right lobe of the lungs, and the right cavity of the chest, sometimes occasion such an alteration in the situation of the liver, by pressing down the diaphragm, as to produce a suspicion of disease in it, by occasioning the appearance of a tumour in the right hypochondrium. He relates a case of this sort, in which he was deceived, by this apparent tumour, in a patient who died of pulmonary consumption, where little or no expectoration took place: and he cautions practitioners not to be misled by such an appearance, which is common in all congestions of the chest. He affirms, too, that a degree of jaundice is occasionally produced, where the bile has free passage into the intestines, but is there detained, in consequence of mechanical impediments, as *volvulus*, strangulated *hernia*, accumulations of hardened faeces, &c. when it is taken up by the lacteals, and enters the blood-vessels. On the other hand, he remarks, if we sometimes attribute diseases to the liver, which have their seat elsewhere, there are other maladies, actually seated in the liver, which are frequently ascribed to other organs. Thus the contiguous *viscera*, such as the right kidney, the diaphragm, the lungs, the stomach, and the colon, are sometimes supposed to be affected with disease, which is seated exclusively in the liver. Many examples of this are to be found in the writings of Morgagni and Lieutaud. Mr. Portal relates two cases of severe and continued vomiting, connected with diseased liver, the first of which proved fatal; and the other was cured, in consequence of the lesson taught by the previous dissection. An enlargement of the liver was felt externally, with great tenderness in the epigastrium. See *Mem. de l'Acad. des Sciences*, Ann. 1777; or *Mem. sur plusieurs Maladies*, par Ant. Portal, tom. i. p. 228.

Where there is evidence of the existence of a considerable degree of disease in the liver, the prognostic must be always unfavourable, on the whole: for, in the first place, it is extremely difficult to ascertain the exact state of the organ; and, secondly, if we actually knew it, the most judicious

application of the most powerful remedies would be unequal sometimes to remove the disease. The most favourable symptoms are, an improvement in the complexion, the strength remaining unimpaired by the action of the medicines, and a return of appetite. Dr. Pemberton thinks that if the patient decidedly gains bulk in the solids of the body, you may safely pronounce that he will recover. The most unfavourable symptoms are, the colour of the skin remaining the same, or becoming more fallow, the general strength being much diminished, the abdomen beginning to swell, and the patient losing bulk in the upper extremities, while the lower become more enlarged. Pemberton on Dis. of the Abdom. Viscera, p. 43.

When the liver is so far diseased as to have become scirrhus, tubercular, or in any other way much altered in its structure, it must be obvious that medicine cannot effect any essential change. The treatment, therefore, which is to be recommended must be considered as applying to that stage of disease, which precedes any extensive organic alteration. It is not improbable, as Dr. Saunders suggests, that the original mischief is commonly in the stomach and bowels, and that the liver becomes diseased by sympathy: for dyspeptic complaints generally precede the chronic affections of the liver; and they are induced by intemperance in eating or drinking, but particularly by the abuse of vinous and spirituous liquors, by long fasting, by a sedentary mode of life, by grief and anxiety of mind, &c. (See DYSPEPSIA.) Whatever weakens the digestive powers of the stomach, Dr. Saunders maintains, ultimately weakens also the power of the liver, and diminishes the secretion of bile. (Saunders on the Liver, p. 192.) And again, he considers the diminished secretion of bile, or its diminished protrusion into the *duodenum*, (which he ascribes to an hypothetical constriction of the bile-ducts,) as reciprocally acting upon the stomach, and weakening its tone. One proof of the existence of the supposed spasmodic constriction of the orifice of the common duct he deduces from an observation, that, in a fit of sick head-ache, if bile is brought into the stomach, and thence ejected, by the violent straining to vomit, the termination of the fit is much more speedy and complete than when this does not happen.

When the diminished or altered secretion of the bile, then, is preceded by affections of the stomach, such as loss of appetite, indigestion, and flatulent eructations, the diet of the patient should be attentively regulated, the art of cookery should be rendered merely subservient to digestion, and the preparation of healthy chyle; and the general regimen should be such as has been already recommended in disorders of the digestive organs. (See INDIGESTION.) The quantity of food taken at one time should be moderate, and water should be the only liquid drunk with the meals, as more effectually promoting digestion than fermented liquors of any kind. All raw or unboiled vegetables should be avoided; but ripe fruits may be moderately taken, and almost all boiled vegetables admitted. Animal food should be well boiled, or moderately roasted, and taken with its own gravy. Pye-crust, every thing fried, butter rendered rancid by being melted, &c. should be cautiously avoided. The patient should use regular and moderate exercise.

It is of the highest importance, in order to keep up a due secretion of the bile, to administer a succession of gently purgative medicines. Upon this principle, the benefits arising from the waters of Cheltenham (which cannot be too highly recommended in these complaints) are obviously to be explained. Nevertheless, so far as the mere operation of these waters is concerned, no good reason can be assigned for any superior efficacy to be expected from them, rather

than from the administration of an equally active dose of the sulphate of magnesia, or other saline laxatives, dissolved in a proper quantity of water. Three drams of this salt in half a pint of fluid, as in the Seidlitz water prepared by N. Paul and Co., may be taken every morning, or every other morning, according to the strength and state of bowels of the patient. The regularity, temperance, and exercise, and likewise the absence of the anxieties of business, which contribute materially to assist the beneficial influence of those waters, when drunk at the springs, should, however, be conjoined with the employment of these substitutes at home.

In the chronic derangements of the liver, producing a diminished secretion of bile, and particularly when such affections have arisen from inflammation, mercury has been found one of the most effectual remedies. It is only, however, in the chronic state of inflammation that this remedy is administered with advantage. But the success of it, in these cases, has led perhaps to an empirical practice, of exhibiting it without sufficient discrimination between inflammations of a more indolent, and those of a more active nature, on the one hand, and between inflammation and the tuberculated state, &c. on the other. But, as Dr. Saunders remarks, to exhibit a medicine without due discrimination, is to abuse it, and at length to bring it into contempt and neglect. And this fate may perhaps await the use of mercury in complaints of the liver, if, by a blind empirical administration of it, it be incautiously employed in the *active* periods of inflammation, when, from its stimulant properties, it appears better calculated to accelerate than to retard the suppurative process. But upon this point we have enlarged, when treating of the cure of HEPATITIS; and shall now only repeat, that it is in the chronic state of inflammation alone, that the exhibition of mercury can be resorted to with benefit; for it now acts as a spur upon the vascular system of the liver, and, by its moderately stimulating effects, occasions at length a degree of action, by which the bile is properly elaborated, and health gradually restored.

That a great variety of complaints, both local and general, which have been comprehended under the terms nervous, hypochondriacal, bilious diseases, &c. originate from diminished secretion of bile, which, under such diminution in quantity, is also liable to be vitiated in quality, practitioners are again coming to admit. By observing physicians of all times, indeed, this general fact had been noticed; and upon it, a principal part of the ancient humoral pathology, which ascribed those diseases to the prevalence of *bile* and *black bile*, was founded. We cannot now, with all the additional lights afforded by a better cultivation of anatomy, physiology, and the collateral sciences, lay down a perfect theory of the subject. A learned and ingenious physician to Guy's Hospital has long investigated the point, and has long been pledged to lay the result of his practical inquiries before the public. They have not, however, yet appeared. But from the publication of a small pamphlet, as the precursor of his volume, it would appear that he has satisfied himself, both with respect to certain means of practical discrimination, and as to the mode of operation of the mercurial remedies. It would seem, from this pamphlet, that the author considers most of these diseases as dependent on a constricted or obstructed state of the hepatic ducts, and mercury, administered in small doses, and in its milder forms, as possessing the property of "emulging" the ducts, especially when irritation about the parts is soothed by opiates: in other words, that these mercurials are, in the strict sense of the word, *abolagogues*. After having described the case of a delicate female, affected with great irregularity of bowels, termi-

nating in dysentery, and accompanied with paleness, languor, dejection of spirits, loss of appetite, quick small pulse, &c. which had been rather augmented than relieved, by repeated doses of calomel and rhubarb, alternated with opiates, and which yielded to small doses of the *pilula hydragryi*, preceded by an opiate, and followed by a dose of castor-oil;—he thus states his view of the disease, and of the *modus operandi* of these remedies. "The depressed action of the brain which anxiety occasions, produced a corresponding defect of action in the liver; whence the intestines, from not being supplied with bile in sufficient quantity, or healthy in quality, became irritated by the food passing through them in an undigested state. The purgatives, astringents and opiates, which were first employed, gave temporary relief, but left the *source* of the disorder as it was; whilst the calomel, acting merely as a simple evacuant, carried off nothing but the exilting contents of the intestines, and still farther weakened their tone. But, by allaying intestinal irritation by opiates, then relaxing the hepatic ducts by the *pil. hydragryi*, and lastly, emulging them by the aid of a mild cathartic, the order of nature was restored, and that harmony of function between these parts which is necessary to health, completely established." (See An Examination of the Prejudices commonly entertained against Mercury, &c. by James Curry, M.D., &c. 2d edit. p. 20, note. Lond. 1810.) This explanation of the alleviation of the disease is sufficiently plausible; it is, however, but an hypothesis; for the previous *constriction*, the subsequent *relaxation*, and the ultimate *emulging* of the biliary ducts, are incapable of demonstration; neither is the first assumed circumstance adequate to explain the altered quality of the bile, nor the two latter its changes to the healthy state. It is sufficient, however, if it be practically ascertained, that this mode of mercurials, preceded or combined with anodynes, and followed by gentle cathartics, is an efficient mode of treatment in these cases of diminished or vitiated secretion of bile.

In those cases of diseased liver, which have been sometimes denominated scirrhus, when, either from previous acute inflammation, or from frequent accelerated secretion of bile, during a long residence in a warm climate, the vessels of the liver have poured out, into the parenchymatous substance, so much coagulable lymph, as to render it firm and indurated,—then it is often necessary to push the use of mercury farther, so as to produce a gentle salivation, which, when kept up for a length of time, often effects a cure, by promoting absorption. In the exhibition of mercury for this purpose, a preference has been given to its introduction by friction on the skin, through the cutaneous absorbents; and the part on which the mercurial ointment has been rubbed is the right *hypochondrium*, from a notion of its efficacy being greater when applied to the vicinity of the diseased organ. But it is pretty obvious, that, except in so far as friction may serve the purpose of gentle exercise to the part, and thus assist in emulging the biliary ducts, there is no material advantage derived from this; and that it is of little importance what part is made choice of, provided the effects produced on the general system be equally strong. The knowledge derived from anatomy respecting the structure, origin, and direction of the absorbent vessels, sufficiently proves that, whether used internally, or introduced by external friction, none of the mercury can be made to pass through the liver in its way into the constitution: it cannot, therefore, act on the liver, but by being first introduced into the blood-vessels. Such parts of the body as have the finest cuticle, as in the inside of the thighs, between the fingers, in the groin, &c. which afford the best absorbing surface, should be chosen for the purpose of the friction.

On the other hand, the tuberculated state of the liver is perhaps always beyond the power of mercury to alleviate, and often it would seem even aggravated by its exhibition. Medicine may contribute greatly to relieve distressing symptoms, in such cases, but cannot be expected to change the morbid structure. Flatulence, pains in the sides, stomach, and belly, indigestion, &c. may be greatly diminished by laxatives, absorbents, gentle tonics, and occasional antispasmodics; and the digestion may be favoured by the choice of light diet, taken in moderate quantities. But it cannot be expected that the system shall be put under the stimulus of a mercurial course with impunity, much less with advantage, under such circumstances.

LIVER, *Infarctions of the*. See HEPATITIS *Infarctio*.

LIVER, in *Antiquity*, was much used in divination. See HEPATOSCOPIA.

LIVER of Antimony, in *Chemistry*, results from the detonation of antimony with an equal weight of nitre. These two matters reduced into powder are to be mixed together, and put into a large crucible. The mass is then to be kindled, and the detonation to be made. When it has detonated it is to be kept in fusion, and then cooled. When the crucible is broken, at the bottom two distinct matters are found, which may be separated from each other by the stroke of a hammer. The upper matter is a saline scoria, nearly of the same nature as the scoria of the regulus of antimony. This is a true antimonial liver of sulphur, mixed with a certain quantity of vitriolated tartar. The lower matter is heavier. It is opaque, compact, red, and brittle. This is the liver of antimony. Its colour and appearances have been supposed similar to those of the livers of animals, whence its name. It is principally composed of the metallic part of antimony, half deprived of its sulphur, and dephlogisticated by nitre. This substance is of no use in chemistry, nor in medicine, since the kermes mineral and emetic tartar have been introduced. Macquer's Chem. Dict. See ANTIMONY.

LIVER of Arsenic, is a combination of white arsenic with liquid fixed vegetable alkali, or by the humid way. The operation for making liver of arsenic is easy and simple: to strong and concentrated liquid fixed alkali, previously heated, fine powder of white arsenic must be added, till the alkali is saturated, or has lost its alkaline properties. While the alkali dissolves the arsenic, it acquires a brownish colour, and a singularly disagreeable smell; and the mixture gradually thickens into a gluey consistence. Chem. Dict. See ARSENIC.

LIVER of Sulphur is the combination of sulphur with alkaline matters: and this combination may be made either in the dry or humid way. In the dry way, or by fusion, a mixture of equal parts of fixed alkali and sulphur is put into a crucible, and quickly fused. The melted mass is then poured on a greased stone, and then the liver of sulphur congeals and acquires a brown colour. If it be required to be kept dry, it must be soon broken to pieces, and put, while it is hot, in a bottle well corked, because it readily imbibes moisture from the air. In the humid way, which is less common, concentrated liquid fixed alkali, and fine powder of sulphur, are to be boiled together, till the alkali has dissolved as much as it can: the liquor is then to be filtrated and evaporated.

Liver of sulphur is an important combination in chemistry, because it is in general a very powerful solvent of metallic matters; to all which, excepting zinc, it attaches, particularly in fusion. It seems to dissolve gold more effectually than other metals. It dissolves all vegetable coals even by the humid way: and the solution is of a green colour. Partic-

ular kinds of livers of sulphur may be formed by the combination of volatile alkali, of quick-lime, or of absorbent earths, all which attack sulphur more or less. Chem. Dict. See SULPHUR.

M. Navier has lately discovered, that the liver of sulphur, and particularly of liver of sulphur of Mars, hath the most salutary effects as an antidote against arsenic, corrosive sublimite, verdigris, and lead. Nav. Contre Poisons de l'Arsenic, &c. 1777. See LEAD.

LIVER-stone See LAPIS *Hepaticus*.

LIVER-wort, in *Botany*. See LICHEN.

LIVER-wort, *Noble*, *Hepatica*, a species of the anemone.

LIVERMORE, in *Geography*, a town of America, in Cumberland county, Maine, situated on both sides of Androscoggin river; 19 miles N.W. of Hallowell, and containing 863 inhabitants.

LIVERNON, a town of France, in the department of the Lot, and chief place of a canton, in the district of Figeac; eight miles W.N.W. of Figeac. The place contains 713, and the canton 7786 inhabitants, on a territory of 285 kilometres, in 17 communes.

LIVERPOOL, a market town, borough, and sea-port, in the county palatine of Lancaster, England. It is placed on the eastern bank of the river Mersey, which flows into the Irish sea, not far north of Liverpool. The population of this town, according to the parliamentary returns of 1800, amounted to 77,653 persons, who occupied 11,446 houses.

The etymology of the word Liverpool is much involved in obscurity, though many ingenious antiquaries have endeavoured to ascertain it. The most general opinion is, that it owes its origin to a species of bird called the *lever*, great flocks of which are said to have frequented a pool in this neighbourhood, during their wanderings from their native climes. Accordingly a bird has, from time immemorial, been the impression on the corporation seal. The early history of this town is equally as unknown as the derivation of its name. Fortunately, however, the deficiency of records concerning it cannot be felt as a great loss, as there seems little reason to suppose it was of any importance, either commercially or politically, previous to the commencement of the last century; hence it may be called a modern town.

"Yet scarce an hundred annual rounds have run,
Since first the fabric of this power begun;
His noble waves inglorious, Mersey roll'd,
Nor felt his waves by labouring art control'd.
Along his sides a few small cots were spread,
His finny brood their humble tenants fed."

Mount-Pleasant, a poem by Roscoe.

To the active, persevering, and liberal conduct of the author of these lines, Liverpool is materially indebted for its present increase of buildings, commerce, &c. and it would have reflected credit on the free burghers of the town, had they continued to elect him their member.

In the Conqueror's survey, it is stated, that all the land between the rivers Ribble and Mersey belonged to Roger de Poitiers; but there is no mention either of a town or village. Hence it may be reasonably supposed none existed at this time. A castle, however, is noticed by Camden, as having been built shortly after the conquest, the command of which was bestowed on Vivian de Molyneux, a Frenchman, in whose family it continued till the 30th year of the reign of queen Elizabeth.

Neither history nor tradition determine any thing certain, either concerning its founder or the period of its erection.

LIVERPOOL.

The tower, which forms part of a prison in Water-street, is the only building of antiquity which Liverpool can now boast of possessing. The original founder of this tower we are as ignorant of as we are of the founder of the castle. Seacombe, in his *Memoirs of the Stanley family*, is the first author who mentions it. He tells us, that it was the property of sir Thomas Latham, in the reign of Edward III., whose daughter and heirs married sir John Stanley; but says nothing of its erection. The cross which formerly stood at the corner of Pinfold lane, opposite the Flashes, has been long demolished. This tradition reports to have been placed there in commemoration of St. Patrick, who, it is said, rested in this neighbourhood on his way from England to Ireland.

The first charter in favour of Liverpool, according to Enfield, who published a history of Liverpool, was executed in the reign of Henry I., but the accuracy of this statement is extremely doubtful. It is certain, however, that in the charter granted by king John in 1203, nearly a century afterwards, this town is called a borough by prescription. Henry III. confirmed the privileges of the corporation in the year 1227. From this period to 1555, we are totally in the dark as to its history or condition; nor is there any thing worth remarking for the 16 years following, when the inhabitants sent a memorial to queen Elizabeth, praying relief from a subsidy which her ministers had imposed upon them. In this petition they style themselves "her majesty's poor decayed town of Liverpool." How the town became so "decayed," it is now difficult to comprehend, as, from the records several years previous, it does not seem to have been any better than a fishing hamlet, containing about 138 householders and cottagers, and possessing 12 barks, navigated by 75 men. Camden, however, who wrote in 1586, considered it in his time as more famous for its beauty and populousness than for its antiquities. To reconcile these opposite statements, it is only necessary to admit, that a very trifling village may arrive at considerable opulence in the short period of 21 years; and who will deny the possibility of such an event at the present day? From Camden's time nothing is recorded of Liverpool deserving of notice till the year 1644; when the town and its castle were possessed by the parliamentary troops, under colonel Moore. It was fortified and secured on the land side by a high mud wall, and a ditch twelve yards wide and three deep. Batteries were erected at different points, and the ends of the streets were defended by artillery. The garrison was numerous, and being well stored with provisions, made a most vigorous defence for the space of a month. At last, however, the king's army, under the orders of prince Rupert, succeeded in taking the town, when the castle surrendered without further resistance. Some traces of this siege can yet be discovered at different points. When the foundation of the present infirmary was sunk, the marks of trenches were distinctly visible, and many articles of modern warfare were found within their scope. A few years ago, as some workmen were removing the earth in a field where Gloucester-street now stands, they laid open the foundation of a battery, and discovered military utensils of different kinds. From the time of the siege till 1680, we have a tolerable account of the progress of the town in extent and population. After this period, however, we are again left in obscurity, and receive no authentic information on that head till the year 1765, when we find a plan of the town made by Mr. John Lyes. About this time, says Enfield, Liverpool contained about 4200 houses, and 25,000 inhabitants. It had, in the interval last-mentioned, been constituted a distinct parish from that of Walton, to which its

church had formerly been only a dependent chapel. This event took place in 1698, when the inhabitants were likewise authorized to build a second church. Thus emancipated from parochial subservience, Liverpool began to display its energies. In the short space of little more than half a century, this town, aided by a few favourable circumstances, has risen to great commercial importance, and may be considered to be next to the metropolis itself. She first rivalled, and latterly surpassed, Bristol, which had long been considered as the western emporium of trade.

The following table exhibits the progressive increase of the dock duties for several years, and serves to display the vast and rapid increase of the commerce of the town. It shews the number of vessels that have been affixed in each year, with the aggregate sum paid to the dock companies.

Years.	Ships.	£.	s.	d.
1760	1245	2,330	6	7
1765	1930	3,455	8	4
1770	2 73	4,142	17	2
1775	2291	5,384	4	9
1780	2261	3,528	7	9
1785	3429	8,411	5	3
1790	4223	10,037	6	2
1795	3948	19,368	16	4
1800	4746	23,337	13	6
1802	4781	28,192	9	10
1805	4618	33,364	13	1
1807	5791	62,831	5	10
1809	6023	97,580	19	3

The boundaries of Liverpool extend considerably beyond the town in different directions. These are marked out by stones called by the inhabitants meer-stones, and the ground contained within them is denominated the liberties. The extent of the liberties from east to west, is somewhat more than a mile and two furlongs, and from north to south considerably above two miles. This town exhibits, in general, the appearance of opulence and refinement. The streets are well paved, and during winter tolerably furnished with lamps. Of late years it has received many great alterations and improvements, which still continue to proceed notwithstanding the pressure of the times. In the year 1790, it consisted of 8865 houses, but their number now is little short of 15,000.

Liverpool possesses fifteen churches belonging to the establishment, some of which are worthy the particular attention of the stranger. Near the old church, which is dedicated to our Lady and St. Nicholas, there formerly stood an image of the latter, to which the sailors were accustomed to make offerings on going to sea. This church has been lately rebuilt. The tower of St. Peter's, which was erected in 1704, is a well-proportioned octagon, each side of the angles having a candlestick and gilt vase representing a flame. This and St. Nicholas are the parish churches, and have two rectors over them. The church of St. George, built on the site of the ancient castle already mentioned, is a fine edifice of the Doric order, crowned with an attic wall, and adorned with a variety of vases. On each side is a terrace with recesses underneath. The interior is handsomely fitted up, the fronts of the galleries being mahogany. This is the mayor's chapel, where he attends every Sunday, and where pews are appropriated for the gentlemen, including strangers, who choose to accompany him. St. Thomas's church is of the Ionic order, and has a handsome appearance. It was consecrated in 1750. St. Paul's church was erected by the town in 1760. At the west end is a portico with a pediment, having in the centre, on an octagonal base, a dome

LIVERPOOL.

with a lantern, ball, and cross. The interior is supported by eight Ionic pillars. The altar is plain and neat. The church dedicated to St. Ann, on the road to Everton, is a neat building of brick and stone. It was erected at the joint expense of two private gentlemen. It has a tower decorated with pinnacles. St. John's church is a new building of stone, with a tower. St. Mary's and the other churches have nothing connected with their structures or appearances deserving of particular notice: though all of them are entitled to be called neat. Besides the places of worship belonging to the establishment, there are a great number of dissenting meeting houses, or chapels, for various descriptions of religionists.

The public edifices connected with the trade and commerce of the town are, the exchange buildings, town-hall and mansion house, custom-house, corn exchange, tobacco warehouse, and other warehouses. Of these the Liverpool exchange is the most spacious in plan, and ornamental in its exterior architecture. It has been erected by a subscription of 80,000*l.* raised by 800 transferable shares. The buildings occupy three sides of a quadrangle, having the town-hall on the fourth side. The whole surrounds an area of 194 feet by 180. It has been built by John Forster, esq. (architect, engineer, and dock master to the corporation) from designs by James Wyatt, esq. architect; and is appropriated to a public exchange rooms, coffee rooms, and various offices. The town-hall, formerly called the exchange, is a large insulated pile of building, the greater part of which was erected in 1750, from the designs of Wood of Bath. The whole of its interior was burnt in 1795. It was soon repaired, and appropriated to the use of the mayor, for offices belonging to the corporation, sessions rooms, &c.

The infirmary is another excellent building of brick ornamented with stone. This establishment not only extends to all proper objects within Liverpool, but to every person whom sickness or bodily misfortune may lead to apply, provided they are recommended by a subscriber. The seamen's hospital forms a portion of the buildings of this infirmary, being attached to it by a handsome colonnade. The blue-coat hospital is placed in an airy situation adjoining to St. Peter's church-yard. It is a large handsome building of brick ornamented with stone. The number of persons who annually receive the benefits of this charity are about 280. The expence of this institution is defrayed chiefly by benefactions.

The poor-house is a handsome edifice, 90 feet long and 24 broad, built in a plain style, and in a manner very suitable to its use. On the east side of this structure is a handsome stone building, called the "recovery ward," where persons infected with fevers, and coming under the cognizance of physicians and surgeons of the dispensary, are received. A variety of alms-houses range out on both sides of the poor-house. In Church-street is the dispensary, which is a very good brick building, with a large circular portico, and having in front a small bas-relief of the good Samaritan. This institution is conducted by a president, two auditors, seven physicians, three surgeons, and one apothecary, who officiates as secretary. Two physicians and a surgeon attend every day at certain hours. About 10,000 persons are said to receive medicine and advice here annually. The Lunatic-asylum is contiguous to the infirmary, but, like most other institutions of the kind, cannot be called a complete charity, as patients are not admitted free of expence. At the entrance into the town, on the road leading from Prescot, stands the school of industry for the indigent blind. The original projector was Mr. John Christie, who was him-

self unfortunately deprived of his sight at the age of 19. In this school pupils are taught various trades, which enable many of them to make a comfortable provision for life. Besides these charitable institutions there are a number of others, under different names, intended for the relief of different descriptions of persons, which the limits of an article like this will not permit us to mention particularly.

Liverpool abounds, as may be supposed from its great trade, with rooms appropriated for public correspondence, and the transacting of business. The Atheneum, which comprises a news-room, a library, &c. is situated on the fourth side of Church-street, and is a handsome building of stone. The subscribers to this institution, about 450 in number, are supplied with the London and provincial newspapers, the shipping and trade lists, and various periodical publications. Every subscriber is allowed the privilege of introducing his friend, provided he be a non-resident of the town. There also several more institutions of a similar kind in different parts of the town. Of these, the Lyceum is the first and most worthy of attention. It is situated at the bottom of Bold-street, and is another remarkable instance of the munificence and public spirit of Liverpool. An academy, for the encouragement of the fine arts, has recently been established in this town. The places of public amusement are now little inferior to those in the metropolis. The theatre is a spacious and commodious building, and but little inferior to that of Covent-garden in the extent of its stage. It generally opens at the time the London houses shut, when many of the first performers resort to it. In Bold-street stands the Music-hall, which was opened in 1785. It is a large building, finished with great elegance. The new prison, according to the Howardian plan for solitary confinement, is on a very extensive scale, and has every possible convenience.

Liverpool abounds in docks for the safety and repair of its numerous shipping. The first dock was constructed here in 1710. Its site was the pool, from which the town derived the latter portion of its name. This basin of water is called the old dock, and is principally the receptacle of West India and African ships, being contiguous to the warehouses of the merchants engaged in those branches of commerce. The King's dock is 290 yards in length, and 92 wide. On the east side of this dock stands the tobacco warehouse, where that article is lodged by the custom-house officers till the duties are paid. It was erected by the corporation, and is rented by government at 500*l.* *per annum.* St. George's dock was the third made in Liverpool. It is about 250 yards long, and 100 broad; and is esteemed commodious. The largest, last constructed, and best finished however of the Liverpool docks, is the Queen's dock, which is situated at the bottom of Parliament-street. Salt-house dock, which is the second oldest of the whole, comprises an area of 21,28 square yards; and has a length of quay of 640 yards. Besides these there are five graving docks, and three dry docks, independent of a small one, which belongs to the earl of Bridgewater, for the use of the canal flats. Some of these docks communicate, so that ships can pass from one to the other, and into the graving docks, without being obliged to go into the river. All the wet docks are likewise connected by large tunnels, for the purpose of one dock cleaning or washing another. When large ships loaded arrive at neap tides they are compelled to remain in the river till the flow of the spring tides, as the dock gates have not depth of water sufficient to admit them. This circumstance is certainly a great inconvenience, but it is amply compensated by the capaciousness and excellent arrangement of the docks themselves.

The

The custom-house is situated at the east end of the old dock. It is built of brick, in rather a neat style. A small flight of steps leads to a piazza, over which is the long room, and behind it are extensive warehouses. At the south end of the town is St. James's walk, from which the spectator has a fine view of the town, the harbour, the river, the sea, and the Welsh mountains. Behind this lies an excellent quarry, the entrance of which is by a subterraneous passage, supported by arches. Bottle-springs, about four miles distant from Liverpool, furnish the town with water, which is conveyed by means of pipes.

The principal manufactures are those of china and earthen ware, the several branches of the watch-making, and extensive salt, iron, and copperas works. It is computed that about 3000 shipwrights are constantly employed in the different dock-yards of this town. The river, which is here about 1200 yards broad, abounds with salmon, cod, flounders, and turbot. Ships of any burden may come up to this town with perfect safety, even at the lowest tides. The accommodations for sea-bathing have, of late years, received vast improvements, and are not perhaps inferior to any in the kingdom.

Liverpool undoubtedly owes all her opulence and grandeur to the spirit and enterprise of her merchants. She exhibits, to the eye of the statesman and philosopher, a distinguished instance of the rapid progress of commercial greatness. A century ago, a few coasting vessels and petty traders formed the whole of her wealth. For the first fifty years her advance was comparatively slow. After this period, however, the increase of trade which the every year acquires, is truly astonishing. She shares a portion of the commerce of almost every country in the world. Of late years, Liverpool has considerably decreased, in common with that of all the other towns in the kingdom. What effect the abolition of the slave-trade may ultimately have upon Liverpool, it is not possible to prognosticate. For the present, however, the mercantile houses, formerly engaged in that traffic, must undoubtedly suffer considerable difficulties before they can turn their capital and attention to some object more honourable than the purchase and sale of human beings.

Independent of the advantages Liverpool possesses for foreign commerce, it has communication with all the interior counties by canals. These again, being joined by others at different points, extend themselves to the Severn, to the Humber, and to the Thames; thus connecting the four principal trading ports in England. To the beneficial effects of these canals Liverpool has to attribute much of her present greatness.

The markets of Liverpool are well supplied with every necessary of life, and every article of luxury. About 3000 cattle and sheep are brought into the town weekly. The market days are Wednesdays and Saturdays. Liverpool sends two members to parliament. The number of electors amounts to above one thousand. The corporation consists of a mayor, two bailiffs, and a common-council. The mayor and bailiffs are assisted by a recorder, a town clerk, and other necessary officers. The revenues of the town are very great. Enfield's History, &c. of Liverpool, folio. A General and Descriptive History of Liverpool, by Wallace, 8vo. 1797. The Picture of Liverpool, 12mo. 1805. Beauties of England, vol. ix.

LIVERPOOL, a town on the S. side of the bay of Fundy, in Queen's county, Nova Scotia, settled from New England. Between this town and Annapolis lies a considerable lake, called Rossignol. It is 32 miles N.E. of Shelburne,

and 58 N.W. of Halifax, and was formerly called "Port Rossignole."

LIVERY, properly signifies a colour, to which a person has some particular fancy, and by which he chooses to distinguish himself, or his retainers, from others.

Liveries are usually taken from fancy, or continued in families by succession. The ancient cavaliers, at their tournaments, distinguished themselves by wearing the liveries of their mistresses: that people of quality make their domestics wear their livery.

Father Menestrier, in his Treatise of Carousals, has given a very ample account of the mixtures of colours in liveries. Dion tells us, that Cæneaus was the first who invented green and blue colours for the troops which, in the Circus, were to represent land and sea-fights.

The Romish church has also her several colours and liveries; white, for confessors and virgins, and in times of rejoicing; black, for the dead; red, for the apostles and martyrs; blue or violet, for penitents; and green, in times of hope.

Formerly, great men gave liveries to several, who were not of their family or servants, to engage them in their quarrels for that year; but this was prohibited by the statutes 1 Rich. II. 1 Hen. IV. cap. 27. 2 & 7 Hen. IV. 8 Hen. VI. cap. 4. 8 Ed. IV. cap. 2. and no man, of whatever condition, was allowed to give any livery, but to his domestic officers, and counsel learned in the law. However, most of the above statutes are repealed by 3 Car. I. cap. 4.

LIVERY, in Law, also denotes the delivery of possession to those tenants which held of the king in capite, or by knights' service. See POSSESSION.

LIVERY is also used for the writ, which lies for an heir to obtain the possession or seisin of his lands at the king's hands. By 12 Car. II. cap. 24. all wardships, liveries, &c. are taken away. See COURT of Wards.

LIVERY of seisin, is a delivery of possession of land or tenements, or things corporeal, to him who hath right, or probability of right, to them.

Livery of seisin is a ceremony used in the common law, on conveyance of lands, tenements, &c. where an estate in fee-simple, fee-tail, or other freehold, shall pass; and is a testimonial of the willing departing of him who makes the livery, from the thing whereof the livery is made, as well as of a willing acceptance by the other party, of all that whereof the first has divested himself. (See FREEHOLD.) On the creation of a freehold remainder, at one and the same time with a particular estate for years, at the common law livery must be made to the particular tenant. (See ESTATE and REMAINDER.) But if such a remainder be created afterwards, expectant on a lease for years now in being, the livery must not be made to the lessee for years, for then it operates nothing; "Nam quod semel meum est, amplius meum esse non potest;" but it must be made to the remainder-man himself, by consent of the lessee for years: for without his consent no livery of the possession can be given (Co. Litt. 48.); partly because such forcible livery would be an ejectment of the tenant from his term, and partly for the reasons assigned for introducing the doctrine of attornments.

Livery of seisin is either in *deed* or in *law*.

The usual manner of livery of seisin in *deed* is thus performed. If it be in the open field, where is no house nor building, and if the estate pass by deed, the feoffor, lessor, or his attorney, openly reads it, or declares the effect of it; and after that is sealed, the feoffor takes it in his hand, with a clod of earth, or a twig or bough, which he delivers to the feoffee, in the name of possession, or seisin, according to the

the purport of the deed. If there be a house or building on the land, the ceremony is to be done at the door of it, none being then left within; and the ring or latch of the door is delivered to the feoffee, who enters alone, shuts the door, and presently opens it again. If it be a house without land or ground, the livery is made, and possession given, by delivery of the ring or latch of the door and deed only; and where it is without deed either of lands or tenements, there the party declares by word of mouth, before witnesses, the estate he parts with; and then delivers seisin, or possession, as aforesaid: in which case the land passes as well as by deed, by virtue of the livery of seisin. Co. Litt. 48. West Symb. 251.

If the conveyance or feoffment be of divers lands, scattered in one and the same county, livery of seisin of any parcel in the name of the feoffor, sufficeth for all (Litt. § 414.); but if they be in several counties, there must be as many liveries as there are counties. If the lands be out on lease, though all lie in the same county, there must be as many liveries as there are tenants. (Dyer 18.) In all these cases it is prudent to endorse the livery of seisin on the back of the deed, specifying the manner, time, and place of making it, together with the names of the witnesses. Livery *in loco* is where the same is not made on the land, but only *in sight* of it; the feoffor saying to the feoffee, "I give you yonder land, enter and take possession." However, this livery in law cannot be given or received by attorney, but only by the parties themselves. Co. Litt. 48. 52.

Anciently, there were a pair of gloves, a ring, knife, an ear of wheat, &c. delivered in sign of livery and seisin.

LIVERYMEN of London, are a number of persons chosen out of the freemen of each company. (See COMPANY.) Out of this body the common-council, sheriffs, aldermen, and other officers for the government of the city are elected; and they only have the privilege of giving their votes in common-hall for members of parliament, &c. from which the rest of the citizens are excluded. If any one of the company refuse to become a liveryman, he may be fined, and an action of debt will lie for the sum.

LIVERYMEN, in *Natural History*, a name given by authors to a sort of caterpillars, remarkable for their variety of colours. These are of that class of caterpillars which live in communities, and build themselves nests to defend them from the injuries of the weather. They may be ranked among the processionary kinds, always following one another with great order in their marches; but what is most surprising, is to see them straggle very far from their nests, and this often, by several repeated windings and turnings, without losing their way. Their art, in doing this, deserves notice, and is the same by which Theseus got out of the labyrinth of Crete. Phil. Transf. N^o 470. p. 459.

LIVIA DRUSILLA, in *Biography*, a celebrated Roman lady, daughter of Livius Drusus Calpurnianus, who joined the party of Brutus and Cassius, and killed himself after the battle of Philippi. She married Tiberius Claudius Nero, by whom she had two sons, Drusus and the emperor Tiberius. The attachment of her husband to the cause of Antony was the beginning of her greatness. Octavianus, afterwards the emperor Augustus, saw her as she fled from the danger which threatened her husband, and resolved to marry her, though she was then pregnant. He accordingly divorced his wife Scribonia, and with the approbation of the augurs he celebrated his nuptials with Livia. She from this moment enjoyed the entire confidence of the emperor, and was in fact the partner of his whole reign, enjoying a large share of his power and imperial dignity. She gained a complete ascendancy over the mind of Augustus by a constant obedience to

his will: by never expressing a desire to dive into his secrets, and by affecting ignorance of his amours. Her children by Drusus were adopted as his own by the complying emperor; and that she might make the succession of her son Tiberius, Drusus being dead, more easy and undisputed, Livia has been accused of secretly involving, in one common ruin, the heirs and nearest relations of Augustus. There are facts adduced which seem to render the suspicions of her baseness and cruelty wholly without foundation. She has been charged with administering poison to her husband, which is rendered exceedingly improbable by the account we have of his last illness, and by the tenderness he expressed for her in the last words he uttered. By his will she was instituted co-heiress with Tiberius, adopted as a daughter, and directed to assume the name of Julia Augusta. On his deification she became the priestess of the new god. Tiberius, whose elevation had been the object of her policy, disappointed her expectation of sharing with him the imperial power. He took pains indeed to subject her to various mortifications: and at length there was an open rupture between them. She died in the year 29.

Tiberius neglected her funeral, and would not permit public or private honours to be paid to her memory. Tacitus has drawn her character, saying, that "in strictness of conduct she was not inferior to the Roman matrons of old, though her demeanour was freer than they would have approved; that she was an imperious mother, a compliant wife, and a match for her husband in art, and her son in dissimulation."

LIVIA, in *Ornithology*, a name given by some authors to a particular species of pigeon called *palaus* by the Greeks. It is very like the common pigeon in shape, but is somewhat smaller, its legs are red, and its beak white, except that it is a little purplish about the nostrils.

It is all over grey, but that the end of its tail-feathers are black, and there is a purplish and greenish variegation about the sides and shoulders. And its wing-feathers have some white variegations, as has also the lower part of the neck. It is supposed by Mr. Ray, and some others, to be the same with the *passerella* of the Italians, or *columba rupicola*. See COLUMBA.

LIVINEIUS, JOHN, in *Biography*, a learned Flemish divine, was born at Dendermond about the year 1540. Being intended for the church, he pursued his academical studies at Cologne, entered into holy orders, and was in a short time presented to a rich benefice at Liege. He was afterwards promoted to a canonry, and appointed preceptor in the cathedral church of that city. He engaged in the superintendence of the edition of Pantin's Greek bible, and translated into Latin some of the works of the Greek fathers, and was about giving to the public all the works of St. Gregory of Nyssen, when he was cut off by death in 1599. He published "Emendationes et Notae in XII. Paenynicos Vetus," and other learned works; and left behind him in MS. translations of the tragedies of Euripides, and of the works of Athenaeus. Gen. Biog.

LIVINETHAL, in *Geography*. See LEVANTINE Valley.

LIVINGSTON, a county of Kentucky, in America, bounded N. by the Ohio, W. by the Mississippi, and S. by Tennessee; 70 miles long and 60 broad. The principal rivers are the Cumberland and Tennessee. It contains 2787 inhabitants, of whom 414 are slaves. Also, a large township in Columbia county, New York, extending from the E. bank of Hudson river to the Massachusetts line, S. of Hudson adjoining. It contains 7405 inhabitants, of whom 213 are slaves.

LIVISTONA, in *Botany*, named by Mr. Brown, in memory of the right honourable Patrick Murray, lord Livistone, the friend of sir Andrew Balfour, who, when the Edinburgh botanic garden was first established, greatly enriched it from his own private collection, where he had above a thousand species in cultivation. This nobleman travelled over France in search of plants, where he died of a fever, about the middle of the seventeenth century. Brown Prodr. Nov. Holl. v. 1. 267. — Class and order, *Hexandria Monogynia*. Nat. Ord. *Palmæ*.

Eff. Ch. Calyx deeply three-cleft. Corolla deeply three-cleft. Filaments separate, dilated at their base. Germens three, cohering. Styles three, united into one. Stigma undivided. Berry solitary, of one cell. Seed solitary; albumen with a ventral cavity; embryo at the back.

A genus of Palms, whose leaves are palmate, or somewhat pinnate, their segments cloven at the extremities. It should stand between *Corypha* and *Chamærops*. *Latania chinensis* of Jacquem's *Fragmenta*, p. 16. t. 11. f. 1, is thought by Mr. Brown to belong to this genus. Two species of it were found by him in the tropical part of New Holland.

1. *L. inermis*. Segments of the leaves with intermediate threads. Footstalks without thorns. Stem from 14 to 30 feet high.

2. *L. humilis*. Segments of the leaves with intermediate threads. Footstalks thorny. Stem from four to six feet high.

LIVIUS ANDRONICUS, in *Biography*, is regarded as the most ancient of the Roman poets. He was the first who attempted to compose a drama in verse, which he himself sung and acted, while a player on the flute accompanied him in unison to keep him in time. He was ecored and obliged to repeat his pieces so often, that he lost his voice; and being unable to sing or declaim any longer, he was allowed to have a slave to sing, while he only acted the part behind him. Hence came the custom of dividing the declamation or melody of the piece, with which the Roman people were extremely delighted. This poet flourished 240 B. C. Livy and Priestley.

LIUNG, in *Geography*, a town of Sweden, in West Gothland; eight miles S. of Uddevalla. — Also, a town of Sweden, in East Gothland; eight miles N.N.W. of Linköping.

LIUNGBY, a town of Sweden, in the province of Skonen; 16 miles E. of Helsingborg.

LIVNI, a town of Russia, in the government of Orel, on the Sosva; 84 miles E. of Orel. N. lat. 52° 58'. E. long. 38° 22'.

LIV OE, a small island of Denmark, in Lymfiord gulf; having upon it a village. N. lat. 56° 53'. E. long. 9° 6'.

LIVONIA, the name of an ancient province of Russia, which, including *Esthonia* (which see), lies in N. lat. 58°, and is bounded on the N. by the gulf of Finland, on the E. by Novogorod, on the S. by Poland, and on the W. by the Baltic; being 190 miles from N. to S., and 180 from W. to E., and containing 725,300 inhabitants. This province abounds in lakes, forests, marshes, and rivers; but many districts are exceedingly fertile, yielding great quantities of rye and other grain, flax, hemp, and linseed, which are exported to Sweden, Germany, and other countries; so that Livonia has been called the granary of the north. It has several good harbours conveniently situated for trade. Peipus lake, about 15 leagues long, and ten broad, has a communication with the gulf of Finland by the river Narva. This country, formerly claimed by several neighbouring princes, frequently changed masters. Livonia, or Lettland, as it was called, together with Esthonia, Courland, and Semigallia,

being provinces on the Baltic, belonged in the earliest times to the Russian state, and had even a share in the founding of it. (See *LETES*.) But Livonia had then no settled constitution, nor was it bound to the parent state by any firm political tie. To the rest of Europe it remained generally unknown, till in the year 1158 it was discovered by some merchants of Bremen, in their search of new branches of commerce towards the north. These mariners landed at the mouth of the Duna, opened a trade with the inhabitants, returned thither several times, and at length proceeded, with the consent of the natives, along the shores of the Duna, or Dwina, many miles up the country. About eighteen years after the discovery, an Augustine monk, named Meinhard, settled in Livonia, profelyted the Livonians to Christianity, and became their bishop, upon which many Germans, at various times, were induced to repair thither also. The time of the arrival of Meinhard is not precisely ascertained. Some pretend that it was in 1170, others in 1186. The success of the monk was promoted by the service which he rendered to his own countrymen, in repelling the Lithuanians, who had made an incursion upon them. He flated to them the necessity of constructing a strong fortress, and he aided them in accomplishing this object, on condition of their being baptized. But they were reluctant in complying with this condition, and many of them relapsed to Paganism. Meinhard was disappointed in his benevolent efforts, and prevented by force from returning with his clergy to Germany, he died among them, more of grief than of age. After his death, Berthold, abbot of the monastery of Lockum, in Hanover, was elected bishop, and arriving in Livonia, though not without reluctance, in the year 1197, he recommended himself by giving them frequent entertainments: but the ardour of their attachment soon abated, and he was constrained by ill usage to leave the country. He applied to Gothland and to Lower Saxony for succour; and the pope assisted him by causing a crusade to be preached against the heathens of Livonia. In 1198 he returned thither with an army of foldiers. The Livonians prepared to fight, took the field to resist the invaders. A truce was concluded, which was soon broken on the part of the heathens, by the assassination of several Germans. Berthold declared war, and in a bloody battle which ensued, fell by the sword. The heathens, however, were at length routed, and when their corn-fields were laid waste by the Christians, they sued for peace, and flocked in numbers to be baptized. Upon this the Germans returned home; but they were no sooner embarked, than the Livonians bathed in the Dwina, in order, as they said, to wash away their baptism and Christianity together. They also plundered those that remained, and put upwards of 100 to death. The Livonians also resolved, that all priests who should be found in the country after Easter 1199, should be slain. A similar fate also awaited the merchants. These ransomed their lives, but the clergy were forced to fly to Lower Saxony. The monk Meinhard, and the abbot Berthold, were succeeded by Albrecht, who, being elected bishop, arrived in Livonia with twenty-three ships. The Livonians became Christians for fear of starving. Albrecht employed valiant men, from whom the bishopric might expect continual protection; and with this view he gave ample fiefs to some courageous nobles. He established also a standing army, and devised other methods for establishing Christianity in the country. In 1201 he built the city of Riga, and transferred thither the cathedral chapter, where he also built a monastery. In the mean while the clergy dispersed themselves through the country, in order to teach and to baptize. In process of time other means were used to accomplish the conversion of the Livonians.

nians. In the year 1205 Andrew, archbishop of Lunden, visited Riga, and having acquired the reputation of a learned divine by his studies in Italy, France, and England, gave lectures of theology to the clergy of that city; and by his advice the vicar of the bishop of Riga sent priests among the Livonians, divided the country into distinct parishes, and caused them not merely to be baptised, but to be previously instructed. Churches were also erected. From Livonia Christianity was diffused, against much opposition, among the Esthonians. In the year 1522, the reformation found its way into Liefland, by a preacher, who, having been driven out of Pomerania, fled to Riga. The doctrine of Luther was eagerly embraced; and the Popish ritual, afterwards patronized on the part of Poland, had, on the whole, no influence to its detriment. By the tenth article of the treaty of Nyitadt, the Greek religion is secured in the free exercise of its rites. In Riga there is a church for the use of the Calvinists, and the Catholics are allowed the exercise of their worship. In Liefland it may be justly said that every man may follow his own persuasion in matters of religion without the least molestation. Here also count Zinzendorf has found many friends to his church institution.

Soon after the conversion of the Livonians, the bishop, in the year 1201, founded the order of the Sword-brethren, afterwards called Knights-Templars, and granted them the third part of the country with all rights of sovereignty, for conquering and preserving Livonia. These knights were all Germans, who profolyted the natives to Christianity with great success, though not without bloodshed, and made them their vassals. They afterwards united themselves with the Teutonic order in Prussia, to whom Valdimar III., king of Denmark, in 1386, sold Esthonia for the sum of 18,000 marks of standard gold. In the year 1521 the Livonian heermeister Plettenberg again separated from the Teutonic order, and was admitted by the emperor Charles V. among the princes of the German empire. The attempts made by Czar Ivan Vassilievitch II, to reconquer these provinces which had been torn from the Russian empire, and the weakness of the order, which felt itself not in a capacity to resist so powerful an enemy, at length, in 1561, effected the complete separation of the Livonian state. Esthonia put itself under the protection of Sweden, Livonia united with Poland, and Courland was a peculiar dukedom under Polish supremacy, which the last heermeister Gotthard Kettler held as a fief of that crown. From this era Livonia became the unhappy object of contention, for which Sweden, Russia, and Poland, for an entire century, were continually exhausting themselves in bloody wars. Sweden at last obtained the dominion, and at the peace of Oliva in 1660 added this province to the possession of Esthonia. Both countries finally, after a war of 20 years, came to the Russians by the treaty of Nyitadt in 1721; and form at present the vicerealties of Riga and Revel. These two governments are supposed to contain 24,000 geographical square miles. This country formerly contained a considerable number of towns and villages, but by wars and intestine commotions, most of them were destroyed. See RIGA and REVEL.

The tract of country called Polish Livonia, which, under the government of the Teutonic order, formed likewise a part of the Livonian state, reverted in the year 1561, with the whole province of that name, to Poland. At the peace of Oliva, by which Livonia came under the sovereignty of Sweden, this sole district however remained to the Polish state, retaining from that time its name in contradistinction to Swedish Livonia. On the partition in 1773, this country, which had hitherto constituted its particular voivodeship, was annexed to Russia, and now comprehends the two circles of

Dunaburg and Refitza, in the vicerealty of Polatsk. Tooke's View of the Russian Empire, vol. i.

LIVONICA TERRA, in the *Materia Medica*, a kind of fine bole used in the shops of Germany and Italy, of which there are two species, the yellow and the red. (See BOLE.) The distinguishing characters of which are these.

The yellow Livonian earth is a pure and perfectly fine bole, of a shattery friable texture, considerably heavy, and of a dull dusky yellow, which has usually some faint bluish redness in it. It is of a smooth surface, and does not stain the hands; it adheres firmly to the tongue, and melts freely in the mouth, leaving no grittiness between the teeth, and ferments not at all with acid menstrua. In a moderate fire it acquires some additional hardness, and a darker colour. It has been esteemed a sudorific and an astringent.

The red Livonian earth is an impure bole of a loose texture, and a dull red. It is of a smooth surface, breaks easily between the fingers, and slightly stains the hands. It melts freely in the mouth, has a very strong astringent taste, but leaves a grittiness between the teeth, and is alkaline. It acquires a considerable hardness in the fire, and becomes of a paler colour with a strong cast of yellowish-brown.

These earths are both dug out of the same pit, in the place from whence they have their name, and in some other parts of the world. They are generally brought to us made up in little cakes, and sealed with the impression of a church, and an escutcheon with two cross keys, and recommended in diarrhœas, dysenteries, &c.

LIVORNINA, an old coin of Leghorn, equal in value to 4s. 5½d. sterling.

LIVORNO, in *Geography*. See LEGHORN.

LIUR, a town of Sweden, in West Gothland; 33 miles N.E. of Gotheborg.

LIVRE, a French money of account, in the old system, consisting of twenty sols; each sol containing twelve deniers and four liards.

The origin of the word is derived hence, that anciently the Roman libra, or pound, was the standard by which the French money was regulated; twenty sols being made equal to the libra. By degrees the libra became a term of account; so that any coin just worth twenty sols was a livre, or libra; and since the time of Charlemagne, all contracts have been made on the foot of this imaginary coin; though the sols have frequently changed their weight and alloy.

The livre is of two kinds, *Tournois* and *Paris*.

LIVRE *Tournois*, as above, contains twenty sols Tournois, and each sol twelve deniers Tournois.

LIVRE *Paris*, is twenty sols Paris, each sol Paris worth twelve deniers Paris, or fifteen deniers Tournois; so that a livre Paris is equivalent to twenty-five sols Tournois; the word Paris being used in opposition to Tournois, on account of the rate of money, which was one-fourth higher at Paris than at Tours.

The franc and livre were formerly synonymous; but in the coinage of 1795, the franc was made too heavy, and its value was accordingly raised 1¼ per cent.; thus, 80 francs = 81 livres. In 1796, it was ordered that the piece of five francs should pass for five livres one sol three deniers Tournois, from which the proportion of the franc to the livre of 100 to 101½ is determined; but the accuracy of this proportion has been questioned by writers of the first authority, who have calculated it to be as 100 to 101½. See COINS, EXCHANGE, and MONEY.

For an account of the coin and money of account, both under the old and new system of 1795, see MONEY.

There have since been pieces of gold struck of twenty sols value;

value; and under Henry III. in 1575, pieces of silver of like value: both the one and the other were called *frances*; and thus the imaginary coin became real. It appears that the Romans had also a kind of money, which they called *libra*, or *libella*; which was the tenth part of their denarius; so called, because equivalent to an *as*, which at first weighed a *libra* or pound of copper. Scaliger adds, that they used *libra* as a term of account, not as a coin: "*Libra erat collectio nummorum non nummus.*"

LIVRE OUVERT, *Fr. in Mus.* To sing or play a *livre ouvert*, is equivalent to playing or singing *à sight*, at the opening of a book. All musicians pique themselves on being able to perform a musical composition at sight, without previous study or practice; but Rousseau very justly observes, that there are few who, in this kind of execution, seize the true spirit of the author, and who, though they hit the right notes, do not mistake the expression.

LIUSDAL, in *Geography*, a town of Sweden, in the province of Helmingland; 32 miles W.N.W. of Hudwicksf-wal.

LIUSNABRUCK, a town of Sweden, in the province of Helmingland; 5 miles S. of Soderhamm.

LIUSNAN, a river of Sweden, which rises in the mountains of Harjedalen, and discharges itself into the gulf of Bothnia; 8 miles S. of Soderhamm. N. lat. 61° 15'. E. long. 17°.

LIUSTARNO, an island of Sweden, in the Baltic. N. lat. 59° 30'. E. long. 18° 30'.

LIUSTORP, a town of Sweden, in Medelpadia; 15 miles N. of Sundfwall.

LIUSUDBORG, a town of Sweden, in Nericia; 40 miles N. of Orebro.

LIUTPRAND, in *Biography*, an historical writer of the tenth century, said by some authors to have been a Spaniard, by others an Italian. His father was in the confidence of Hugo, king of Italy; and the son, while very young, was placed in the court of Berenger II., who obtained the kingdom by dispossessing Hugo, and was sent by him ambassador to the Greek emperor, Constantine Porphyrogenitus, on account of his intimate acquaintance with the Greek language. Losing the favour of his own master, he was obliged, in 958, to go an exile to Germany, where he composed the history of his own times, which is extant. The fall of Berenger, who was stripped of his dominions, in 961, by Otho I., restored Liutprand to his country; and he was soon after consecrated bishop of Cremona. In quality of this office, he attended an assembly of bishops at Rome in 963, in opposition to the pope, John XII. He was again sent as ambassador to the court of Constantinople, in the name of Otho, to solicit the daughter of the Greek emperor for the son of Otho: he was unsuccessful; and being much hurt at the reception he met with, he satirized the pride and ignorance of the court in an account of his embassy, annexed to his history. The time of his death has not been ascertained; but his signature occurs in a synod held at Ravenna in 975, under the title of Lixzio, bishop of Cremona. This historical work of Liutprand consists of six books, of which some of the latter chapters are supposed to have been written by another hand. It has passed through several editions: the last is that of Muratori, in his "*Scriptores Rerum Ital.*"

LIUTZEN, in *Geography*, a town of Russia, in the government of Polotsk; 60 miles N.N.W. of Polotsk. N. lat. 56° 25'. E. long. 27° 34'.

LIVY, **TITUS LIVIUS**, in *Biography*, an eminent Roman historian, is supposed to have been a native of Padua. He came to Rome in the reign of Augustus, and was ad-

mitted to the familiarity of several persons of rank, and of the emperor himself. He made himself known by some philosophical dialogues; but his literary reputation was principally built upon his Roman history, which enjoys a perpetual celebrity: no work of the kind was ever received with greater applause. Few particulars of his life are known; yet his fame was so universally spread, even in his life time, that a person traversed Spain, Gaul, and Italy, merely to see the man whose writings had given him such pleasure and satisfaction in the perusal. Livy died at Padua in his 67th year, and, according to some, on that same day Rome was also deprived of another of its brightest ornaments by the death of Ovid. Livy wrote a letter, addressed to his son, on the merit of authors, which is greatly commended by Quintilian, who expatiates with great warmth and ardour on the judgment and candour of the writer. His Roman history was comprehended in 140 books, of which only 35 are extant. It began with the foundation of Rome, and was continued till the death of Drusus in Germany. The merit of this history is well known, and the high rank which Livy holds among historians will never be disputed. His style is clear and intelligible, laboured without affectation, disfluent without tediousness, and argumentative without pedantry. His descriptions are singularly lively and picturesque; and there are few specimens of oratory superior to that of many of the speeches with which his narratives are copiously interspersed. Of the editions of Livy, those most esteemed are that of Gronovius cum Notis variorum, 3 vols. 8vo. Lugd. B. 1679; of Le Clerc, Amst. 10 vols.; of Crevier, 6 vols.; of Drakenborch, Amst. 7 vols. Livy's works have been divided by some moderns into 14 decades, each consisting of 10 books. The first decade comprehends the history of 460 years. The second decade is lost, and the third includes the history of the second Punic war, or a space of about 18 years. In the fourth decade, Livy treats of the wars with Macedonia and Antiochus, which contain 23 years. For the first five books of the fifth decade we are indebted to the researches of the moderns. They were found at Worms, in the year 1451. These are the remains of Livy's history. Freinshemius, with great industry and attention, has made an epitome of the Roman history, which is now incorporated with the remaining books of Livy.

LIV, in *Geography, a town of the duchy of Warsaw; 40 miles E. of Warsaw.*

LIXEME, a town of Prussia, in Oberland; 5 miles S.S.W. of Saalfeldt.

LIXIVIOUS, **LIXIVIAT**, or *Lixiviate*, in *Chemistry*, is understood of salts extracted from burnt vegetables by lotion.

Lixivious salts are the fixed salts of plants, &c. extracted by calcining the plants, or reducing them to ashes, and afterwards making a lixivium of those ashes with water.

Mr. Boyle observes, that the difference between lixivious and urinous salts consists in this, that the former change the dissolution of sublimite in common water into a yellow colour, which the latter do not. See **ALKALI** and **SALT**.

LIXIVIUM, **LEY**, or *Lees*, a liquor made by the infusion of wood-ashes; or, it denotes any alkaline solution, made by lixiviating pearl, or wood, or other ashes.

What is left after the evaporation of such a liquor is called a lixivious salt; such as all those are which are made by incineration.

Lixiviums are of use, not only in medicine, but also in bleaching, sugar-works, &c. See **BLEACHING**, **SUGAR**, and **POT-ASHES**.

LIXIVUM Martis, in *Medicine*, a form of medicine introduced into practice in the London Dispensatory. The manner of preparing it is to set the matter remaining in the retort after the subliming of the flores martis, in a damp place, where by means of the moisture of the air it will run into a liquor. See *Flores Martiales*, and *IRON*.

LIXIVUM Saponarium, *Soap-lee*, *Aqua kali puri*, P. L. 1787; *Liquor potassæ*, P. L. 1809; a liquor that has been much used in medicine in cases of the stone (see *LITHONTRIPTIC*); and when intended for this use, it is to be made something less strong than for the soap-boilers' use, and should be prepared in the following manner. Take Russia pot-ash, and quick-lime, of each an equal quantity; though pure alkaline salt requires commonly about twice its weight of quick-lime to render it completely caustic, which is known by the ley making no effervescence with acids: throw water on them in small quantities till the lime is slaked; then throw on more water, and stir the whole together, suffering it to stand for a day or two, that the salt of the ashes may be dissolved; after some time pour the liquor, filtered through paper, if needful, into another vessel. A true standard wine-pint of this liquor measured with the greatest exactness, ought to weigh just sixteen ounces troy. If it be found on trial to be heavier than this, for every drachm it exceeds that weight, an ounce and a half of water is to be added to each pint: but if it be lighter than this, it must be either boiled to this standard, or else poured upon fresh lime and ashes.

The makers of soft soap with us prepare their lees so much stronger than this, that to be reduced to this standard, it requires to be diluted with an equal quantity of fair water.

Quick-lime has the property of increasing considerably the causticity of all fixed alkalies, by absorbing their fixable air or gas. See *LIME*.

This caustic ley, evaporated to dryness, furnishes an alkaline salt exceedingly acid, which being melted in a crucible becomes what is called common *caustic*; because when it is applied to the skin, it makes an eschar, pierces it, and leaves an ulcer, the suppuration of which, when continued, is called an *issue*. Caustic alkali has not only much greater dissolving power, but it is also much more deliquescent, and attracts much more powerfully the moisture of the air, than ordinary alkali. This inconvenience is avoided by boiling down the soap ley only to one-fourth part, and then, while the liquor continues boiling, sprinkling in, by little and little, so much powdered quick-lime as will absorb it, so as to form a kind of paste.

The *liquor potassæ*, or solution of potash, of the last London Pharmacopœia, is prepared by dissolving a pound of subcarbonate of potash, *i. e.* the kali præparatum, P. L. 1787, or sal abstinii, sal tartari of P. L. 1745, in two pints of boiling distilled water; then adding three quarts of the water to a pound of lime newly prepared: mix the liquors while they are hot, stir them together, then set by the mixture in a covered vessel, and, after it has cooled, strain the solution through a cotton bag. If any diluted acid, dropped into the solution, occasion the extrication of bubbles of gas, more lime must be added, and the mixture strained again. This solution is more dense than water, and, when shaken, appears like oil.

LIXIVUM Tartari, the name given in the London Dispensatory of 1745 to the liquor called by most authors, as in P. L. 1720, *oil of tartar per deliquium*; in P. L. 1787, *aqua kali præparati*; and in P. L. 1809, *liquor potassæ subcarbonatis*. This is made of tartar, which is to be calcined to a whiteness, and then set in a damp place, where it will

liquify by the moisture of the air. The liquor thus procured is more pure than if the calcined tartar were dissolved directly in water.

In the last P. L. it is directed to be prepared by dissolving a pound of subcarbonate of potash in twelve fluid ounces of distilled water, and then straining the solution through paper. This solution will, in the ordinary state of the subcarbonate, amount to nearly 18 ounces in bulk.

LIXURI, in *Geography*, a town of the island of Cephalonia; 12 miles W. of Cephalonia.

LIZARD, in *Astronomy*. See *LACERTA*.

LIZARD, in *Natural History*. Lizards, in various parts of our work, referred to the article *LACERTA*, of which, in its proper place, we were disappointed, we shall now, it being the first opportunity afforded us after the omission, give an account of the whole genus, including a great variety of animals, which, although they possess many characters in common, yet exhibit considerable differences in their economy and habits, and also in their structure and external form.

For the anatomical description of this genus, we refer to the article *REPTILES*.

The genus *lacerta* has by some naturalists been regarded as a distinct order, and as such has been divided into several genera; but following the Linnæan arrangement, we shall consider the subject under the divisions or sections into which Linnæus separated the genus.

Dr. Shaw has thus enumerated them:

1. Crocodiles, furnished with strong scales.
2. Guanas, and other lizards, either with serrated or carinated backs and tails.
3. Cordyles, with denticulated, and sometimes spiny scales, either on the body or tail, or both.
4. Lizards proper, smooth, and the greater number furnished with broad square scales, or plates on the abdomen.
5. Chameleons, with granulated skin, large head, long missile tongue, and cylindric tail.
6. Geckos, with granulated or tuberculated skin, and lobated feet, with the toes lamellated beneath.
7. Scinks, with smooth, fish-like scales.
8. Salamanders, newts, or efts, with soft skins, some of which are water-lizards.
9. Snake-lizards, with extremely long bodies, very short legs, and minute feet.

This is an active tribe, and, with the exception of the aquatic animals, feeds on insects: the crocodiles have both jaws moveable, and the largest mouth of all animals: their body is covered with callonities: the chameleons have a prehensile tail; sit on trees; walk slowly and irregularly; have no teeth; eyes large, fixed in a wrinkled socket; tongue very long, worm-shaped, with which they draw in flies; head angular, covered with very thin lucid tubercles or scales.

The foregoing divisions, it is admitted, neither are nor can be perfectly precise, since species occur which may, with nearly equal propriety, be referred to either of the neighboring sections: on this account naturalists have not been agreed as to the exact number of species in each section, nor even as to the number of sections themselves. Dr. Shaw, as we have seen above, has separated the genus into nine sections; he has been followed by many other respectable writers, but in the last edition of Gmelin, as given by Dr. Turton, the genus is divided into eleven sections, which shall be given in their order.

Section A. Tail two-edged, divided into segments; tongue very short.

Species.

CROCODILUS, or Crocodile of the Nile; has a mailed head; nape carinate, tail above with two lateral crests.

This animal, as its name imports, is chiefly found in the river Nile, or on its banks. It sometimes arrives at a very great size: the common size of a full grown crocodile is from 18 to 25 feet long, though some have been seen that measure full forty feet in length. The colour of the upper part is a blackish-brown, but beneath it is of a yellowish-white. The upper parts of the legs and sides are varied with deep yellow, and in some parts tinged with green. The opening of the mouth is of vast extent, and both jaws are furnished with numerous sharp-pointed teeth; those in the middle part of the jaw being largest, and resembling the canine teeth of viviparous animals. The external openings of the ears are placed on the top of the head, above the eyes, and the eyes themselves are furnished with a nictitating membrane, similar to that of birds. The legs are short, strong, and muscular. The tail is long, compressed on the sides, and furnished above with an upright process, formed by the gradual approach of two elevated crests, which proceed from the lower part of the back. The upper part of the body of the crocodile is covered with a strong armour, which in its structure exhibits the appearance of the most curious carved work, and is indeed a fine piece of mechanism. The crocodile deposits its eggs in the sand or mud on the banks of the rivers which it inhabits, and as soon as the young are hatched, they proceed to the water. The crocodile is a native of Asia and Africa, but it seems more common in the latter than in the former country. It inhabits only large rivers, and lives chiefly on fish, but being extremely voracious, it seizes any other animal that comes within its reach. The crocodile has long been regarded as one of the most formidable animals of the countries in which it is found, but some late travellers seem to have entertained a less formidable opinion of them. M. Denon, speaking of the French army in Egypt, says that the soldiers and himself bathed daily in the Nile, and yet they were never once attacked by them, nor did they ever meet with a single crocodile at a distance from the water. Hence he inferred that they find in the river a sufficient quantity of easily procurable food, which they digest slowly, being, like the lizard and serpent, cold blooded, and of an inactive stomach. "Besides," says the traveller, "having in the Egyptian part of the Nile no enemies but each other and man, they would be truly formidable, if, covered as they are with an almost impenetrable defensive armour, they were skilful and alert in making use of those means which nature has given them for attack." He farther adds, that they saw three crocodiles, one of which was nearly twenty-five feet in length; they were all asleep, so that they could approach them within about twenty yards, and had an opportunity of distinguishing them very accurately. He says, that in that position they resembled dismounted cannon: he fired on one, the ball struck him and rebounded from his scales. He made a leap of ten feet, and dived into the river.

In the large rivers of Africa, and in certain parts of those rivers, they may be seen in vast shoals swimming together, where they exhibit the appearance of floating timber. A variety of the common crocodile has been found in the river Senegal, it has a longer snout, and is almost entirely black. It is very swift, voracious, and of amazing strength; it roars hideously; devours every thing that comes in its way; swallows stones to prevent hunger, and cannot be killed by a musket ball unless struck on the belly: it seldom moves but in a straight line, and may accordingly be

avoided: the female lays her eggs in the sand, which are not much larger than those of a goose.

GANGETICA, or Gangetic crocodile. This animal has long, roundish, or sub-cylindric jaws; its tail on the upper side has two crests running into one.

This species is found in the Ganges, where it is nearly equal in size to the common crocodile. In this the structure of the snout is very remarkable, it being nearly three times as long as the head. The eyes are extremely prominent, and it is said they are so constructed, that they may be raised above the water, when the rest of the body is under the surface, by which the animal is enabled to see its prey either on the surface of the water, or on the banks of rivers. In the general form and colour of the body and limbs, this species resembles the common crocodile. In the British Museum is a specimen of this creature, measuring eighteen feet in length.

ALLIGATOR. The head of this animal is flat, imbricate; nape naked; tail above with two rough lateral lines.

It inhabits the middle parts of America, is less than a crocodile, but resembles it in habits and voracity. The largest in size, and the greatest numbers of alligators, inhabit the torrid zone, nevertheless the continent ten degrees more north abounds with them, particularly as far as the river Neus in North Carolina. In the latitude 33, which answers to the northernmost parts of Africa, where they are likewise found, they frequent not only salt rivers near the sea, but streams of fresh water in the upper parts of the country, and in lakes of salt and fresh waters, on the banks of which they lie lurking among the reeds to surprise cattle and other animals. They are found in Jamaica, and many parts of the continent, full 20 feet in length. But we are told they cannot be more formidable in their aspect than terrible in their nature, sparing neither man nor beast which come within their reach, pulling them under water and drowning them, in order that they may with greater facility, and without a struggle or resistance, devour them. They subsist chiefly on fish, but as Providence, for the preservation, or to prevent the extinction of defenceless creatures, has in many instances restrained the devouring appetites of voracious animals, by some certain impediments; so this destructive monster can proceed only in a straight forward direction, and is consequently disabled from turning with that agility requisite to catch his prey by pursuit; therefore alligators do it by surprise in the water, as well as by land: they have the power of deceiving and deceiving their prey, by a sagacity peculiar to themselves, as well as by the outer form and colour of their body, which on land resembles a log or tree, and in the water lies floating on the surface, and has the like appearance, by which, and their silent artifice, fish, fowl, and turtle, are lured into their grasp, and suddenly caught and devoured. Carnivorous animals get their food with more difficulty, and less certainty than those which subsist on vegetable substances, and are frequently obliged to fast long, which a slow digestion enables them to endure. Reptiles particularly, by swallowing whole what they eat, can live long without food. Alligators swallow stones and wood, to distend the stomach and prevent its contraction by emptiness. They lay a great number of eggs at one time on sandy banks of rivers and lakes, which are hatched by the heat of the sun, without any care of the parent. The young, as soon as they are disengaged from the shell, run to the water by a natural instinct, and shift for themselves, and while young they serve as a prey not only to ravenous fish of other tribes, but to their own species. In South Carolina they are numerous, but smaller than those towards the equator, but they attack men and cattle, and

L I Z A R D.

are great devourers of the race of swine. In Carolina they lie torpid during the winter in caverns and hollows in the banks of the rivers, and at their coming out in the spring make a hideous bellowing noise. According to Catesby, in his history of Carolina, some parts of alligators are reckoned very delicious food by the Indians. They deposit their eggs at two or three different periods, and more than twenty of them at each laying. They have been observed to raise a small hillock near the banks of the river, and after hollowing it out in the middle, to collect a quantity of leaves and other vegetable matters, in which they deposit their eggs. Both the alligator and crocodile are supposed to be long lived animals. It has been thought the crocodile, or some of the species, was the leviathan mentioned in the book of Job, chiefly, perhaps, because the description of this monster does not sufficiently correspond with the general structure of the whale; nevertheless, the leviathan there mentioned will correspond full as little with any of the species of the crocodile now known as with the whale, and it is more probable, that, like the mammoth, the leviathan of the scriptures is not now to be found on the face of the earth.

Section B.—The animals of this section have the body covered with carinate scales.

Species.

CAUDIVERBERA, or flat-tailed lizard, is found in Peru and Chili, and is about twelve or fifteen inches long. The tail is depressed, flat, wing-cleft; feet palmate. The body is inclining to blue; scales very minute; head convex, oblong; eyes very large, yellow; nostrils wide, with a fleshy edge; mouth large, teeth minute, hooked in a double series; tongue thick, broad, red; chin with a dilatable pouch; crest running down the back from the front to the tip of the tail, undulate at the edge; feet five-toed, with a cartilage instead of nails.

DRACENA, or large long-tailed lizard, with a smooth body, and tail denticulated along the upper part. The body is of a deep chestnut-colour; the scales are very minute; the legs tessellate, with saffron and white. It inhabits America, and has been named the large American cordylus, and has sometimes been confounded with the caudiverbera just noticed.

It is a native of several parts of South America, and of some of the Indian islands, and is regarded, in some countries in which it is found, as a great delicacy. The head is small, and rather elegantly formed, the snout tapering in such a manner as to bear a resemblance to that of an Italian grey-hound; the teeth are small and numerous, and the tongue forked; the proportions of the neck and limbs are elegant, though strong; and the body is moderately thick; the tail is of great length. The whole animal is smooth, or destitute of prominences on the skin, which is covered with small, ovate, and, in some parts, slightly subquadrate scales, largest on the outside of the limbs, the back, and the abdomen; along the upper edge of the tail runs a continued series of short triangular denticulations; the feet are moderately strong, and the toes are armed with sharp crooked claws.

Dr. Shaw mentions a variety, of which there was a specimen in the Leverian Museum, which differs in being of a pale brown colour, variegated on the body and tail by several deep-brown transverse bands, among which, as also on the abdomen and limbs, are interspersed many smaller variegations, and spots of a similar colour.

BIMACULATA, or Pennsylvanian lizard, has a tail carinate, notched, twice as long as the body, all the toes, of which

there are five on each foot, are lobate. The colour of its body is greenish-blue, mostly spotted with black; the shoulders with two large spots. It is found in the woods of St. Eustatius and Pennsylvania, and lives in holes, gutters, and hollow trees; makes a hissing noise, and deposits its eggs in the earth.

MONITOR, or monitor lizard, is one of the largest of the lizard tribe; it measures sometimes from four to five feet. Its colour is black; tail very long, compressed, carinated; body marked with transverse rows of white, ocellated.

This is a very beautiful animal. The head is small; the snout gradually tapers; the limbs are slender; and the tail, which is laterally compressed, gradually decreases towards the extremity. As a whole, the form is slender and elegant; though the colours are simple, they are so disposed as to produce an agreeable effect. It is a native of South America, inhabiting woody and marshy places. If credit may be given to reports of authors, who pretend to have studied its habits and characters with much accuracy, its disposition is as gentle as its appearance is beautiful. It has even gained the title of monitor salvaguarda, &c. from its pretended attachment to the human race: it has been confidently affirmed, that it warns mankind of the approach of the alligator by a loud and shrill whistle.

There is a variety of this animal mentioned by White, in his "Journal of a Voyage to New South Wales;" but in Gmelin's edition of the "Systema Naturæ," it is given as a distinct species, under the name of

VARIA, or variegated lizard. Though there is a great resemblance between this and the monitor; yet there are certain points of difference in its colour, and variegations that will justify its introduction as a separate species. The tail is long, carinate; body blackish, transversely variegated with yellow spots and marks.

It is found in New Holland. The markings on the body, instead of the general ocellated pattern of the preceding, consist of rounded, or slightly subangular spots and variegations: the limbs, as in the monitor lizard, are marked with numerous bands and spots, and the tail is banded; the claws are very large and strong.

BICARINATA, or bicarinated lizard, has a tail of moderate length; four rows of strong carinated scales on the back. The head is small; the mouth very wide in proportion, and the snout somewhat sharp. It is of a reddish-brown colour, tinged in some parts with various shades of green.

In its general habit, this species bears a resemblance to a small crocodile, on account of the hard tuberculated and carinated scales, on the upper parts of the body, two rows of which are more prominent than the rest, and extend from the upper part of the back to the tail, where they coalesce and form a serrated crest to the extremity. It is a native of South America, where it is sometimes used as food, and its eggs are highly esteemed. Its haunts are woody and marshy regions: it is fond of water; and one kept some time by M. de la Borde, often continued in it for several hours together, hiding itself when disturbed or affrighted, but it seemed delighted in coming out and basking in the direct and strong rays of the sun.

A lizard, known under the name of *ignarica*, a native of Brazil, is regarded as a variety of the species just described, differing only in colour, which is darker, and the claws, which are shorter, but, like it, there is some resemblance between it and the crocodile: it readily climbs trees.

CORDYLUS, or Cordyle lizard, has a smooth body, short tail that is verticillated with denticulated scales. This species is sometimes blue, and sometimes of a livid-brown, and the

total

L I Z A R D.

total length is not above ten or eleven inches. The scales which cover the body are of an oblong form, and the tail is verticillated with rows of large scales.

Section C. Back and tail, or the whole body, covered with denticulate or sharp-pointed scales.

Species.

PELLUMA, or Pelluma lizard, has a long tail, and verticillated with rhomboidal scales. It is about two feet in its total length, and is distinguished on the upper parts of its body by a beautiful variety of green, yellow, blue, and black colours. The under parts of the body are of a glossy yellowish-green: it is a native of Chili, and lives under ground; the inhabitants of that country make its skin into pouches. Its feet are five-toed, and its claws very strong.

STELLIO, or rough lizard, has a verticillated tail, with denticulated scales: the body and head are muricated.

This species, as its English name implies, is remarkable for the unusually rough appearance of its whole upper surface; both body, limbs, and tail being covered with pointed scales, projecting here and there to a considerable distance beyond the surface. The general colour of the animal is a pale blueish-brown, with a few deeper and lighter transverse variegations. It is not above eight or nine inches in length. It is a native of many parts of Africa. Dr. Shaw, in speaking of this species, says, "it may be observed that the lizard, which was probably termed *Stellio* by the ancients, from its being marked with spots resembling stars, seems at present unknown. It is, however, observable, that in one of Seba's plates a species occurs, which is actually marked with well-defined or regular star-shaped spots." Some naturalists consider the lizards called geckos as the true *stelliones*.

MAURITANICA, or Moorish lizard, is characterized by a subverticillate tail, muricate, short, smooth at the tip, body above muricate, toes unarmed, lamellate beneath.

This is one variety: the second is distinguished by a verticillate tail; and the third by having a prickly body. It is found in Mauritania, and in some parts of India. The body is lurid, the upper part has protuberances, the lower is smooth; scales are very minute; tail shorter than the body, from the base to the middle rough, with six rows of spines, thence to the tip smooth.

AZUREA, Azure lizard. Tail verticillate, short with mucronate scales.

This is the *elegantissima* of Seba. The colour, in its natural state, seems to be an elegant pale blue, fasciated on the body and tail with several transverse, and alternate bands either of black or very deep blue; but this is said to be most conspicuous in the smaller specimens or varieties. It is sometimes only a few inches long. The larger variety has a deep chestnut band on the shoulders. The smaller variety is a native of some parts of Africa; the larger of South America.

ANGULATA, or Angulated lizard, has a long and hexagonal tail, and is furnished with carinated and mucronated scales. This is a small species, having a tail longer than the body. The colour is of a dusky brown. Beneath the throat there are two rounded scales. The tail is longer than the body, and strongly marked with longitudinal ridges. It is a native of America.

ORBICULARIS, or Orbicular lizard, has a brown body; the tail is short, scales muricated. Both body and tail are round. The colour is of a dusky brown, variegated with different shades; the body is large, and in some respects it

resembles a toad. It is a rare species, and is a native of South America, particularly in New Spain.

BASILISCUS; Basilisk lizard. Tail round; dorsal fin radiate; hind-head crested. The basilisk is about eighteen inches long, of a pale ash-brown colour, with some darker variegations about the upper part of the body. In the young animal, the dorsal or caudal process, and the pointed occipital crest, are less distinct.

The basilisk is chiefly a native of South America. It resides principally among trees, and its food is insects. It is active, and by means of its dorsal crest or fin, it is enabled to spring from tree to tree. It can swim with great ease. It has a very formidable appearance, but is quite harmless. In the poetical descriptions of the ancients, it was considered to be the most malignant of all poisonous animals, even its look was regarded as fatal. The terrific glance of the basilisk in the African deserts, according to Lucan, obliged the rest of the poisonous tribe to keep at a distance.

PRINCIPALIS; Smooth-crested lizard. The tail of the species is subcarinate; crest on the throat very entire, back smooth. It is of a slender form, and small, rarely exceeding eight or nine inches in length, including both body and tail. The colour is blue, the head small, and the snout taper. It is a native of South America.

PLATURA; Broad-mailed lizard. Colour grey-brown, paler beneath; body rough; tail depressed, lanceolated, and spiny on the margin. This species is from four to six inches long; it is distinguished by the singular form of its tail. The feet are pentadactylous; the toes slender, and the claws curved. It is found in New Holland.

Section D. Back ciliate, toothed or crested; head covered with callonities.

Species.

IGUANA; Common or great American Guana. This species has a long round tail; back serrated; the throat crest denticulated. This, of all the lizard tribe, is the most peculiar form, and grows to a considerable size. It is sometimes three, four, or five feet long. The general colour is green, shaded with brown. The back is strongly serrated, which, as well as the denticulations of the pouch at the throat, gives it a formidable appearance.

It is a native of the West Indies, and some parts of the continent of America. It frequents rocky and woody places, and feeds chiefly on insects and vegetables. It is easily tamed, and follows the human race like a dog; it is caught by a noose thrown over its head; the flesh is reckoned a great delicacy: the general colour is green, but variously tinged in various animals: it has the power of inflating the throat pouch to a very large size.

According to Catesby the animals of this species are of various sizes, from two to five feet in length; their mouths are furnished with exceedingly small teeth, but their jaw is armed with a long beak, with which they bite with great strength. They inhabit warm countries only, and are rarely met with any where north or south of the tropics. Many of the Bahama islands abound with them, where they nestle in hollow trees and rocks. Guanas make a considerable part of the subsistence of the inhabitants of the Bahama islands, for which purpose they visit many remote islands in their flocks to catch them, which they do by dogs trained for the purpose. Guanas feed on vegetables and fruit, particularly on a kind of fungus growing at the roots of trees, and on the fruits of the anona. Their flesh is easy of digestion, but is thought not to agree with constitutions labouring under a particular disease.

Though

Though guanas are not amphibious, they are said to keep under water above an hour. When they swim they make no use of their feet, but clap them close to their body, and guide themselves with their tails. They are so impatient of cold, that they rarely appear out of their holes except when the sun shines strongly.

The *horned* guana is a variety of the iguana, and is nearly the same in size and general proportions; the back is serrated, and the form of the scales is the same. It wants, however, the throat pouch, and there are in front of the head, between the eyes and nostrils, large scaly tubercles, behind which there is a bony conical process, which is covered with a single scale. It is a native of St. Domingo, where it is common.

CALOTES; Galeot lizard. Tail long and round; back denticated on the fore part, and the head on the hind part.

The animals of this species seldom exceed a foot and a half in length, from the tip of the nose to the extremity of the tail, but in other respects the calotes resembles the common guana. It wants the pouch, and in its place there is only a slight enlargement of the throat: the colour is commonly of an elegant bright blue, variegated with broad, irregular, white, transverse bands on each side of the body and tail. The limbs are slender, and this is particularly the case with the toes. It is a native of the warmer regions of Africa, Asia, and many of the Indian islands. It is very common in Ceylon. It is said to be found in Spain, where it wanders about the tops of houses in search of spiders.

There is a variety, of which the body above is livid, and beneath green; and a second, the neck of which is covered with broad obtuse prickles.

SUPERCILIOSA; Fringed lizard. Tail carinated; back and eye-brows ciliated, with upright lanceolated scales. It inhabits South America and India.

The general appearance of this species bears some resemblance to the guana, and still more to the variety described as the horned guana, in having the appearance of a pair of sharp-pointed horn-like processes above and beyond each eye; between these are placed some aculeated scales.

SCUTATA; Shielded lizard. Tail sub-compressed, moderately long; dorsal future toothed; hind-head with two sharp scales. It inhabits Asia. This species is distinguished from the fringed lizard by having a proportionably larger head, and a row of scales more elevated than the rest, passing over each eye; and from these a ridge is continued towards the back, in form of a denticulated crest to the beginning of the tail. The body is covered with small acuminate scales; the limbs and tail with larger ones. This is a native of Ceylon.

AMBOINENSIS; the Amboina lizard. Tail compressed, long, with a radiate fin; dorsal future toothed. This species, which sometimes grows to the length of three feet, is distinguished by the singularity of its appearance, and the beauty of its colours. The head and neck are green, and variegated with white transverse undulations. The back and tail are brown, with a shade of purple. The sides and belly are greyish, or pale brown, the head is tuberculated above, and covered with roundish scales; the mouth is wide, and the teeth are sharp and numerous.

It is a native of the East Indies, but is found most frequently in the island of Amboina, frequenting the neighbourhood of rivers and other fresh waters. It is often seen on the banks of rising grounds, and on low shrubs which grow near the water. Whenever it is disturbed by the approach of men or other animals, it plunges into the nearest water and conceals itself beneath the rocks, or stones under the banks. It may be easily taken, as it does not attempt

to defend itself, but seems, in some measure, stupified. Like other species of this numerous tribe, it deposits its eggs in the sand, on the banks of the rivers which it frequents. The eggs, while in the body of the animal, are disposed in two long groups or clusters, and are of a yellow colour; but when excluded, they are white and oblong.

This lizard appears in some degree to form a connecting link between the guana and the basilisk. The male and female differ considerably in size and in the distribution of their colours; the female being of a more obscure tinge than the male, and having but little appearance of the crest or process on the tail. It has been dissected, and a small triangular heart found within it: an oblong liver, with a round gall-bladder; small reddish lungs, slightly tinged with lead-colour; a narrow, whitish stomach, coated, or enveloped in fat, and large intestines, in which were discovered the berries and seeds of certain aquatic shrubs, together with some small semi-transparent pebbles, and a kind of worms not unlike millepedes. There was a fine specimen of this species in the Museum of the late Mr. John Hunter.

AGAMA; American galeot. Tail long, round; the upper part of the neck, and the back of the head, are aculeated; scales of the hind head reversed. This species resembles, in some respects, the calotes: but it wants the strong serratures on the back, instead of which it has only a small denticulated carina. The head is proportionally larger, and on the back part it is furnished with sharp-pointed scales, some of which are reversed at the extremities. The colour is brownish, and variously clouded. In the male, the crest on the back is composed of longer spines, and extends to the lower part. It is found in different parts of South America and in the West Indian islands.

There is a variety of this species named the muricated lizard. The tail is long, round; body greyish; scales carinated and sharp pointed. This lizard measures a foot or more in length. The want of the reverse scales on the back part of the head constitutes the principal difference between this and the calotes. It is found in New South Wales.

UMBRA; Clouded lizard. Tail round, long; nape sub-crested; hind-head callous; back striated. This is found in the southern parts of America: the body is clouded; scales keeled, and daggered at the tip, head more obtuse and round than others of its tribe: the *callus* on the hind part of the head is large and naked: under the throat is a deep fold.

MARMOREA; Marbled lizard. Tail round, long; throat subcrested, dentate on the fore-part; back smooth. It is found in America, and also in Spain. Its body is compressed; tail streaked, and the claws are black above.

CRISTATA; Crested lizard. Tail lanced, short, pinnate; back crested; body porous, naked. It is of a reddish-brown with lead-colour spots; crest reaching from the head to the tail; the head is very thick, obtuse; snout broad; feet cleft; four toes on the front feet and five on the hinder ones; tail bordered on each side with a membrane.

Section E. Body naked; feet unarmed; fore-feet four-toed.

Species.

AMERICANA. Tail lanceolate, middle-sized; back fringed; belly spotted with yellow; it is only about four or five inches long, and is found in America. The fore-part of the head is rounded; snout broad; body dusky blueish, beneath yellow spotted with black, sides pale ochreous legs

legs without blueish, within yellow; a fringe extending from the head to the tip of the tail.

PALUSTRIS; Warty newt. Body blackish; sides speckled with white; belly orange, with irregular black spots. This species is small, and bears a considerable resemblance to the salamander. It is from five to six inches in length. The tail is flat, with thin sharp edges, and terminating in a point; on each side of it in the male there is a silvery white broad band, accompanied with a blueish tinge. This stripe and the dorsal crest are sometimes wanting in the female.

It is found in many parts of Europe, but is rarely seen in Britain. It frequents stagnant waters in cool and shady places, and lives entirely on insects. It is said to be entirely harmless with regard to larger animals, but that a fluid is exuded from its skin which seems to act as a poison on small animals.

LACUSTRIS; Fenny newt. Of this species there are several varieties. 1. Black; tail lanceolate, middle-sized. 2. Much larger; spotted with black. 3. Variegated black and yellow, and spotted with black. 4. Tuberculate; chin speckled; belly spotted; tip of the tail red. 5. Tuberculate; belly saffron colour. 6. Head round; black spotted with pale yellow. 7. Black with whitish bands. 8. Black; beneath dotted with white. This species, which is found in many parts of the world, is very destructive of fish.

AQUATICA; Water-newt. Tail roundish, middle-sized; there are likewise varieties; brown or yellowish; and one with a dorsal line dotted with white and black; the first is found in many parts of Europe; the second inhabits France; and the third in Germany.

It lives in pools, ditches, and stagnant waters, and is killed in three minutes if salt be sprinkled upon it. The body is spongy, blackish dotted with black; chin rough; back sub-crested; tail smooth, speckled with a longitudinal white stripe on each side.

The general length of this species is from three to four inches. The male is readily distinguished from the female by a conspicuous dorsal crest, which is more elevated, and more regularly sinuated than that of the palustris. The broad crest is very transparent, and when examined by a magnifying-glass shews the ramifications of the blood-vessels and the circulation of the blood. In the female the dorsal crest is nearly wanting. The fore-feet are tetradactylous; but the hind-feet have five toes, and in all, the claws are wanting; but with regard to colour, the breadth of the tail, and that of the toes, water-newts differ at different seasons of the year, in different states of the weather, and sometimes a considerable variation is observed even in the course of the same day.

This species is very common in stagnant waters. It breeds early in the spring, and deposits small oblong strings or clusters of spawn. The ova are of a kidney shape, and the larvæ are ready formed, and may be seen active and sporting before they leave the gluten. They extricate themselves in about ten days, and when they are first excluded, the branchial fins are distinctly seen, and soon after their fore-legs appear. In a fortnight the hind-legs are visible, and in about four or five months the branchial fins become obliterated, and the animal assumes a perfect form. In the larva state, the animal has the appearance of a small fish. It casts its skin, which may be found floating on the waters which it frequents, and is sometimes so perfect as to represent the whole form of the complete animal. The reproductive power of this species of lizard has been noticed as a very striking circumstance in natural history. They have been known to have their legs, tails, and even their eyes

restored after they have been destroyed. It has also been ascertained that water-newts have been completely enclosed in a mass of solid ice, in which they have remained several weeks, and yet upon a thaw the little animals have been restored to their former health and vigour. We may mention in connection with this a species described by Dr. Shaw, denominated the

LEVERIAN Water newt; of which there was a good specimen in the Leverian museum. The total length of this is $17\frac{1}{2}$ inches, and its tail is about six or seven inches of it. The head is flattened, the mouth moderately wide, and the upper jaw is furnished in front with two concentric rows of numerous, small, bristly teeth. The under jaw has only a single row. The eyes are small, round, situated on each side of the front of the head, so that they are remote from each other. The colour is pale brown, marked with darker variegations. The legs are about an inch in length, and they are all furnished, along their whole length behind with a dilated skin or crest. The tail is like that of a common water-newt, but shorter and not so deeply finned.

SALAMANDRA; Salamander. The specific character of this animal is, colour black, spotted with golden yellow; tail round, and of moderate length. Of this species there are, besides the one described, some entirely black; some brown; some white; and some small, brown; with a tail in some degree compressed. The salamander, so long the subject of popular error, and of which so many idle tales have been recited by the more ancient naturalists, is an inhabitant of many parts of Germany, Italy, France, &c. but has not been discovered in England. It delights in moist and shady places, and during winter conceals itself in recesses under ground, in the cavities of old walls, or about the roots of old trees. It is easily distinguishable by its fine colours; being of a deep shining black, variegated with large, irregular patches of bright orange-yellow; which on each side the back are commonly so disposed, as to form a pair of interrupted longitudinal stripes; on each side of the back of the head is situated a pair of large tubercles, which are in reality the parotid glands, that are protuberant not only in this and other species of the *Lacerta* genus, but in a remarkable manner in the *Rana* or frog tribe. See *RANA*.

These parts, as well as the back and sides of the body, are beset in the salamander with several large open pores, through which a peculiar fluid is exuded, serving to lubricate the skin, and which, on any sudden irritation, is secreted in a more sudden and copious manner under the form of a white gluten of a slightly acriminous nature; and from the readiness with which the animal, when disturbed, appears to evacuate it, has arisen the long continued popular error of the salamanders being enabled to live uninjured in the fire, which it has been supposed capable of extinguishing by its natural coldness and moisture; the real fact is this, that like the other cold and glutinous animals, as snails, frogs, &c. it is not quite so instantaneously destroyed by the force of fire as an animal of a drier nature would be. The general length of the salamander is about seven inches, though it sometimes arrives at a much larger size. It lives principally on insects, small snails, &c.; its tongue is not by any means formed to catch these in a sudden manner, being short, broad, and in some degree confined, so as not to be darted out with celerity. It is capable of living in water as well as on the land, and is found occasionally in stagnant pools. Its pace is slow, and its habits torpid. The salamander is viviparous, and the young are produced perfectly formed, in the same way as the viper. It is said to retire into the water to deposit its young, the number of which at one birth amounts to 30 or 40; when they are first excluded, they are furnished with branchial

L I Z A R D.

chial fins on each side the neck; these are but temporary organs, and are afterwards obliterated like those of the tadpole.

It has been thought that the salamander was a venomous animal, and that its poison is of so malignant a nature, as scarcely to admit of any remedy. Later observations and experiments have ascertained that it is perfectly innocent, and although the fluid secreted from the skin may be noxious to smaller animals, it is incapable of inflicting either wound or poison on any large animal.

STRUMOSA; Strumous lizard. Tail round, long; breast gibbous, projecting forward. This is of a small size, has no serratures, but is furnished with a large flat crest at the throat, of a pale red colour; the other parts of the animal are of a pale bluish-grey, with some slight shades of a more dusky hue. The limbs are slender. It is a native of South America.

VITTATA; Forked lizard. The tail of this species is round, long; body brown with a white dorsal fillet, forked over the head. It inhabits India; it does not exceed six or seven inches in length; the head is large in proportion to the body, the toes are lamellated beneath; terminated by curved claws. The upper surface is covered with extremely small tubercles, which are so minute as scarcely to be perceptible.

TURKICA; the Turkish lizard. Tail subverticillate, middle-sized; body grey, and a little warty. It inhabits the East. Its body is dusted with brown spots, unequal, and as if sprinkled with scarcely visible warts; the tail is about the length of the body.

RAPICAUDA; Turnip-tailed lizard. Tail turbinate; ears concave. This species is found in several of the American islands; the body is white, spotted with brown; warts small, thickly sprinkled; claws hollowed in the middle underneath.

GECKO; Common Gecko lizard. Tail round, middle-sized; toes a little clawed; ears concave. This animal is said to have received its name from the peculiar sound of its voice, which bears a resemblance to that word when uttered in a shrill tone. It is twelve or fourteen inches long, and is accordingly ranked among the middle-sized animals of the lizard tribe; but it is thicker and stronger than the greater part of lizards. Its head is flattish, somewhat triangular, and large, with a covering of minute scales; its mouth is wide, eyes large, teeth small, and its tongue is broad and flat. The usual colour of the gecko is brown, with some irregular dusky or bluish variegations, but this colour becomes more brilliant in warmer regions.

It inhabits India, Arabia, Egypt, and the warmer parts of Europe; it frequents houses in summer, but is seldom seen in the winter; makes a noise like a weasel; is tame, and when frightened will run into houses for shelter; it emits a poisonous fluid from the lamellæ beneath its feet, which, if smeared over fruit, or other articles of food it has run over, causes a violent colic in those who happen to eat them; it frequently stands in an erect posture on its hind-feet; from the peculiar structure of its feet the animal is enabled to attach itself to the smoothest surfaces.

There is a variety of this species denominated *Tokai*, described by the Jesuit missionaries sent by Lewis XIV. to Siam; of which the body is covered above by a granulated skin, varied with red and blue undulations; the belly is of an ash colour, and interspersed with red spots; the head is large and triangular. It is a native of Siam, and is regarded as a poisonous animal. Bontius, in his History of Java, appears to describe one of a similar kind, under the name of the Indian salamander. It is called *Gecko*, on account of its

shrill cry. It is about a foot long, and its colour is fea-green, spotted with red, the head is large and toad-like; the eyes are large and extremely protuberant. It is said that the Javanese hold up the animal by the tail to make it discharge saliva from the mouth, which they collect and preserve for the purpose of poisoning their arrows.

GEITJE. Tail lanceolate, middle-sized; fore-feet with four toes; this species is found at the Cape of Good Hope. It is called by some naturalists *Sparmanniana*, on account of its having been first described by Sparmann. Its colour on the upper parts is a variegation of darker and lighter shades, and on the under parts it is whitish. It is looked on as a poisonous animal, and is supposed to secrete from its pores a fluid which produces tumours and even gangrenes, that are sometimes cured by the application of citron juice, but which, if long neglected, are very productive of dangerous symptoms.

Section G. The animals in this division have feet with five toes; some of which are connected; the tail is round, short, incurved.

Species.

CHAMÆLEON. Three varieties are mentioned in the *Système Naturel*, of which the specific character of the first is, body cinereous; head flat; of the second the body is white; and of the third the head is very large.

The chamæleon inhabits India and New Spain; it lives chiefly in trees: from the anatomical description, the lungs are large, and capable of being inflated to an enormous size by the animal; the eyes are so moveable that the creature can look in different directions at the same time; the pupil has a golden glare, and frequently changes its colour.

Few animals have been so much celebrated as the chamæleon, which, it was long believed, has the power of changing its colour at pleasure, and of assimilating it to that of any particular object or situation. This, however, is not the real state of the case; the change of colour which the animal exhibits varies in degree according to the circumstances of health, temperature of the weather, and other causes, and consists chiefly in an alteration of shades from the natural greenish or bluish-grey of the skin into pale yellowish, with irregular spots of dull red. Another erroneous assertion with regard to the chamæleon was, that it could subsist on air. This arose from the long abstinence which it is known capable of enduring.

The length of the chamæleon is about ten inches, but including the tail, it is nearly double that length. The skin on every part of the animal is granulated. There are five toes on each foot, two and three of which are united by a common skin as far as the claws. The structure of the tongue is peculiar; it is very long, and furnished with a dilated somewhat tubular tip, by which means it is enabled easily to seize insects, by darting it out and securing them on the tip. It is found in many parts of the world, and particularly in India and Africa; and has been seen in the warmer parts of Spain and Portugal. For a farther account of this animal, see **CHAMÆLEON**.

AFRICANA; or African lizard. Black; head carinate; it inhabits the northern parts of Africa and Spain; in its habits it resembles the chamæleon; the protuberant parts are all white.

PUMILLA; Dwarf lizard. Sides bluish, with two yellowish lines; it is found at the Cape of Good Hope. In this species the head is somewhat flatter than that of the *Africana*, but still elevated in the middle, and edged on each side with a denticulated margin. The *Africana* and the *Pumilla* have been regarded, by some naturalists, as varieties of the same species.

Section H. The animals of this division have their collar double; and square abdominal scales.

Species.

AMIVA; the blue lizard. Tail verticillate, long; abdominal scales thirty; collar beneath with a double wrinkle. It inhabits America, but occurs in Africa and Asia. The abdominal scales are in eight rows.

TILIGUERTA. Tail verticillate; twice as long as the body, abdominal scales eighty. It is about seven or eight inches long, and is found during the whole year in the fields and meadows of Sardinia.

AGTUS; Sealy or green lizard. Tail long, verticillate, with sharp scales; collar is sealy beneath. This elegant species, which is found in all the warmer parts of Europe, varies in length from fifteen inches to two feet. It is the most beautiful of all the European lacertæ, exhibiting a rich and varied mixture of darker and lighter green, interspersed with specks and marks of yellow, brown, blackish, and even sometimes red. The head is commonly of a more uniform green than the rest of the body; the under part of the animal, both on the body and limbs, is of a pale blue-green cast; the head is covered with large angular scales; the rest of the upper parts with very small ovate ones; the tail, which is commonly longer than the body, is marked with numerous rings of oblong-square scales, slightly bifid at their extremities; beneath the throat is a kind of collar, formed by a row of scales of much larger size than the rest: the abdomen is covered, down its whole length, with six rows of broad transverse plates, and the under surface of the limbs is also covered with similar scales; along the inside of the thighs runs a row of papille or tubercles, about thirteen in number, which, in this and other species, probably assist the animal in climbing or clinging to the stems and branches of vegetables; the tongue is moderately long, and formed to enable the animal to retain and swallow its prey, which consists chiefly of insects, small worms, &c.

This species is a native of all the warmer parts of Europe. It is found in gardens, about and in crevices of warm walls, buildings, &c. It is, as its name imports, a very active animal, and pursues its prey, which consists of insects, with great celerity. When it is caught it may be tamed, and it soon becomes familiar.

It appears to run into numerous varieties both as to size and colour; but in them all the particular characteristics of the species are easily ascertained. Besides the one already described, we have in the Syst. Nat. the following varieties: 1. One in which the lowest scales of the collar are loose. 2. That in which the skin is very thin and of a brown colour. 3. Body with eye-like spots. 4. Brown; on each side a series of indistinct spots. 5. Sides brown; back tawny. 6. Blueish; each side a triple row of ocellate spots. 7. Green speckled with brown; collar tawny. 8. Blue; head white; back longitudinally striate; hind-legs spotted. 9. Blue; the sides speckled with white.

The 8th, found in America, is described as innocent, active, elegant, living in dry meadows, walls, and rocks. Some of the animals of this species have been used as a medicine, and have been supposed to possess peculiar virtues in leprosy and other similar cases.

SEPIA; the eft. Tail verticillate, long; lateral future of the scales square.

This is a small species, and is easily known from the thin length of the body, and its long slender tail. There are three varieties, the first answers to the specific character, being the second is variegated with chestnut; head varied with black and white; the third is black-blue, marbled

with confluent white bands mixed with round spots. It inhabits southern countries. The body is covered above and beneath with truncate scales in eight rows, forming lateral and longitudinal streaks, belly flat; tail with about 50 whorls, half as long again as the body; legs short, distant, but well formed for running. See EFT.

VELOX; Swift lizard. Tail verticillate, longish; collar beneath sealy, body above cinereous, varied with five longitudinal paler streaks and brown dots; sides spotted with black, dotted with blueish.

This species is found in Siberia, particularly in the sultry desert places about the lake of Inderfkién; it wanders among the rocks, and is exceedingly swift; it resembles the sealy or green lizard, but is much slenderer and less; hind-legs marked with round patches.

CRUENTA; Red-tailed lizard. Tail verticillate, above cinereous, beneath scarlet with a whitish tip; fold of the neck beneath transverse. This species is found about the salt lakes in southern Siberia; resembles the velox in shape, but is three times as small, and has a sharper head. The body is brown, with seven white streaks on the neck, of which four reach the tail, beneath is white; limbs varied with round milky spots; thighs without the line of callous dots.

ARGUTA; the argute lizard. The specific character is this; tail short, verticillated; thick at the base and filiform at the tip; collar marked with obscure scales. There is a remarkable double plate under the neck.

The species is similar in some respects to the green lizard, but is shorter and more ventricose, and has a sharper snout. It is a native of the south of Siberia, and is found in the dry sunny places of Irtysh, and on the sandy plains beyond.

ALGERA. Tail long and verticillated, and two yellow lines on each side the body; it is a small species, of about a finger's length; it is brown above, and beneath yellowish; back covered with carinated scales, and bounded on each side by a yellow line, separating the abdomen from the upper parts. It is a native of Algiers.

TILIGUGU; Sardinian lizard. Tail round, conic, middle-sized; toes five, marginate claws.

It inhabits Sardinia, and is eight inches long. The body is thick, brown above, variegated with numerous black dots, beneath whitish; legs very short, the hinder ones longer; tail three inches and a half long.

URALENSIS; Ural lizard. Tail round, longish; neck beneath folding; feet all toed; back livid-ash, wrinkled, and subwarted.

It inhabits the country about Ural, is four inches long; very swift. The head is roundish; body whitish beneath.

BULLARIS; Bladder lizard. Tail round, long; chin pouched.

This species is about six inches long, of a shining grass-green colour. When it is approached, the throat swells into a globular form, and the protruded skin becomes of a bright colour. This has been thought to be a threatening aspect, but probably without any foundation. It is a native of Jamaica, where it is common about hedges and trees. The green Carolina lizard is supposed to be a variety of this species, as it is an exact resemblance in every respect, except in the appearance of the pouch. In dry hot weather it appears of a bright green colour; but in cold weather it changes to a brown. It is very common in and about the houses of Carolina.

AURITA; Eared lizard. Tail round, middle-sized, with callous dots on each side; the throat fold transverse, almost double; angles of the mouth each side dilated into a semi-

orbicular, soft, rough, dentate crest. This species is found among the sandy hillocks of southern Siberia, and gravel-pits in the desert of Comani, it is something larger than the gecko; the upper part waved with cinereous and yellowish, and thickly speckled with brown; underneath it is whitish; tip of the tail and blotch on the chest black.

TEGUINX. Tail round, long; lateral suture folded; neck beneath with a triple fold. Inhabits India and South America. Back and tail verticillate with crowded streaks.

HELIOSCOPIA; Star-gazing lizard. Tail imbricate, tapering; neck with a transverse fold beneath; head covered with callosities. This species inhabits in vast numbers the burning sand-hillocks of southern Siberia; moves very quick, but in a less serpentine direction than the scaly lizard; holds its head very erect with its eyes turned upwards, and is about two inches long. The colour of the upper parts of the body is grey, with brown and blueish spots, and linear streaks. The neck is often marked above with a red spot. The tip of the tail is red beneath.

PLICA; Plica lizard. The hinder part of the head is callous; eye-brows excoriated above; neck plaited beneath, and warted at the sides; tail long and round. This is a small species, about two or three inches in length. It is entirely covered with conical scales; there is a double plate beneath the throat. It is a native of South America and India.

Section I. Body lineate or banded, scaly; tongue bifid.

Species.

SEXLINEATA; Six-lined lizard. Tail verticillate, long; back with six white lines. It inhabits Carolina. The back is hoary, with three narrow white lines and three black; under the neck are two wrinkles; thighs with a row of callous dots behind.

QUINQUELINEATA; Five-lined lizard. This also is an inhabitant of Carolina. The head is marked with six yellow lines, and two between the eyes; back is blackish, with lines reaching to the middle of the tail; the tail half as long again as the body; the belly is streaked imbricately.

NILOTICA; or the lizard of the Nile. Tail long, the outer side triangular; body smooth; back with four lines of scales. It is found in Egypt.

INTERPUNCTATA; Asiatic lizard. Tail round, long; back with yellow lines, interspersed with black dots. Inhabits different parts of Asia. Body included between two lines and distinct from the sides. In the area are six longitudinal rows of brown dots, and as many on each side; legs and tail dotted in the same manner.

LEMNISCATA; Eight-lined lizard. Tail round, long; back with eight whitish lines. It inhabits Guinea. The thighs are dotted with white.

FASCIATA; Blue-tailed lizard. Tail round, long, blue; back with five yellowish lines. Inhabits Carolina.

VULGARIS; Brown lizard, or common Newt. Tail round, middle-sized; feet clawed; fore-feet four-toed; back with a double brown line.

It inhabits Europe, and is about three inches long. It is found in gardens, in the neighbourhood of dunghills, &c. Like the slug and toad it makes its way into cellars. It is altogether a land species, and it seems to be viviparous.

JAPONICA; Japanese lizard. Tail round, long; feet clawed; fore-feet four-toed; back banded. Body beneath yellow; the upper part is livid, with a dentate broad yellow band from the hind-head to the tip of the tail; eyes small; eye-brows large, rough; claws black; tail a little compressed at the tip. It is found in the Japan islands.

DESERTI; Ural lizard. Tail round, longish; feet five-toed; body above black, with six white longitudinal lines. It is found in the desert of Ural, and is somewhat more than two inches long. The body beneath is white; lines of the back consisting of oblong spots, and between each outer line, and the next, are five white dots.

QUADRILINEATA; Four-lined lizard. Tail round, long; feet somewhat clawed; hind-feet four-toed; body with four yellow lines. It inhabits North America.

PUNCTATA; Dotted lizard. Tail round, middle-sized; feet unarmed; fore-feet four-toed; back longitudinally dotted with white. It is found in Carolina. The body is brown, with a double row of white spots on the back, and a single one on the tail.

SPUTATOR; Spitting lizard. Tail round, middle-sized, with a longitudinal row of scales beneath; feet unarmed, five-toed; body cinereous, with white bands above, before and behind it is edged with liver colour. It is found in South America, in houses and among old buildings; when irritated, it discharges a black acrid matter, the effects of which on the human body may be cured by camphor or spirits of wine. The whole animal, except the very tips of the jaws, and the lower surface of the tail, is covered with minute truncate scales; the tongue is round, a little notched at the tip; tail near the end, and legs spotted with brown.

Section K. The belly of the animals of this division is covered with imbricate scales; the tongue is entire.

Species.

SEPIFORMIS. Tail short; body greenish-black; head armed; back flat; hind-thighs on the hinder part covered with callous dots.

SCINCUS; Scink. Tail round, middle-sized, compressed at the tip; toes unarmed, marginate. This species is thus characterized by Dr. Shaw. "Yellowish-brown lizard, with transverse brown bands on the upper part, short tail with compressed tip, and upper jaw longer than the lower."

"The scink," says the writer just quoted, "is one of the middle-sized or smaller lizards, and is a native of many of the eastern parts of the world. It abounds in Lybia, Syria, Egypt, and Arabia, frequenting moderately dry and sandy soils, and growing to the length of six or seven inches, or even sometimes more. The head of the scink is large, the body thick and round, and the tail considerably shorter than the body."

It is of a pale yellowish-brown colour, with a few broad, dusky, transverse undulations or zones, and is uniformly covered with moderately large or fish-like scales, lying extremely close and smooth, so that the surface has a glossy or oily appearance. It is an animal of harmless manners, and like most lizards derives its subsistence from various insects, which wander about the regions that it inhabits. It was once in high estimation as an article in the *Materia Medica*.

Mr. Bruce, in his *Travels*, has described the scink under the name of *El Adda*, which, he says, is very common in the province of Atbara in Abyssinia. (See *El Adda*.) It burrows in the sand so quickly, that it is out of sight instantly, and appears rather to have found a hole than made one, yet it comes out in the heat of the day to bask in the sun; and if not very much frightened, will take refuge behind stones, or in the withered, ragged roots of the abutthium, dried in the sun to nearly its own colour. It has long legs, but makes no use of them to stand upright; it creeps with its belly almost close to the ground; its motions are, however, very rapid. Mr. Bruce informs us, that lizards in general

are peculiarly numerous in the eastern regions. The desert parts of Syria bordering on Arabia Deserta abound with them to such a degree, as to render it impossible to count them. "I am positive," says the traveller, "that I can say, without exaggeration, that the number I saw one day in the great court of the temple of the sun at Balbec, amounted to many thousands; the ground, the walls, and floors of the ruined buildings were covered with them, and the various colours of which they consisted made a very extraordinary appearance, glittering under the sun, in which they lay sleeping and basking."

SCINCODRIS; Scincoid lizard. Tail round, middle-sized; legs short; toes very short.

This species is a variety of the *ocellula* of Dr. Shaw, to which he gives the name of the gallwasp. It is nearly two feet long, according to him; but Gmelin makes it about eighteen inches only. It is a native of New Holland. The body is a pale yellowish-brown, with a long patch of deep brown or blackish each side the neck; sides tinged with the same colour; tail deeper than the sides; teeth somewhat obtuse, short. The tongue in this, as in other scinks, is short, flat, rounded and entire; not forked, as in most lizards.

The *ocellula* or gallwasp itself is a native of the American islands, and is particularly common in Jamaica, where it frequents woody and marshy districts. Its colour is usually a palish brown, clouded with somewhat irregular bands of a deeper cast; but it is said occasionally to change its colour into a lively golden yellow. It was formerly thought to be the most venomous reptile in the island of Jamaica, and it was said that no creature could recover from its bite; but this is now regarded as a popular error.

OCELLATA; Ocellate lizard. Tail roundish, short; body beneath white, above greenish-grey, with roundish ocellate spots, brown on the margin, rectangular and white on the disk. It is found in Egypt, is very beautiful, and about a span long.

GUTTATA; Spotted scink. Tail round, long, the tip and four transverse spots black; body above hoary, dotted with white, beneath whitish.

It is a very small species, not much exceeding three inches in length. It inhabits the deserts of Ural. The body is smooth above; the feet are five-toed, with claws.

Section L. The animals of this division crawl on the belly; resembling both the lizard and serpent.

Species.

CHALCIDES. Tail round, long; feet five-toed; legs very short. Inhabits southern Europe and Africa. It is found of different sizes, from the length of a few inches to that of a foot, or even more. The head is covered in front with large scales, and is terminated by a slightly tapering, but not pointed, snout; the eyes are small, and the openings of the ears very distinct. There is no neck, the diameter continuing nearly equal from the head to the beginning of the tail, which is often longer than the body, and gradually tapers to a small point. The colour of this animal is pale ferruginous, or chestnut brown; hence its name, with some variations, is the "Ferruginous lizard."

In the living animal, the colour is generally said to have a kind of metallic or brassy cast, which probably gave rise to the specific appellation "*Chalcides*," and "*Chalcidica*."

"This singular lizard," says Dr. Shaw, "is described by Linnæus as having feet furnished with five toes; but whatever may have been the case with the individual specimen which he examined, it seems pretty certain that the general number is three. In the British Museum is an ele-

gant specimen. The *chalcides* is an animal of a very harmless nature, frequenting moist shady places, moving rather slowly, and feeding on insects, small worms, &c. It is a viviparous species, and is said to produce a great many young. The serpents to which it bears the nearest alliance, in point of form, are those of the genus *anguis*, and particularly the *A. fragilis*, or common slow-worm."

The "*Chalcide*," described by the count de Cope, appears to be extremely allied to the one just mentioned; but, instead of having imbricated scales, it is marked into a continual series of annuli throughout its whole length.

SERPENS; Serpent lizard. Head, body, and tail, a continued cylinder; legs very minute, remote, five-toed, and clawed. It inhabits Java; is about four or five inches long. Its shape is very much like that of a serpent, but more conical; the upper part of the body is decorated with from fourteen to twenty brown, longitudinal stripes; beneath it is silvery. It has an auditory canal.

ANGUINA; Snake lizard. Tail verticillate, flimsy at the extremity; body striate; feet without toes, subulate. The animals of this species are about fourteen inches long, of which the body itself is only four. The head is rather small; the snout taper; the legs very short, placed near the head and vent, and apparently terminating in one undivided toe or process; the whole animal appears covered with ovate scales, and is brown above, ash-coloured on the sides, and yellowish beneath; the upper surface is marked throughout its whole length by several dark lines or stripes. It is a native of the Cape of Good Hope, where it is found in great plenty in the water, and about the rocks in the Table bay.

LUMBRICOIDES; Lumbriciform lizard. Body subequal, round, ferruginous, tessellate with square streaks; beneath paler; there are no hind-feet, but the others are short and four-toed. This is the *la canelle* of the count de Cope, who first described it in his History of Oviparous Quadrupeds. Its length is about eight inches, of which the tail is only one inch. Along the whole body, from head to tail on each side, runs a continued sulcus or channel, separating the upper and lower surfaces; legs only two, extremely short, placed near the head, and divided into five minute toes with claws. Colour of the living animal suspected to be green; paler beneath. It inhabits Mexico.

BIPES; Biped lizard. Body subequal, round, pale, imbricate; each scale with a brown dot. There are no fore-feet; hind-feet with two toes. This is a very small species, said to be found in South America and in India. Its length is six inches; the diameter no larger than that of a good sized goose-quill. This lizard was described by Linnæus in the Museum Adolpho Frederici, as a species of snake, under the title of "*Anguis bipes*."

APUS; Cylindrical lizard. Head, body, and tail, a continued imbricate cylinder; it has no fore-feet, and scarcely any that can be so called behind. This species is a still nearer approach to the snake tribe than even the *chalcides*. It is a native of Greece, the southern parts of Siberia, and probably of many other parts of Europe and Asia. It is sometimes full three feet long, and so perfectly resembles the general form of a large snake, that it requires very close inspection to find that it belongs to the race of lizards. It inhabits the grassy meadows of the deserts of southern Siberia, and near the rivers Sarpa, Coana, and Terok. Though in general appearance it resembles a snake, in its internal structure it is formed like a lizard.

Two specimens of this lizard were brought from Greece by Dr. John Sibthorp, professor of botany in the university of Oxford.

Having,

Having, in the foregoing account, followed the Linnæan system, with such occasional additions and illustrations as occurred from other writers of distinguished reputation; we shall conclude with noticing some species which later naturalists have added to this genus, and which have been described, and most of them figured, in the interesting works of Dr. Shaw. Of these the first is the

ACANTHURA. The specific character of this is as follows: Throat plaited beneath; the body covered with minute scales; the tail long, and verticillated with carinated triple-spined scales. A specimen of this animal is preserved in the British Museum. Its length is a foot and a half; the head resembles that of the ameiva and teguixin, is covered with rather small subhexagonal scales, and is very distinctly marked off, as it were, from the body; beneath the throat is a conspicuous transverse plait; the whole skin about the neck, throat, and beginning of the sides, is very lax, so that it is thought in the living animal the skin beneath the throat may have a kind of pouch appearance, though entirely without any middle carina on that part: the feet are all pentadactylous, and the toes rather long. The colour of this species on the upper part is glaucous, variegated with a few small and somewhat indistinct clouds and marblings of a whitish cast; the tail and under parts are of a pale or yellowish-white colour. Dr. Shaw says, this species is much allied to the quetzaleo of Seba, which is generally supposed to represent the azurea of Linnæus.

LOPHURA. Body covered by dissimilar scales; the back serrated; the tail is long and carinated. This is a very large species, resembling the teguixin in size, colour, and some other respects, but is coated with scales of dissimilar size on different parts. Specimens are found in the British Museum, and in that of Dr. William Hunter.

ERYTHROCEPHALA. Blackish-green, with transverse black undulations; abdomen longitudinally banded with black, white, and blue; the breast black, and the top of the head red. This, which is reckoned a middle-sized species, is a native of the island of St. Christopher, and is described by the count de Cépède. Colour deep or dark green above, mixed with brown; back marked by several transverse black undulations; top of the head and part of the sides of the neck red; throat white; breast black; belly variegated with longitudinal black, blue, and whitish bands, and covered with scales or plates. The head is covered with larger scales than the other parts; beneath the thighs is a row of tubercles.

TENIOLATA. Lizard with long round tail, and body marked above with black and white stripes; beneath it is white. This species, allied to the fasciata, is covered entirely with scales; colour chestnut brown above; pale or whitish beneath; on the back six narrow white linear stripes, the intermediate spaces of the central and lowermost stripes being black; the tail is long and narrow; limbs striped longitudinally with black. It is slender, five-toed, and a native of New Holland.

SINENSIS. Tail flat, all the toes unguiculated, and the face perforated by several pores. This species, which is omitted in the Syst. Nat., was first described by Osbeck, who observed it in China, where it is frequently seen in houses, running about the walls, and climbing with extreme readiness on the smoothest surfaces, preying chiefly on the smaller kind of blattæ.

FIMBRIATA. Body with a membranaceous fimbriated border on each side of the body, tail flat, and lamellæ of the feet divided by a furrow. This species was first described by the count de Cépède, who informs us that it appears in some degree to connect the chamæleon, the gecko, and the

water-newts: the head, skin, and general form of the body, resembling those of the chamæleon; the tail, that of the water newts; while the feet resemble those of the gecko.

The colour of this animal is not constant or permanent, as in most of the lizard tribe; but variable, as in the chamæleon, presenting successively shades of red, yellow, green, and blue. This variation of colour is confined to the upper surface of the animal; the lower always continuing of a bright yellow. These several changes have been observed in the living animal in its native country, Madagafcar, where it is rather common, and where, though harmless, it is held in great abhorrence by the natives, who believe that it darts on their breast, and adheres with such force by its fringed membrane, that it cannot be separated from the skin without being cut off. Its residence is on the branches of trees, where it lives on insects, holding itself secure by coiling its tail half round the twig on which it sits. It chiefly appears in rainy weather, when it moves with great agility, often springing from bough to bough.

LIZARD, Devil. See MAEOUJAS.

LIZARD, Fly-catching. See GOEMOUC.

LIZARD Island, in Geography, one of the islands called "Direction islands," in the South Pacific ocean, about 240 miles in circumference, and in general rocky and barren. Captain Cook gave it the name on account of the number of lizards, some of which were very large, which he found upon it; 20 miles N.E. of Cape Flattery.—Also, one of the smaller Bahama islands.

LIZARD Point, or The Lizard, a promontory on the south coast of Cornwall, and the most southern point of land in England, at the north entrance of the English channel. N. lat. 49 59'. W. long. 5° 12'.

LIZARD, in Naval Rigging, an iron thimble spliced into the main bow-lines, and pointed over to hook a tackle to.

LIZARD'S Tail, in Botany. See SAURURUS.

LIZENED CORN, in Agriculture, a term provincially used for shrunk or lank corn.

LIZIERE, the same with *berme, forland, or relais*.

When this space is covered with a parapet, it is called a *fausse-braye*, or low wall.

LIZOU-TCHEOU, in Geography, a city of China, of the first class, in the province of Quang-si, on the river Long. N. lat. 24 12'. E. long. 108 47'.

LIZY-SUR-OURCQ, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Meaux. The place contains 1200, and the canton 11,885 inhabitants, on a territory of 245 kilometres, in 28 communes.

LLALA, a town of Peru, in the audience of Lima; 100 miles N. of Lima.

LLAMA, or GLAMA, in Zoology. See CAMELUS.

LLANBADARN VAWR, in Geography, a market town and parish in the hundred of Genecin Glyn, Cardiganhire, Wales. This place is supposed to have been anciently called *Mauritania*, and to have changed its name in the sixth century, in memory of St. Paternus, who built a monastery here, which was afterwards constituted an episcopal see. This dignity it retained till the inhabitants, quarrelling with the bishop, murdered him, when it was united to the see of St. David's. The government of the town is vested in a portreeve. It has a small harbour; but the little trade it formerly possessed has of late years been transferred to Aberystwith. The market for meat is now likewise held at the same place, so that this town is much declined. The ancient church, built in the form of a cross, and surmounted by a massive square tower, is a large edifice, in an early style of architecture. It is remarkable as the seat of one

of the oldest bishoprics in Wales. The interior contains a few modern monuments, one of which was raised to the memory of Lewis Morris, the celebrated author of the "Celtic Remains." In the church-yard is an ancient cross, finely decorated with fret-work. The parish is very extensive, and contains a number of hamlets, of which Aberystwith is the largest and most populous. The waste lands, or commons, may be about 8000 acres. Several old British forts and tumuli can easily be traced in different parts of it. In a vale, called Dyfryn castell, is a circle of stones, which tradition informs us was a Druidical temple and court of judicature. This town and parish were entirely laid waste by the Danes in the year 988. The town was soon rebuilt; but in little more than thirty years after again suffered a similar fate, being burnt to the ground by Gruffydd al Llywellyn, during his contest for the sovereignty of this district with Howel ap Edwin. The houses in this parish, according to the parliamentary returns of 1800, amounted to 240 in number, and the inhabitants to 1228. For an ample and interesting account of this parish and the county, the reader is referred to a volume recently published by S. R. Meyrick, entitled "The History and Antiquities of the County of Cardigan," 4to. 1808.

LLANBEDER, *Llanbeder*, or *Llanbedrport-Stephen*, a market-town and parish in the hundred of Modwyn, and county of Cardigan, South Wales. It is a corporation, governed by a portreeve, bailiff, and town-clerk, and joins with Cardigan, Aberystwith, and Aspar, in returning one member to parliament. The addition of Pont-Stephen to the name of this place is supposed to have arisen from the circumstance of king Stephen having thrown a bridge over one of the principal trenches of a camp in this vicinity. The market is held here on Tuesday. The principal traffic consists in horses, cattle, and hogs, vast numbers being bought for the English markets. The foundations of a noble castle, which anciently stood in this neighbourhood, can still be discovered at a very short distance from the town. The old family mansion of the Llo-ys forms a very curious and picturesque object. It is surmounted by four lofty turrets, which, peeping through a thick planted inclosure, have a striking appearance. The parish is small, and the soil remarkably unproductive, though much improved of late years, by the free use of lime. The houses, according to the parliamentary returns of 1800, amount to 161 in number. The inhabitants were estimated at 669. Meyrick's History, &c. of Cardiganshire, 4to. 1808.

LLANDAFF, *i. e.* the church upon the Taff, a city in the hundred of Kibbor, and county of Glamorgan, South Wales. It is watered by the river Taff, which falls into the Severn, about four miles below the town. The name of this place is supposed to be a corruption of the word *Llanar-daff*, signifying the church on the Taff, the walls of the cathedral burying-ground being close upon its banks. Llandaff, though a very ancient city in appearance, is only a straggling village, placed on an easy eminence. The parish includes the hamlets of Canton, Ely, Fair-er, Gabalfa, and Llandaff. The parish comprehends 2399 acres of land. It has no market; but has the advantage of a tolerably good harbour, which opens into the Bristol channel. This place is now chiefly supported by Cardiff, which is two miles W N W. It deserves notice principally on account of its cathedral-church, which is said to have been first founded here soon after the introduction of Christianity into Britain. *i. e.* A. D. 186. It was not, however, till the beginning of the sixth century, that Llandaff was raised to the dignity of a bishop's see, by Myric, king of the Silures, who endowed it with all the lands between the rivers Taff

and Elwy. The original church being destroyed at the time of the conquest, or at least its oldest part, the present was erected in the year 1120, by bishop Urban. Its situation is truly monastic, in a bottom surrounded by rising ground. According to Grose, it measures in length, from east to west, 203½ feet. The breadth of the body is 65 feet, and the height from the floor to the centre of the roof 119 feet. The west front is a beautiful relic of the Norman and pointed styles of architecture united. At the corners of this front formerly rose two magnificent towers, one of which is now nearly destroyed. That on the north-west, still remaining entire, is embellished with a profusion of sculpture. The entrance on this side is under a semi-circular arch, over which are three windows, with lancet-shaped arches. The interior contains several monuments of the bishops; also, one in honour of the lady Godiva, the celebrated patroness of the men of Coventry. A full description of this church, with views and details, will be found in N° 1. of Cooper's Architectural Reliques. Nothing can exceed the absurd and fantastical appearance of this edifice, when viewed as a whole. Beneath the towers has been ingrafted an Italian summer-house, with a Venetian window, also pilasters and flower-pot jars upon the parapet. The ecclesiastical establishment of this see consists of a bishop, as dean, an arch-deacon, a sub-dean, a chancellor, precentor, and nine prebendaries. The choral-service has long been discontinued; and the cathedral used as the parish church. A chapter-house, in the kitchen, and an office for the proctor general, have been erected in the church-yard, where the officers meet once a-year at Peter's-tide, for the auditing of accounts, &c. Two vicars are appointed by the chapter to serve Llandaff and Whitechurch alternately. The petty sessions for the hundred of Kibbor are holden at Llandaff. The bishop has no palace here, nor are there any established houses for other members of the church. The diocese contains about three-fourths of the county of Glamorgan, and all Monmouthshire, but seven parishes. A gate-way and a ruined tower, which formerly contained the great bell called Peter, now at Exeter, are the only remains of the bishop's palace. The names of the prelates of this see have been preserved by historians from the period of its erection, though with much uncertainty as to the dates of their consecrations and deaths, till the close of the ninth century. Llandaff, according to the parliamentary returns of 1801, contains 191 houses, and 860 inhabitants. Two fairs are held here annually, one on the 9th of February, and another on Whit-Sunday. Brown Willis has published an history and description of Llandaff cathedral in 1 vol. 8vo. See Malkin's Account of South Wales, 2 vols. 8vo. and Donovan's Tour through South Wales, &c. 2 vols. 8vo. Hoare's Edition of Giraldus Cambrensis, 2 vols. 4to. 1809.

LLANDEILO VAWR, a market-town and parish in the hundred of Penfedd, and county of Caermarthen, South Wales. The town is situated on the declivity of a hill, at the bottom of which flows the river Towy, or Tywi, giving name to one of the most delightful vales in the county. The town itself has very little to recommend it, the streets being extremely narrow, steep, and irregular. The church is an ancient low building, and consists of two aisles. The pillars which support the roof do not exceed five feet in height. A market, held here every Saturday, is well supplied with provisions. Llandeilo is 15 miles E. by N. from Caermarthen, and 202 W. by N. from London. No less than eight fairs are held annually in this town, and another at Fair-Pach, about one mile distant. The parish comprehends an area of about 16 miles from north to south, by eight miles

miles from east to west. About one-tenth part of this land is uncultivated. On an eminence about one mile distant from the town, to the S.W. stands the picturesque ruins of Dinevor, or Dinas-fawr castle, which commands some of the finest and most romantic views of the scenery of Newtonpark, and the extensive vale of Tywi. This castle was built by Rhys ap Theodore, in the reign of William the Conqueror. It seems to have been originally of a circular form, and strongly fortified by a double moat and rampart. This castle was for some time the royal residence of the princes of South Wales. South from it are the ruins of Cappel yr Ywn, standing between two round towers. It was formerly a chapel of ease to the mother-church. At some distance to the westward is Grongar-hill, which has been immortalized by the muse of Dyer. At a short distance, on a rugged hill, stand the mouldering fragments of Drulwyn-castell. About four miles S.E. of the town are the picturesque ruins of Craig-Cenen-castell, *i. e.* the castle on the rock by the Cenen. The situation is singularly romantic, being seated on an insulated rock, which was inaccessible on all sides but one. It is supposed to have been erected by Geronw, lord of Is-Cenen, who was one of the knights of king Arthur's round table. The well in this castle is considered a singular curiosity. The farm-house, called Cwrt Bryn y Beiridd, which lies about a mile to the south of this castle, was formerly a celebrated bardish residence. Here the river Llychwr takes its rise, issuing with a copious stream immediately from the solid rock. Close to this spring is a cavern, in some places so narrow, as hardly to permit a person to pass through, but in other parts extremely spacious, and exhibiting a variety of beautiful petrifications. At Llan-de-Faen, which lies to the south-west, at the distance of four miles, is a well formerly considered as very efficacious in paralytic and scorbutic affections. Besides this, there are other chalybeate springs in different parts of the parish; but none possess any peculiar medicinal properties. Near Llandeilo-vawr are Talieris-park, the seat of lord Robert Seymour; and Edwinstford, the seat of J. H. Williams, esq. The river Tywi, which, passing the town, meanders along the vale, abounds with excellent salmon-trout and eel. According to the history of Wales, by Carradoc of Llan-carnvan, the last decisive battle between the forces of Edward I. and Llewellyn, prince of Wales, was fought in this neighbourhood. The victory remained with the English, and put a final period to the independence of Wales. The inhabitants of Llandeilo, according to the parliamentary returns for 1801, are estimated at 647, and the houses at 141. Wyndham, Skrine, Malkin, Barber, and Sir Richard Hoare, in Giraldus Cambrensis, have given accounts of this town and its neighbourhood in their respective Tours.

LLANDOVERY, or LLAN-YM-DYFFUL, a market-town and parish of Llan-Dinod, and hundred of Penfedd, Caermarthenshire, South Wales. The town is situated on the river Brane, near its junction with the Towey, and consists of five streets, containing, according to Mr. Carlisle, about 800 inhabitants. The buildings of this town have a low and mean appearance. On a mound near the centre of the town, and surrounded by a deep trench, are the ruins of a small castle, built by Richard de Powers, and it is remarkable for the birth and residence of the celebrated Rees Pritchard, (Rhys Prytherch, well known throughout Wales as author of the "Vicar's Book," a collection of very simple poetry. This castle was besieged in 1116 by Gruffydd ap Rhys, who burnt the outer ward, and put a great part of the garrison to the sword; but his own troops, in effecting this object, sustained so considerable a loss, that he was compelled to raise the siege. The site of this castle is very remarkable, being an insulated rock of some elevation, totally uncon-

nected with any adjacent rising ground. A handsome stone bridge is here thrown across the river Brane. The church stands on an eminence at one end of the town. It does not possess any thing worthy of being particularly noticed. The market is held on Friday every week, and, considering the extent of the place, is one of the largest and best supplied in Wales.

Llandovery is undoubtedly a town of considerable antiquity: it rose upon the ruins of a Roman station, which was at or near Llan-Fair-ar-y-Brynn, about half a mile distant. That these celebrated conquerors had a fixed residence there, is sufficiently clear from the number of Roman bricks, earthen pots, coins, and other remains of antiquity, which have been discovered on that spot. This town was formerly a contributory borough to Caermarthen, but the privilege has been lost for a considerable period. It still, however, retains its charter, by virtue of which a bailiff is annually elected, as are likewise a recorder, a town-clerk, aldermen, and sergeants at mace; but their offices at present seem to be little more than nominal. The county magistrates hold here the petty sessions for the upper division of the hundred of Penfedd. It possesses no less than five benefit societies, three for men and two for women, which are said to be extremely advantageous to the subscribers.

The neighbourhood of Llandovery is distinguished by a most enchanting display of the more placid description of mountain scenery. The pass of Cwm-Dwr, which winds round the Black mountain to the east, is peculiarly fine. On a part of this mountain the decayed town of Trecate is situated; but it contains nothing worthy of attention, except the remains of a castle erected by Bernard de Newmarch, in the reign of William Rufus. On the summit of the Gaer hill is a Roman encampment, part of the fortifications of which are still tolerably entire; and on Pen y Craig an oval one, with three fosses and two vallums, supposed to be of British construction. A monumental stone, about six feet high, called Maen y Morynnion, is placed on an old Roman causeway which joins the road to Brecknock. It seems to have been richly sculptured. The words "Conjux ejus" are the only ones of the inscription that can now be distinguished. Carlisle's Typographical Dictionary of Wales, 4to. 1811. Skrine, Malkin, and Evans's Tours in South Wales.

LLANDRINDOD, or TRINITY-CHURCH, a village of South Wales, in Radnorshire, near which are medicinal springs, much frequented; 8 miles W. of New Radnor.

LLAN-ELLY, a market-town and parish in the hundred of Carnwylion, in Caermarthenshire, South Wales, contains, according to the parliamentary returns in 1801, 501 houses, and 2972 inhabitants. The market-days are Thursday and Saturday. The buildings of the town are irregularly situated upon a creek near the sea-shore. At the mouth of this creek is a small island, formed by the river Bury, where a monastery, founded by St. Piro, formerly stood. The church, dedicated to St. Elli, is an old structure, remarkable for its high, square, embattled tower. The inhabitants of this place are chiefly miners and sailors. The coal wrought in the vicinity is reckoned remarkably fine. The harbour is tolerably large, and is the controuling port both for Caernarvon and Kidwelly. Two fairs are held here annually: one on Ascension day, and the other on the 30th of September. The parish contains about 15,000 acres of land, of which nearly 3000 lie uncultivated and without cultivation. The hamlets are Berwich, Glynn, Hên Coed, Westflowe, and the Borough hamlet. At Berwich and at Ddewi the ruins of two chapels can still be distinguished. The chapel of St. John has been lately repaired by

by inscription, and is at present used as a meeting-house by the Methodists. Pembree-hill, a few miles distant from the town, commands one of the finest and most extensive marine views to be found in any part of Great Britain.

LLANES, a small sea-port town of Spain, in Asturias, near the North coast; 54 miles N.E. of Oviedo.

LLAN-GADOG VAWR, a market-town and parish in the hundred of Penfedd, and county of Caermarthen, South Wales. The town, which stands between the rivers Brane and Sawdde, is tolerably well built, but was formerly much more extensive than at present. It lies about 6 miles S.S.W. of Llandovery, and 100 W. by N. from London. A small manufacture of coarse woollens and stockings is carried on here, principally to supply the consumption of the town. The market-day is Thursday; and the fairs are held on the 12th of March, the last Thursday of May, 9th of July, the first Thursday after the 11th of September, and the second Thursday after the 11th of December. The ancient castle, mentioned by many tourists, has been for many years entirely demolished. A collegiate church is said to have been founded here, A.D. 1283, by Thomas Beck, bishop of St. David's, in honour of St. Maurice and his companion, and St. Thomas the Martyr. This distinction seems to have been enjoyed but a very short time, if it ever actually took place. The present church is dedicated to St. Cadog, and the living is a vicarage in the gift of the bishop mentioned above. Bledri, the son of Cedifor, the great lord of Gwydigada and Elfed, who died in 1116, was buried here. The parish contains three hamlets; the hamlet of Dyffryn Caead/Rhyfch, the hamlet of Gwynfe, and the hamlet above the Sawdde. The population, according to the parliamentary report of 1801, amounted to 1821 persons.

LLANGOLLEN, a market-town and parish, situated in the hundred of Chirk, and county of Denbigh, North Wales. The houses of the town have a mean appearance. According to the parliamentary returns for 1801 they amounted to 281, and the inhabitants to 1287. The church is nowise remarkable, excepting for the length of the name of its patron saint, *i. e.* St. Collen ap Gwynnawg ap Clydawg ap Cowdra ap Caradog Fruelifras ap Lley Merim ap Eynion Yrth ap Cunedda Wledig. The market is held here on Saturday every week, and there are four fairs annually. The ruins of Castell Dinas Brân nearly cover the summit of a vast conoid hill, which begins its ascent near the foot of the bridge opposite to the town. This is one of the primitive Welsh castles, but the name of its founder is unknown. The form of it is oblong, extending about 300 yards in breadth, and 150 in length. On one side of the hill, which is less steep than the others, deep trenches are cut through the solid rock. The materials composing this building are the common coarse stone of the country, interspersed with a few free-stone mouldings. In the reign of Henry III. this castle served as an asylum to the traitor Gryllfydd ap Madog, who, basely taking part with the enemies of his country, was compelled to secure himself in this aerial fastness. It afterwards became the residence of Mufamvay Vechan, the beautiful and accomplished mistress of Hoel ap Eynion, one of the most illustrious of the Welsh bards. It is remarkable that this castle stands at least 600 yards above the level of the sea: the two springs within its walls are never deficient in water. On the north-side of the hill may be seen a vast rock, called Craig Eglwyseg, or the Eagle's Rock; the strata of which are so placed upon one another as to form a series of steps parallel with the horizon, known to naturalists by the name of *Saxa sedilia*. The bridge at the bottom of the hill is one of the most beautiful and romantic in Wales, and is ge-

nerally reckoned among the wonders of the principality. The foundation is on the ledge of a rock. It consists of four arches, the centre one of which is 30 feet in diameter. Tradition informs us it was the work of Trevis, bishop of St. Afaph, in the year 1400. About two miles from the bridge stands the abbey of de Valle Crucis, one of the finest specimens of architectural antiquity in Wales. The western window has been adorned with a variety of sculptural ornaments, but most of them are entirely defaced. Concerning the etymology of the name of this abbey historians are not agreed; some deriving it from the buildings being in the form of a cross, and others from the circumstance of its monks having made a present of a part of the true cross to Edward I. At the distance of a quarter of a mile hence, is the remainder of a round column, called the pillar of Eliseg, which is perhaps one of the most ancient British pillars now existing. It was entire till the time of the great rebellion, when it was thrown down and broken by some ignorant fanatics, on account of its resemblance, in figure, to a cross. This pillar has, no doubt, been erected to perpetuate the memory of some celebrated chief. It stood on a great tumulus, and, when complete, measured 12 feet in height. The inscription was copied by Mr. Edward Llwyd, but it is now entirely illegible. From the shape of the letters in the copy taken by that great antiquary, it is concluded to have been written some time in the sixth century. The tumulus was opened some years back, when some bones were discovered placed between flat stones.

The beauties of the vale of Llangollen are celebrated both in prose and verse. It is watered by the river Deva, and has a canal from the Pont y Cryfylltan aqueduct running throughout its whole length to the Oernant slate-quarries. The low price of labour, and the great plenty of provisions and fuel, have lately induced several adventurers in the cotton manufacture to establish some extensive works in this neighbourhood. The great mail-road from London to Holyhead passes through both the vale and town. The parish is very extensive, and is divided into three portions, called Traian y Glynn, Traian Llangollen, and Traian Trevor; each of which contains several hamlets. We might have mentioned the romantic residence of two ladies, who have for many years lived together in the vicinity of this town. It is well known by all tourists. Pennant, Skrine, Bingley, Wyndham, Evans, Warner, and Hutton have given accounts of Llangollen, and of the principal places in its vicinity, in their respective tours in Wales.

LLANNERCH Y MEDD, a market-town, situated chiefly in the parish of Amlech, in the hundred of Twr Celyn, and county of Anglesea, North Wales. A market is held here on Wednesdays, and the fairs on the 5th of February, 25th of April, 6th of May, and Thursday after Trinity. This town owes its support principally to the circumstance of its being stationed in the neighbourhood of the Parys mountain. The petty sessions are held here. Aikin's Tour in North Wales.

LLANOS, Los, a town of Mexico, in the province of Mechoacan; 100 miles N.N.E. of Mechoacan.

LLANOS De Almeria, a town of Spain, in the province of Grenada, on the coast of the Mediterranean; 20 miles W.S.W. of Almeria.

LLAN RHAIADAR, in Mochmant, a parish consisting of 17 townships, situated partly in the hundred of Chirk, and county of Denbigh, and partly in the hundred of Llan-Fyllin, in Montgomeryshire, North Wales. It lies in a deep hollow, surrounded by lofty mountains. The petty sessions for the division of Cynllaeth and Mochmant are held in the village which gives name to the parish. William Morgan, D. D. an eminent divine, and the person who

who first translated the bible into Welsh, was vicar here, till translated to the see of Llandaff, by queen Elizabeth in the year 1595. The buildings of the village are ancient and irregular. The rectory is a sinecure in the patronage of the bishop of St. Asaph. According to the parliamentary returns for 1801, the whole parish contained a population of 1869 persons.

LLANRWST, a market-town and parish, situated in the western extremity of the hundred of Uwch Dulas, and county of Denbigh, North Wales. The town is watered by the river Conway, over which, at this place, is a noble bridge of three arches, built by the celebrated Inigo Jones in the year 1636. The market is on Tuesdays, and there are four fairs during the year. Here are held the petty sessions for the hundred. Mr. Burke calls this "the most charming spot in Wales." In the town is a good market-hall, and a richly endowed free-school. A small trade is carried on in harp-making, and it is the centre of all the business of the populous vale in which it stands. The church is supposed to have been built in 570, and is dedicated to St. Grwft, who was a bishop of London about the year 360. In this church is some curious carved work, said to have been brought from the neighbouring abbey of Maenan. Adjoining to it stands a chapel, erected by Sir Richard Wynne, after a design by the architect already mentioned. Here are a few monuments in honour of the Wynne family, which deserve the attention of the curious. They are brasses, each containing, besides the inscription, a portraiture of the person to whose memory they were engraved. An ancient monument of Howel Coytmore has been lately removed from the church to this place. Near it is a large stone coffin, supposed to be that of prince Llewelyn ap Ierwerth, who was denominated Llewelyn the Great. The high road from Shropshire to Holyhead passes through the town. In the neighbourhood stands Gwydw-house, an ancient mansion, consisting of an extensive pile of buildings, of irregular appearance, but sufficient to denote the great opulence and splendour of its former possessors. Immediately behind the house the ground rises rapidly to the foot of the perpendicular cliffs which form the western boundary of the valley. All this space is now covered with fine plantations of different kinds of trees. Half way up the rock, on an irregular plain of nearly five acres in extent, are the remains of a terrace, and a handsome domestic chapel, in the pointed style of architecture. About a mile from the town, at the hamlet of Mayne, is a spring in high repute for its medicinal virtues. Five miles to the south-east lies the ancient nunnery of Gwythwin, where St. Winefrid is said to have been buried. The box which contained the relics of this saint is still pointed out to strangers, but her chapel on the south-side is totally demolished. The church-yard contains four upright stones, one of which is in the shape of a prism, and bears an inscription now illegible. North of Llanrwst, at the distance of three miles, the abbey of Maenan formerly stood. Its site is now occupied by a large old house, built out of the ruins. The resident population of this parish, according to the parliamentary returns of 1801, amounted to 2549 persons. See the *Tours of Pennant, Wyndham, Aikin, Bingley, Skrine, Warner, Evans, and Hutton*: all of whom visited this part of Wales.

LLANSTEPHAN, a village in the hundred of Derllys, and county of Caermarthen, South Wales, is seated beneath a hill, in a woody vale; whence the situation is peculiarly picturesque and interesting. Here is a well, called St. Anthony's, which formerly was in high estimation for its medicinal

virtues; but it has not been much resorted to of late years. Here was formerly a castle, which is now in ruins. It is situated on an eminence, on the western side of the entrance of the navigable river Tywi, or Towey. Its broken walls enclose a large area; and furnished with several encircling earthen ramparts, appear to have possessed considerable strength. This castle is said to have been built by the sons of Uchred, prince of Merionethshire, A. D. 1138. There is a handsome modern house on the hill on which the castle stands. The parish of Llanllefhan, which includes the hamlets of Aliston, Laques, and Llan y Bre, contained, according to the return to parliament in 1801, a population of 974 persons, inhabiting 205 houses. *Carlisle's Topographical Dictionary of Wales*, 4to. 1811.

LLANTRISSANT, a borough and market-town in the hundred of Miskin, and county of Glamorgan, South Wales, is situated near the summit of a cleft in one of the high hills which abound in the vale of Glamorgan. The only access to it is by a steep circuitous road. One narrow irregular street, composed of poor habitations, makes up nearly the whole of this place. The church is a large Norman structure. The cemetery affords a very extensive prospect. Here was an ancient Norman castle, of which but little now remains, except the fragment of a circular tower; the vestiges of the outworks being nearly concealed by shrubs. Within the precincts of the castle are the town-hall and market-house, new buildings erected by the late earl of Bute. The borough is governed by a portreeve, and unites with Cardiff, Swansea, &c. in sending one member to parliament. Llantrissant is distant from Llandaff 10 miles, and from London 170: a weekly market is held on Friday, and three fairs annually. In the year 1801, the parish was returned as containing 376 houses, inhabited by 1715 persons. *Barber's Tour in South Wales*, 8vo.

LLANVYLLING, a market-town in the hundred to which it gives name, in the county of Montgomery, North Wales, is situated in a pleasant valley, near the river Cane, 15 miles from Montgomery, and 186 from London. The town is neat, and many of the houses are well built. It was first incorporated by Llewellyn ap Gryffydd, lord of Mecham and Mochnant, in the reign of Edward I.; and is governed by two bailiffs, chosen annually, who are justices of the peace during the time of office. Many Roman coins have been found here. Four fairs are held annually, and a weekly market on Tuesday. According to the population report of the year 1801, Llanvylling contained 444 houses, and 1394 inhabitants. *Pennant's Tour in Wales*, and *Skrine's Tour*.

LLANAVRTYD WELLS, a medicinal spring of South Wales, in the county of Brecon; 12 miles W. of Builth.

LLANYDLOES, a market-town in the hundred of the same name, and county of Montgomery, North Wales, is pleasantly situated near the bank of the river Severn, 13 miles from Newtown, and 180 from London. Several of the streets are spacious, but the buildings are irregular, and chiefly of lath and plaster. The church is a neat edifice, being supported by six arches, the pillars of which have capitals of palm-leaves, and are said to have been brought from Cwmber Abbey. About the town are several very extensive sheep-walks; and a number of persons are constantly employed in the neighbouring slate quarries. The parish consists of the townships of Brithdir, Cil-Machen, Glynn-Hafren-Is-Coed, Manleodd, Merfodion, Treffin, and Yltrad Dunod. The petty sessions for the hundred are holden here. Llanvdyloes was formerly a contributory borough to Montgomery, but was disfranchised with Pool and Llan-

Yllin. The town however has still the nominal appendages of a mayor, and his subordinate officers. A considerable manufactory of flannels is carried on here. Pennant, Evans, Bingley, and Skrine describe this place in their neighbourhood in their respective tours in North Wales.

LIMATA, a town of Peru, in the diocese of Lima; 90 miles from Lima.

LILAUGHARNE, LLAUGHARN, Lalebarn, or Laugharne, a market-town, sea-port, and parish, in the hundred of Derlis, Caermarthenshire, Wales. The town is situated at the mouth of the river Coran, and is one of the most frequented towns in the principality. The church is a large handsome building, in very excellent condition. Towards the south end of the town, and close upon the bay of Caermarthen, stand the ruins of an old castle, which is said to have been erected, or at least re-built, by Guido de Brian, in the reign of Henry III. The remains of the gateway, which is covered with a profusion of ivy, and various other parts of it, are still in good preservation. The corporation of Llaugharne consists of a portreeve, a recorder, an indefinite number of aldermen, two common attorneys, four councillors, and 76 burgesses. The market is held on Fridays, and there are two fairs annually, but these are very inconsiderable. This was the birth-place of a celebrated political writer and divine, Dr Josiah Tucker, who died in 1799.

At a short distance from the town are the vestiges of a ruin, now called Roches castle. This building, according to tradition, was formerly a monastery, but when it was built, or by what order of monks, is wholly unknown. The parish church is said anciently to have stood on the farm named Crafeland, i. e. Christ's land, but no traces of such a building can now be discovered. In the year 1801, this town contained 1484 inhabitants.

LLECH, the Welsh name for a kind of monumental stone found in that country. See **PILLAR**.

LLENDILAFAYA, a town of Spain, in the province of Asturia; 8 miles S.W. of Oviedo.

LLERENA, a town of Spain, in the province of Estramadura, belonging to the knights of the order of St. Jago, by whom it was founded; 53 miles E. of Cordova. N. lat. 38 7'. W. long. 5 59'.—Also, a town of Mexico, in the province of Zacatecas; 80 miles N.N.W. of Zacatecas. N. lat. 23 48'. W. long. 104 46'.

LLIRIA. See **LIRIA**.

LLIVIA, a town of Spain, in Catalonia, in the Pyrenees, near the source of the Segre, anciently called "Julia Libyca;" 6 miles N.E. of Puycerda.

LLOBREGAT, a river of Spain, in Catalonia, which runs into the Mediterranean, about 9 miles W. from Barcelona.

LOMSA, a town of the duchy of Warlaw, on the Narew; 70 miles N.N.E. of Warlaw.

LORENTE DON BERNARDO, in *Biography*, a Spanish painter, who was in favour at the court of Philip V., and employed to paint the infant Don Felipe. From the prospect of preferment this circumstance led forth to him, he was diverted by a decided turn for solitude; which made him fly the court, and in the sequel obtained for him the name of Pintor de las Pastoras, the painter of the shepherds, from the number of madonnas which he painted, arrayed in their garb, and surrounded by flocks. He died in 1757, at the age of 72.

LORET, in *Geography*, a town of Spain, on the S.E. coast of Catalonia; 20 miles N.E. of Mataro. N. lat. 43° 42'. E. long. 4 42'.

LOWITSCH, a town of the duchy of Warlaw; 24 miles N.W. of Rava.

LLOYD, WILLIAM, in *Biography*, an English prelate, was born at Tilehurst, in Berkshire, in 1627. His father, rector of his native place, took great pains in the education of his son, who repaid his attention by a most rapid progress in the learned languages. He was not quite twelve years of age when he was entered a student of Oriel-college, Oxford, whence he removed, in 1640, to a scholarship in Jesus-college. He was ordained in 1656, and, after the restoration, he obtained, in a very short time, considerable preferment in the church, till at length, in 1680, he was promoted to the see of St. Asaph. In 1684, he published his "History of the Government of the Church, as it was in Great Britain and Ireland, when they first received the Christian Religion." In 1688, bishop Lloyd was one of the six bishops who, together with archbishop Sancroft, were committed to the Tower for presenting a petition to king James II., against that prince's declaration for suspending the laws in favour of the Papists, which the clergy were enjoined to read in the churches. Their triumphant acquittal is well known to our readers. About the close of the same year, being known to concur very zealously in the revolution, he was made almoner to king William III., and, in 1692, was translated to the see of Lichfield and Coventry. In 1699, he published "A Chronological Account of the Life of Pythagoras, and of other famous Men, his Contemporaries: with an Epistle to the Rev. Dr. Bentley, &c." In 1699, he was translated to the bishopric of Worcester. Having, some time after this, been charged with an improper interference in the county election, he was dismissed from the office of almoner. He died at Hartlebury-castle in the year 1717, when he had attained to the ninety-first year of his age. According to bishop Burnet, Dr. Lloyd "was a great critic in the Greek and Latin authors, but chiefly in the scriptures. He was an exact historian, and the most punctual in matters of chronology. As much, however, as he was set on learning, he had never neglected his pastoral care. He was a holy, humble, and patient man, ever ready to do good when he saw a proper opportunity; even his love of study did not divert him from that." He was author of a great number of publications, the titles of which are given in the Biographia Britannica: and he left several pieces behind him in an unfinished state; among these was "A System of Chronology," out of which his chaplain, Mr. Benjamin Marshall, was said to have composed his Chronological Tables. He was supposed to have had a principal share in the "Series Chronologica Olympiadum, Istmiadum, Nemeadum, &c." published by his son at Oxford in 1700. He engaged bishop Burnet to undertake his "History of the Reformation," furnished him with a curious collection of facts and observations: and he assisted Dr. Wilkins in composing his "Essay towards a real Character, and a philosophical Language." Biog. Brit.

LLOYD, ROBERT, son of Dr. Peirson Lloyd, was one of the ushers of Westminster-school. We have already, under the article **CHURCHILL**, referred to this unfortunate young man, who is known chiefly as an author, by a poem, entitled "The Actor," which not only exhibited proofs of great judgment in the subject he was treating of, but had also the merit of smooth verification and strength of poetry. He was some time at the university of Cambridge, where he took the degree of M.A. After he quitted his place as usher at Westminster-school, he relied entirely on his pen for subsistence: being of a thoughtless and very extravagant disposition, he got deeply into debt, and was in consequence thrown into

into the Fleet prison, where he depended almost wholly on the bounty of his friend Churchill, whose kindness to him continued undiminished during all his necessities. On the death of his benefactor, Mr. Lloyd sunk into a state of despondency, which put an end to his existence in 1764. Mr. Wilkes says, that "Lloyd was mild and affable in private life, of gentle manners, and very engaging conversation. He was an excellent scholar, and an easy natural poet. His peculiar excellence was the dressing up an old thought in a new, neat, and trim manner. He was contented to scamper round the foot of Parnassus on his little Welsh pony, which seems never to have tired. He left the fury of the winged steed, and the daring heights of the sacred mountain, to the sublime genius of his friend Churchill." His works were published in 2 vols. 8vo. in 1774.

LOYD, NICHOLAS, an English divine, who was rector of St. Mary Newington, Surrey, where he died in 1680, at the age of 49. He compiled an historical, geographical, and poetical dictionary, which was printed at Oxford in 1673, in folio, and again in 1695, in 4to.

LOYD'S *Lake*, in *Geography*, a bay on the S. coast of East Florida. N. lat. 25 18. W. long. 80 50'.

LLUCH MAYER, a town of the island of Majorca, situated in the middle of a large plain, at the end of which is a mountain standing by itself, called La Randa. This town was built in the reign of James II. in the year 1300: the population amounts to about 3500 persons. The streets and houses are very regularly built; it has one parish church, consecrated to the archangel St. Michael.

LLULLA *and Chibos*, a jurisdiction of the diocese of Truxillo, in South America, lying S. of Chachapayas, and E. of the Cordillera of the Andes; low, warm, and moist, and covered with woods, so that a great part of it is uninhabited. It borders on the river of Moyabamba, which, commencing its course from these southern provinces of Peru, forms the river of the Amazons. The principal commodity of this country is tobacco, which, with a particular kind of almonds called "Andes," and a few other fruits natural to its climate, form the commerce carried on by this province with the others.

LLYN SAVADAN, or *Savahan Pool*, a lake of South Wales, in Brecknockshire; 4 miles E. of Brecknock. This lake is larger than any in Wales, except that of Bala, being two miles in length, and, in some places, one mile broad. The river Llanwy passes through this lake, and finds its way to the Wye, in a direction nearly due north. It is observed not to mix its waters with those of the lake in its passage; and the separation is understood to be so complete, that unless immediately after heavy storms, the fish of the river are not found in the lake, nor those of the lake in the river. The depth of Llyn Savadon is said to be about thirteen fathoms. The ancient tradition of a city being drowned, so universally applied to such bodies of water, is too trivial to deserve further notice.

LLYWARCH AP LLYWELYN, in *Biography*, an ancient Welsh bard, who flourished from about 1100 to 1220. Many of his pieces are in the Welsh Archaeology, and contain several historical notices of value.

LLYWELYN AP GRUFFYDD, the last sovereign of Wales, who reigned from A.D. 1254, to 1282. He was a brave prince, and resisted the ambition of Edward I. king of England a long time, but he at last fell, and with him the independence of the Welsh as a distinct nation.

LLYWELYN SIOM, an eminent poet of Glamorgan, who collected the system of Bardism, which is preserved. He presided at several meetings of the bards, and died in the year 1616.

LLYWELYN, THOMAS, a Welsh nonconformist divine of the Baptist denomination, was a native of Monmouthshire, and died in 1706. He published a history of the different editions of the Welsh bible.

LO, *Str.* in *Geography*, a town of France, and principal place of a district, in the department of the Channel, of which it is the capital, seated on the Vere, surrounded with walls, and defended by a citadel, which has some manufactures of cloth, serges, and leather. The place contains 6987, and the canton 11,707 inhabitants, on a territory of 90 kilometres, in 11 communes. N. lat. 49 7'. W. long. 1 1'.

LOACH, in *Ichthyology*, the English name of a fish, called also the *groundling*, and by the Germans the *spork* or *sworling*. It is a species of the *Cobitis*. See *Cobitis Baicalula*.

LOAD, or LODGE, in *Mining*. See LOPE.

LOAD is also used for nine duties of ore, each duty being about half a hundred weight.

LOAD, *Myhr*, among *Miners*. See MASTER-*load*.

LOAD, *Training a*. See TRAINING.

LOAD *Water-line*, in a *Ship*, is the deepest line of floatation, or when all her cargo is taken in.

LOADING. See CARGO and LADING.

LOADMANAGE, in *Maritime Affairs*: the hire is sometimes so called, which the pilot of a ship receives of a master, for conducting a ship up the river, or into port.

LOADSTONE. See MAGNET.

LOADSTONE, *Flating*, an instrument invented and so called by Mr. Boyle, which he used to discover whether guineas or other coins were counterfeit, by putting the instrument, with the piece of coin to be tried and fastened to the bottom of it, into a tall glass or other vessel of water: marks being so made on the slender metalline pipe, which forms the upper part of the instrument, that the hollow ball which made the lower part of it, would sink much lower, at least two inches, if the coin be true gold than if it be not: and according as the water reaches to one or other of the aforesaid marks, an estimate may be made, whether the piece of coin, if counterfeit, be made of tin, brass, copper, silver, or lead. The instrument might be applied to any coins, either of gold or silver, provided that they were of any considerable bulk. Birch's Hist. of the Royal Society, vol. iii. p. 115.

LOAM, derived from the German word *Lime*, and anciently signifying a viscid earth, in *Natural History*, a class of compound or mixed earths, composed of dissimilar particles, hard, stiff, dense, harsh, and rough to the touch, not easily ductile while moist, readily diffusible in water, and usually composed of sand and a tough viscid clay.

Hill comprehends under this class two genera. 1. The *thrausmicæ*; and, 2. The *glischromicæ*. The first are composed of sand and a less viscid clay, and are of a friable or crumbly nature; the second are composed of sand and a more viscid clay, and are of a more tough and viscid texture.

Da Costa distinguishes them by their colour into black and white, which are not acted upon by acids; yellow loams, some of which are not acted upon by acids; and other alkaline, brown loams, some acted upon by acids, to which class belongs the Windsor loam, so well known and so much used for making bricks, building furnaces, lutes, &c. a d others alkaline; and the green loams not acted upon by acids.

According to Woodward, loam consists of clay, mixed with fine sand, or of clay with a superabundance of sand; and Mr. Bergman, having analysed some loam found in the

neighbourhood of London, and considered as very excellent, found it to consist of 87 *per cent.* of a reddish-grey sand, as fine as meal, and 13 of argil. Supposing, therefore, clay to consist, as it most frequently does, of 30 *per cent.* of argil, and 70 of fine sand, we shall find, says Kirwan, that loam of the best kind contains an excess of sand amounting to 17 *per cent.*; if the excess of sand be greater, it will form what is called a *sandy loam*; if smaller, *clayey loam*. Mr. Bergman found nothing calcareous in the loam; when it contains any, it so far inclines to the nature of marle, and this *marlaceous loam* may be either *sandy* or *clayey*, according as the proportion above indicated is exceeded on either side. But loams most frequently contain also a portion of calx of iron, and this calx is more or less oxygenated; a circumstance which produces a considerable variety in the colour, and probably also in the vegetative powers of this earth: if its proportion be considerable, *vi.* 4 or 5 *per cent.* they often contain also some proportion of vitriolic acid. The colour of loam frequently proceeds from that of the calces of iron contained in it, but more frequently from its sandy part. Gravel, which is a coarser sort of sand, either of a calcareous or siliceous nature, is often mixed with loams, and also pebbles, whence new distinctions arise of importance to agriculture. Kirwan's *Elem. of Mineralogy*, vol. i. See **MOULD** and **SOIL**.

LOAM is also used for a sort of mortar made of this earth, by tempering it with water, straw, &c.

LOAMY SOIL, in *Agriculture*, that sort of soil into which loam enters in a considerable proportion. These soils are distinguished by many different names and colours. See **SOIL**.

LOAN-BANKS, or *Lending-houses*, establishments which may be traced to an ancient origin, formed and supported by humane persons, with a view of lending money to the poor for a certain period, on pledges, without interest. Thus, we are told, the emperor Augustus converted into a fund the surplus of the money which arose to the state from the confiscated property of criminals, and lent sums from it, without interest, to those who could pledge value equal to double the amount. (Suet. Vit. Augusti, cap. 41.) Tiberius also advanced a large capital, from which those were supplied with money for three years, who could give security in lands equivalent to twice the value. (Suet. Vit. Tiberii, c. 48. Tacit. Annal. vi. 17. Dio Cassius, c. viii. 21.) Alexander Severus reduced the interest of money by lending money at a low rate, and advancing sums to the poor without interest to purchase lands, and agreeing to receive payment from the produce of them. (Zel. Lamprid. Vit. Alex. Severi, cap. 21.) These examples of the ancients were followed in modern Italy. In order to collect money, the popes conferred upon those who would contribute towards that object many fictitious advantages, which at any rate cost them nothing. At first, money was lent to the poor for a certain time without interest, provided they could deposit pledges of proper value. At length the pontiffs resolved to allow the lending-houses to receive interest, not for the whole capitals which they lent, but only for a part, merely that they might raise as much money as might be sufficient to defray their expences. In process of time, it was thought proper, for the purpose of their having sufficient stock in hand, to give to those who should advance them money a moderate interest, which was prudently concealed by blending it with the unavoidable expences of the establishment. The lending-houses, therefore, gave and received interest. But in order to avoid the odious name, the interest that was received was said to be "pro indemnitate;" and this is the expression made use of in the papal bull. The pope declared

the holy mountains of piety, as they were called, to be legal; and threatened those with his vengeance who dared to entertain any farther doubts on the subject. All the cities now hastened to establish lending-houses; and their example was at length followed in other countries. The origin of lending-houses, in the strict sense of the term, is referred to the time of pope Pius II. or Paul II., who filled the papal chair from 1454 to 1471. The greater part of the lending-houses in Italy was established in the fifteenth and following centuries by certain Minorites. Notwithstanding the manifest advantages with which lending-houses were attended, and though many of them had been sanctioned by the infallible court of Rome, many, but chiefly Dominicans, exclaimed against these institutions, which they did not call *montes pietatis*, but *impietatis*. As this dispute was revived with much warmth in the beginning of the 16th century, it was at length terminated by pope Leo X., who, in the council of the Lateran, declared by a papal bull, that lending-houses were legal and useful; that all doubts to the contrary were sinful; and that those who should write against them would be in a state of excommunication. The council of Trent also, by a decree, acknowledged their legality, and confirmed them. See *Mounts of Piety*. See also **LOMBARDS** and **BANK**.

LOANDA, in *Geography*, an island in the Atlantic, near the coast of Angola, about 12 miles long, and one wide, separated from the continent by a narrow channel, which forms a good harbour. The soil does not produce grain; but fruits, such as oranges, figs, &c. are plentiful. It contains seven or eight villages, and on the coast are found shell-fish, called "zimbi," used for money by the natives, like cowries in India. S. lat. 8° 50'.

LOANDA, or *St. Paul de Loanda*, a sea port town of Africa, in the kingdom of Angola, the see of a bishop, and capital of a fertile province called Loanda, in possession of the Portuguese; containing several churches and convents, and about 5000 inhabitants, of whom 1000 are whites, and the rest blacks or mulattoes. The country abounds in cattle and sheep; Indian corn, millet, manioc, and fruits. S. lat. 8° 53'. E. long. 13° 22'.

LOANGHILLY, a town of Africa, in Loango; the usual burying place of the emperor; 10 miles S. of Loango.

LOANGO, a country or kingdom of Africa, situated on the W. coast towards the Atlantic, and bounded on the N. by Benin, on the E. by Anzico, and on the S. by Congo. Its climate is hotter, but not less healthy and pleasant than that of Congo and Angola, nor is its soil less fertile. The inhabitants, instead of cultivating the land, content themselves with bread and fish, and such fruits, greens, and pulse, as the soil naturally produces. Cocoas, oranges, and lemons are not much cultivated; but sugar-canes, cassia, and tobacco, as well as the palm, banana, cotton and pimento trees, grow here plentifully. They have also a great variety of roots, herbs, fruits, grain, and other vegetables, of which they make bread, and which they use for food. They have few quadrupeds for domestic use except goats and hogs, but poultry and various sorts of game are abundant: among the wild beasts they have the zebra, and a great number of elephants, whose teeth they exchange with the Europeans for iron. The natives, who are called Bramas, are tall, stout, and well formed, and though formerly cannibals, are of late much improved in their manners. They practise circumcision, are addicted to trade among themselves, and are friendly and hospitable in their mutual intercourse. They are fond of females and jealous of their wives. Their dress consists chiefly of cloth manufactured by

by themselves; and they are fond of ornaments about their necks, legs, and wrists, which they form of beads of coral, ivory, shells of a beautiful hue, chains of copper, tin, or iron, obtained from Europe. Polygamy is allowed among them; their rich men having 12 or more wives, and the poor not fewer than three. Of a Supreme Being, their notions are very imperfect and confused. Their worship is addressed to demons, domestic and rural; and to these they ascribe great influence. To their monarchs they attribute a kind of supernatural and unlimited power. The foreign commerce of the country consists chiefly in slaves; and they likewise sell considerable quantities of ivory, tin, lead, iron, and copper. The kingdom of Loango, separated from Congo, of which it was formerly a part, is divided into four principal provinces, *viz.* Lovangiri, Louango-Mongo, Kilongo, and Piri. The first is fertile and well inhabited; the second, lying N.E. of the former, is spacious and productive, particularly of palm-trees, the oil of which they extract in great quantities; and the inhabitants employ themselves in working a variety of linen and cloth; the third is a maritime province, and is the largest and the most populous of the four; its plains are extensive and fertile, and they are sheltered at a distance by ridges of high mountains; the trade of the inhabitants, who are rude and unpolished, consists in elephants' teeth; the last province, north of Kilongo and Louango-Mongo, is low and flat, but abounds with variety of fruits and other trees, and is well peopled and cultivated; the inhabitants are peaceable and strangers to war. They have plenty of cattle, and of wild and tame fowl, and take great pleasure in hunting. Their food is supplied by the game they take, and the milk of their cattle. In all these provinces there are many towns and villages.

LOANGO, a city of Africa, and capital of the above-mentioned country, situated on a river, which forms a bay at its mouth, about six miles from the coast of the Atlantic. The natives call it "Borai," or "Boori." It is very spacious and airy, as the houses are not contiguous to one another. The streets are wide and clean, and lined with palm-trees, bananas, and bacavas, which shelter the houses both before and behind. The palace adjoins to a square in the centre of the city, and of itself forms another square, one and a half mile in compass, surrounded with a palisade of stately palm-trees. Besides the public buildings of which it consists, it is occupied by the houses of the king's women, ten in number, and each capable of accommodating seven or eight of them. At a small distance is a market place, which supplies purchasers every day with meal, poultry, fish, wine, corn and oil, as well as palm-cloth; and in the market-place is a famous temple and mokisso, or idol, called "Mokisso a Loango," which has been held in great veneration both by the kings and their subjects. The houses are of an oblong shape, flat in the middle part of the roof, and each house is fenced round with a hedge of palm-twigs, canes, or bulrushes.

The bay of Loango, though upon the whole good, is incommoded by a bank on the N. side of its entrance, running half a league along the coast, and having not more than two and a half fathoms of water. The numerous and large rivers that flow from the continent, occasion such rapid and strong currents towards the north during almost the whole year, that it is very difficult to weather them, and gain a southern course. The only months in which they may be stemmed with safety are January, February, March, and April; during the other months of the year the currents flow so strong, that even coasters must keep at least 10 or 12 leagues off the land. S. lat. $4^{\circ} 40'$. E. long. $10^{\circ} 25'$.

LOANGO, a river of Africa, which runs into the Atlantic, S. lat. $10^{\circ} 30'$.

LOANO, or LOVANO, a town of Genoa, near the sea; six miles S.S.W. of Finale.

LOANS, GOVERNMENT. See STOCKS.

LOAR, or LOARRE, in *Geography*, a town of Spain, in Aragon; 13 miles S. of Jaca.

LOARDEGA, a town of Hindoostan, in Bahar; 40 miles S. of Palamow.

LOBARIA, in *Natural History*, a genus of the Vermes mollusca class and order: Body lobate, convex above, flat below. There is only one species, *viz.* quadriloba, characterized as having a tail with four lobes. It is found in the northern seas.

LOBATUM FOLIUM, in *Botany*, a leaf the outline of whose segments is curved. See LEAF.

LOBAU, in *Geography*, a town of Prussia, in the territory of Culm; 44 miles E. of Culm.

LOBAU, or *Liele*, one of the most ancient towns in the province of Upper Lusatia, containing two churches, three chapels, an hospital, and a Latin school, and trading chiefly in linen and thread; 10 miles S.W. of Gorlitz. N. lat. $51^{\circ} 7'$. E. long. $14^{\circ} 46'$.

LOBB, THEOPHILUS, in *Biography*, a physician of considerable reputation about the middle of the last century, practised his profession in London, and left several works on medical topics. He died on the 19th of May, 1763, in the eighty-fifth year of his age. The following are the titles of his publications. "Treatise of the Small-pox," London, 1731, 1748, 8vo.; which was translated into French in 1749. "Rational Method of curing Fevers, deduced from the Structure of the Human Body," *ibid.* 1734, 8vo.; in this work he adopted the doctrines of Boerhaave. "Medical Practice in curing Fevers," *ibid.* 1735, 8vo. "A Practical Treatise on painful Dilempers, with some effectual Methods of curing them," *ibid.* 1739. "A Treatise on Solvents of the Stone, and on curing the Stone and the Gout by Aliments," *ibid.* 1739. This work passed through several editions, and was translated into Latin and French. The author considered the matter of urinary calculi and of gout as of an alkaline nature, and vegetable acids as the remedy. "Letters concerning the Plague and other contagious Dilempers," *ibid.* 1745. "A Compendium of the Practice of Physic," *ibid.* 1747. Besides these works, he was the author of several papers printed in the Gentleman's Magazine, and of one or more tracts on religious subjects in the latter part of his life. Eloy Dict. Hist. Gent. Mag.

LOBBY, in *Architecture*, is a small hall or waiting-room: it is also an entrance into a principal apartment, where there is a considerable space between that and a portico or vestibule, and the length or dimensions will not allow it to be considered as a vestibule or an anti-room. See ANTI-CHAMBER.

LOBBY, in a *Ship*, an apartment close before the captain's cabin.

LOBBY, in *Agriculture*, a sort of narrow confined place, formed either by hedges and trees, or other kinds of fencing, near to the farm-yard, for the purpose of confining livestock. It is observed by Mr. Marshall, in his *Minutes of Agriculture in the Midland Counties*, that "every farmery ought to have a lobby and a cross appending to it, serving as a double fence; thereby preventing stock from running over, poaching, and injuring the farm; the latter for calves, a saddle horse, and invalids. He found the convenience of a lobby in Surrey, and the want of one in Norfolk, and in this

this district; he can foresee the use of that which he is forming, with a screen of planting; embosoming the entire farmery, in such a manner as to shelter it effectually from the north and east winds."

LOBE, or LOBUS, in *Anatomy*, an epithet applied to the more or less separate parts, of which the glands of the body are composed. Thus we have lobes of the brain, lungs, liver, &c.

LOBE is also used for the tip of the ear; which is more fat and fleshy than any other part thereof.

Du Laurent says, that the word *lobe*, in this last sense, comes from the Greek, *λοβος*, to *shame*, or *be ashamed*; this part of the ear being said to blush when the person is ashamed.

LOBE is also used in speaking of fruits and grains.

Thus the bean consists of two equal parts, called lobes, which compose the body thereof, and are encompassed with the other skin. And all other grains, even the smallest, are divided, like the bean, into the two lobes, or equal parts; as Dr. Grew has shewn in his *Anatomy of Plants*. See LOBUS.

LOBEDA, in *Geography*, a town of Germany in the principality of Eisenach; three miles S.S.E. of Jena.

LOBEDIUN, a town of Russia, in the government of Tambov; 100 miles W.N.W. of Tambov. N. lat. 53° 28'. E. long. 38° 50'.

LOBESUN, a town of Westphalia, in the duchy of Magdeburg; 25 miles N. of Leipzig.

LOBEIRA, VASCO, in *Biograph*, author of "*Amadis of Gaul*," was born at Porta about the middle of the fourteenth century. He was knighted upon the field of battle at Aljubarrota by king Joao I. in the year 1386, and died at Elvas, where he possessed a good estate. According to Mr. Southey nothing more has been collected by the Portuguese biographers of Lobeira. It has been questioned whether he was the author of the *Amadis de Gaul*, and whether that poem was not written in France rather than in Portugal; to which the translator replies, "Some weight must be allowed to the authority of the Portuguese writers, who have all, with the exception of Cardoza, attributed it to Lobeira as an original production." "The romance," he farther adds, "is not older than Lobeira's age; for it refers to the English claim upon the crown of France, and represents Windsor as the most splendid court, and the king of England as the most powerful king in Christendom. It was written in a country remote from England; for Windsor is called an island, and the adventures who cross from France make Bristol their port. Many other such instances of geographical ignorance could be mentioned; mistakes which might easily be made by a Portuguese, but not by a Frenchman. It was written in Portugal, for many of the names are Portuguese. Better proofs of time and place cannot be required." Of the poem Mr. S. says, it may be safely affirmed that it contains nothing which, in the age in which it was written, would be regarded as impossible, scarcely any thing that would be thought exaggerated. The actions of Amadis, and the importance of a single chief, would not appear incredible to a people who had then living among them their own hero, Nuno Alvares Pereira, whose military exploits were as extraordinary, and as important to his own character. To a nation who knew this man, and knew also that it was chiefly owing to his courage that they existed as a separate people, the character of Amadis would not appear exaggerated. Amadis has been considered as the model of a perfect knight. "Truly," says sir Philip Sidney, "I have known men, that even with reading Amadis de Gaul, which,

God knows, wanteth much of a perfect poesie, have found their hearts moved to the exercise of courttesy, liberality, and especially courage."

LOBEL, or L'OBEL, MATTHIAS DE, a botanist nearly contemporary with Clusius, whose wooden cuts, for the most part, re-appeared in his works, was not, as some have thought, an Englishman, but born, in 1538, at Lisse in Flanders, where his father practised in the law. He acquired in his youth an ardent love of plants, and had good opportunities of gratifying his taste, and advancing his knowledge, at Montpellier, where he studied physic under the learned Rondelet, or Rondeletius. During his residence there, he found opportunities of making some botanical excursions over the south of France. At Narbonne he became acquainted with Pena, afterwards his fellow labourer in the *Adversaria*, the first edition of which was published, in small folio, at London, in 1570, and dedicated to queen Elizabeth. The few cuts dispersed through this volume are mostly original, but inferior in style and accuracy, as well as in size, to those of Clusius. Before the publication of the *Adversaria*, our author had extended his travels to Switzerland, the Tyrol, some parts of Germany and Italy; had settled as a physician at Antwerp, afterwards at Delft; and had been appointed physician to the illustrious William prince of Orange, and to the States of Holland. Dr. Pulteney has not been able to ascertain the time of Lobel's removal to England, but justly concludes it to have been before 1750; indeed, most probably, some years earlier, as he mentions in this edition of the *Adversaria*, p. 92, having long ago received from Dr. Turner seeds of the Sea Kale, *Gracile maritima*, of which he there exhibits an indifferent cut, mentioning it as a plant whose flowery tops might be eaten, though much inferior to the cultivated kinds of the same tribe. It appears by this, that the young sprouts, now known to be so excellent for the table, had not then been tried.

The aim of the authors of the *Adversaria* was to investigate the botany and *materia medica* of the ancients, and especially of Dioscorides. They therefore frequently criticise Matthioli, the most celebrated commentator of the Greek writer, for it is scarcely possible for different people to pursue this intricate and obscure path long without disagreement. Indeed half a score commentators on the plants of Dioscorides might all exercise their ingenuity, in most cases, with equal skill, without any body being able to decide which of them was nearest the truth. The *Adversaria* was reprinted at Antwerp in 1576, the dedication being, of course, there suppressed. New title-pages had been printed to help the sale of the original, in 1571 and 1572. Some copies of the Antwerp impression appear to have been made up into a new edition at London in 1605, an ample *Pharmacopoeia*, the foundation of which was from Rondeletius, being prefixed, and an appendix to the *Adversaria* subjoined. This volume is dedicated to Edward lord Zouch, whom Lobel had attended, on his embassy to Denmark, in 1592, and he calls himself, in the title, botanist to king James I. Dr. Pulteney observes, after Haller, that this work exhibits some traces of a natural distribution of plants, inasmuch at least as they are thrown together into a number of tribes or orders, according to their habits or flowers; but this is done without any remarks, and with so little precision, that it can only be said the method of Lobel is better than that of Dodonæus, in which there is no consistent principle at all. His work is much more valuable for the various remarks which it contains, and for the accounts of new plants, discovered by himself in England or elsewhere. On the subject

of British natives indeed, Ray accuses him of having made several mistakes, from having trusted too much to his memory.

The *Stirpium Historia* of this author, a volume in small folio similar to his *Adversaria*, was published at Antwerp in 1576. This is much less copious in matter, the pages being mostly occupied with wooden cuts, which are those of Clusius, borrowed for the present occasion by the printer, Plantin. An impression of these cuts, of an oblong shape, was struck off, with names only, in 1581, and another in 1591. Linnæus possessed both. This publication is in very general use, and well known by the title of Lobel's *Icones*. It is, when complete, accompanied by an index in seven languages.

Lobel seems to have had a very large work in contemplation, which he intended to call *Stirpium Illustrationes*. This he did not live to complete. A fragment of it was published in quarto, without plates, by Dr. W. How, in 1655, making 170 pages, besides a caustic preface of the author, aimed chiefly at Gerarde, whom he doubtless comprehends among the "*prodii pharmaceutii*," charged with robbing the most experienced physicians of their honours. The body of the work is interperfed with notes of Dr. How's against Parkinson, who is said to have made dishonest use, in his *Theatrum Botanicum*, of some papers of Lobel, that fell into his hands. It must be allowed that such authors are justly censured for translating and interweaving descriptions, remarks, and places of growth, from foreign works, which apply to the plants of other countries. This fault is not dissimilar from what we have censured in a more modern writer; see LIGHTFOOT, and the botanical article FLORA. But the style of Lobel's preface is properly reprobated by Dr. Pulteney, who blames him for this gross abuse of Gerarde after his death, though he had formerly on every occasion extolled him. The botanical contents of this fragment are, however, very honourable to Lobel, for the number of new plants therein mentioned.

Our author laboured to an advanced age in the pursuit of his favourite study, and procured from his correspondents abroad, many new plants for the gardens of his friends. He had the superintendence of a garden at Hackney, cultivated at the expense of lord Zouch; and appears to have resided, in the decline of life, at Highgate, where he had a daughter, married to a Mr. James Coel. His wife is recorded as having assisted him in his botanical researches. He died in 1616, aged 78. Lobel's works. Haller's Bibl. Bot. Pulteney's Sketches.

LOBEL, a drolling, blind, fiddling, Bohemian Jew, the first master, on the violin, of the celebrated Benda, first violin to Frederic II. king of Prussia, during the whole reign of that musical prince. See BENDA, and Burney's German Tour, vol. ii.

LOBELIA, in *Botany*, so called in honour of Matthias de Lobel; see that article. The plant to which Plumier originally applied the name, is now the *Scavola* of Linnæus. When the latter, at the suggestion of Jacquin, discovered that he and other botanists had confounded, under this original *Lobelia*, a vast number of species generically distinct from it, but which were then become much better known than itself by the name in question, he judged it much less inconvenient to keep this name for them, and to give the genus of Plumier a new one. It is hoped the same measure would be adopted, should any botanist ascertain the original *Magnolia* of Plumier, to be really distinct in generic characters from all the other species so called, of which there is said to be some suspicion.—Linn. Gen. 456. Schreb. 596. Willd. Sp. Pl. v. 1. 937. Mart. Mill. Dict. v. 3. Sm.

Fl. Brit. 242. Ait. Hort. Kew. ed. 2. v. 1. 356. Juss. 165. Lamarek Illustr. t. 724. (Rapuntium; Tournef. t. 51. Gærtn. t. 30.)—Class and order, *Pentandria Monogynia*. (Syngenesia Monogamia; Linn.) Nat. Ord. *Campanaceæ*, Linn. Juss.

Gen. Ch. *Cal.* Perianth of one leaf, surrounding the germen, in five deep, nearly equal, withering segments; the two superior ones most directed upwards. *Cor.* of one petal, irregular, slightly ringent; tube cylindrical, longer than the calyx, divided lengthwise at the upper side; limb in five deep lanceolate segments, of which the two uppermost are smallest, most reflexed, and most deeply separated, constituting the upper lip; the three lowermost more spreading, and generally largest. *Stam.* Filaments five, awl-shaped, the length of the tube of the corolla, united upwards; anthers united into an oblong, somewhat oblique and curved, cylinder, separating into five parts at the base. *Pist.* Germen more than half inferior, pointed; style cylindrical, the length of the filaments; stigma obtuse, bifid. *Peric.* Capsule ovate, or roundish, of two or three cells, and two or three valves, bursting at the top, encompassed by the calyx; the partitions contrary to the valves. *Seeds* numerous, minute, smooth. *Receptacle* conical.

Eff. Ch. Calyx in five segments, crowning the germen. Corolla of one petal, irregular. Anthers cohering, incurved. Capsule half inferior, of two or three cells.

So much uncertainty attends the characters of some plants which have been referred to *Lobelia*, that we can hardly guess with any degree of correctness at the number of species. The 14th edition of the *Systema Vegetabilium* exhibits the latest view that Linnæus or his son took of the genus, and there 42 species are enumerated, of which however the 21st, *levigata*, and 25th, *surinamensis*, are one and the same, and the 40, which is *parvifolia* (not *parviflora*) of Bergius, is *Lightfootia oxycochoides*; see LIGHTFOOTIA. Three others, *Phytoloma, luteola*, and *volvulidis*, go along with *Cyphia, cardamines*, and *incisa*, of Thunberg's Prod. 39, to form the genus *CYPHIA*, Berg. Cap. 173. Willd. Sp. Pl. v. 1. 952. Ait. Hort. Kew. ed. 2. v. 1. 362, of which we have spoken in its place, and which perhaps, when we consider its having five distinct petals, with linear and straight, as well as separate, anthers, may be allowed to constitute a tolerably good, though not a very natural, genus. Willdenow, retaining this genus, has still 48 *Lobelia*, disposed in three, not very correct, sections, of each of which we shall mention a few examples. Two species only are natives of Britain.

SECT. 1. *Leaves entire.*

L. Dortmannia. Water Lobelia. Linn. Sp. Pl. 1318. Eng. Bot. t. 140. Fl. Dan. t. 39. (Dortmannia lacutris, floribus sparsis pediculis; Rudd. Act. Upsl. for 1720. 67. f. 2. Gladiolus lacutris; Ger. em. 105.)—Leaves linear, entire, of two parallel cells. Stem nearly naked.—Found in the clear shallow parts of lakes, in the colder parts of Europe, growing in the pure gravelly bottom, and raising the flowering part of its stem only above the surface. The root is perennial, composed of numerous, long, white, simple fibres. Herb smooth, milky when wounded. Radical leaves numerous, entirely immersed, linear, recurved, nearly cylindrical, though flattish on the upper side, obtuse, two or three inches long, very remarkable for confiding internally of two cavities, separated by a longitudinal partition. Stem solitary, erect, round, hollow, almost leafless, bearing a loose cluster of pendulous blue flowers in July and August, often overflowed by sudden floods. Clusus received this plant from a Mr. Dortmann, and has represented it in his *Cure Posteriores*, 40; but the cut, reprinted in Johnson's edition

LOBELIA.

edition of Gerard, is justly criticised by Rudbeck; for the germen is represented superior, the stamens totally erroneously, and the corolla by no means well.

Sect. 2. *Stem erect. Leaves cut or serrated.*

L. Tupa. Willow-leaved Lobelia. Linn. Sp. Pl. 1318. (*Rapuntium spicatum*, foliis acutis, vulgò *Tupa*; Feuille. It. v. 2. 739 t. 29.)—Leaves decurrent, lanceolate, finely serrated. Cluster spiked. Stem hollow. Feuillée gathered this plant on the mountains of Chili, in 37 degrees south latitude; (not 65, as in Bot. Mag. 1325.) He speaks of it as one of the most active of poisons, the smell of the flowers causing severe vomitings, and the milk of the plant, if by any accident it touches the eyes, occasioning blindness. The root is a foot and a half long, apparently perennial. Stem as tall as a man, hollow, five-sided, terminating in a spike of large, blood-red, stalked flowers, with a lanceolate bractea at the base of each partial stalk. Leaves decurrent for the space of 2½ inches, the rest of their length, about seven inches, elliptic-lanceolate, acute, finely serrated, minutely downy; reticulated with veins beneath. Feuillée describes the serratures, but does not figure them.

L. gigantea. Gigantic Lobelia. Sims in Curt. Mag. t. 1325. (*L. Tupa*; Dryand. in Ait. Hort. Kew. ed. 2. v. 1. 357.)—Leaves sessile, lanceolate, finely serrated. Flowers axillary, solitary, stalked. Stem shrubby, solid.—Our specimen of this plant was gathered by Mr Menzies near Valparaiso in Chili, in latitude 33½ south, whence Dr. Brandt is said also to have brought seeds to Messrs. Lee and Kennedy, in whose conservatory the shrubby stem is 15 or 16 feet high, solid, and round. Leaves sessile, lanceolate, more or less serrated, scarcely reticulated beneath. Flowers dull orange, on simple, solitary, axillary stalks, much shorter than the leaves. These characters have, in our opinion, justified Dr. Sims in making it distinct from the last, to which it seems moreover inferior in virulence.

L. affurgens. Purple Jamaica Lobelia. Linn. Sp. Pl. 1321. Andr. Repof. t. 553. Leaves elliptic-lanceolate, tapering at both ends, sharply toothed, somewhat decurrent. Cluster compound, terminal, downy.—Native of Jamaica. It flowers in the latter part of summer in our stove, making a handsome appearance, though its purplish colour is less striking than the scarlet of the following.

L. cardinalis. Scarlet Lobelia. Linn. Sp. Pl. 1320. Curt. Mag. t. 320.—Leaves broadly-lanceolate, serrated. Spike terminal; the flowers turned one way.—Native of North America. Hardy in our gardens, in a strong moist soil, flowering in August and September. The root is perennial. Stems three feet high, leafy. Flowers of a moist rich and vivid scarlet.

L. urens. Acid Lobelia. Linn. Sp. Pl. 1321. Curt. Lond. fasc. 6. t. 63. Engl. Bot. t. 953.—Stem nearly erect. Lower leaves obovate, finely toothed; upper lanceolate, serrated. Flowers racemose.—Native of France, Spain, and some few parts of Devonshire, on gravelly bushy commons. This is perennial, flowering in August and September. Its habit is slender, delicate, and smooth. Stem 18 to 24 inches high, milky. Leaves feathered. Flowers small, blue, numerous, in long weak clusters. Segments of the calyx bristle-shaped, rough, as long as the tube of the flower.

Sect. 3. *Stem mostly decumbent. Leaves somewhat cut.*

L. Laurentia. Italian Annual Lobelia. Linn. Sp. Pl. 1321. (*Laurentia annua minima*, flore ceruleo; Mich. Gen. 18 t. 14.)—Stem prostrate, branched. Leaves lanceolate-oval, crenate. Stalks solitary, axillary, single-flowered, very long.—Native of Italy. A little delicate annual species, sent to Kew in 1778, by M. Thoun. It blof-

fomed in the green-house in July. The flowers are blue, very minute.

L. setacea. Bristle-stalked Lobelia. Sm. Prodr. Fl. Græc. Sibth. v. 1. 145. Fl. Græc. ined. t. 221. (*L. tenella*; Bivon. Cent. 1. 53. t. 2.)—Radical leaves spatulate, wavy; those of the stem bristle-shaped. Stems perfectly simple, single-flowered, erect.—Native of boggy places in Crete, Cyprus, and Sicily. Root annual. Leaves spatulate, on long slender radical stalks, chine, wavy, smooth, somewhat like those of a daisy. The little slender stems bear two small bristle-like leaves, and one elegant blue flower. The stems appear to be erect, but on account of the close affinity of the present species to *L. Laurentia*, they cannot be distinguished. They are indeed confounded by Willdenow, and by Boeckner in his t. 27, where both are well drawn, as one species. Our *setacea* is *Rapuntium creticum minimum*, bellidis folio, flore maculato; Tourn. Cor. 9.

L. lutea. Yellow Lobelia. Linn. Sp. Pl. 1322. Curt. Mag. t. 1319.—Stems ascending. Leaves lanceolate, serrated. Flowers reversed, in short spikes.—Native of the Cape of Good Hope. It flowers here in the green-house, and is remarkable for its golden flowers, whose position, as Dr. Sims observes, is reversed, their tube very short, and the posture of their two smaller segments, arched over the stamens, very peculiar.

Numerous new species of *Lobelia* are to be added to Willdenow's list, from the discoveries in New Holland. These are usually of a smooth delicate habit. See Labillardiere, t. 71—74, and Brown's *Prodronus*, v. 1. 562. The latter defines 20 species from that country, none of them in Willdenow.

LOBELIA, in Gardening, comprehends plants of the herbaceous and under-shrubby perennial kind, of which the species usually cultivated are the scarlet lobelia, or cardinal's flower (*L. cardinalis*;) the blue lobelia, or cardinal's flower (*L. siphilitica*;) the long-flowered lobelia (*L. longiflora*;) the pine-leaved lobelia (*L. pinifolia*;) and the bladder-podded lobelia (*L. inflata*.)

Method of Culture.—The first and second kinds may be increased by seed, cuttings of their stalks, and parting the roots. The seeds should be sown in autumn, or early in spring, in a warm border, or in pots or boxes, so as to be moved to different situations in different seasons, to have shelter from frost, and shade from the mid-day sun in summer. Those sown in autumn generally come up more freely the following spring than those which are sown in that season. They should have shelter in hard frosts, either under a frame or awning of mats, but be fully exposed in mild weather, giving occasional waterings in the spring and summer. When the plants have attained two or three inches growth, they should be pricked out in separate small pots of rich earth, giving water, and placing them in the shade till fresh rooted, repeating the waterings occasionally in hot dry weather, and shifting them into larger pots as they may require; in winter moving them into a frame to have occasional shelter from inclement weather; and in the spring following some of them may be turned out into the full ground about March, when they will flower the ensuing summer. Some should also be retained in pots to be moved under shelter in winter, as a reserve in case those in the open air should be killed by the frost.

And as the plants generally flower in the greatest perfection the first and second year of their blowing, it is proper to raise a new supply of them every year or two in order to have them flower in the utmost perfection every year.

Where the second mode is in use, the cuttings of the young stalks should be divided into lengths of five or six inches, and

and be planted in an easterly border, two parts deep, being covered down with hand-glasses, and watered occasionally. They mostly emit roots, and form young plants in a month or six weeks, when the glasses should be taken away, and the plants managed as the others.

And these hardy forts sometimes afford off-sets from their sides at bottom, which may be separated in autumn, and potted for young plants, being managed as the seedlings.

Each of the three last forts may also be raised by seeds procured from abroad, which should be sown in pots of light sandy earth in the autumn, and plunged in the bark-bed; and when the plants are three inches high, planted in separate pots, being replunged in the bark-bed, giving water and occasional shade till they are fresh rooted. They must remain constantly in the hot-house, and have frequent moderate waterings given them.

The first two forts have a fine appearance in the borders and clumps of pleasure-grounds, where they will succeed when protected in winter from frosts and other injuries.

And all the tender forts afford a fine variety in hot-house collections.

LOBELIA *Siphilitica*, *Blue Lobelia*, or *Cardinal Flower*, in the *Materia Medica*, is a native of Virginia, and flowers from August till October. Every part of the plant abounds with a milky juice, and has a rank smell. The root, which is the part prescribed for medicinal use, in taste resembles tobacco, and is apt to excite vomiting. It derived the appellation of *siphilitica* from its efficacy in the cure of syphilis, according to the experience of the North American Indians, who considered it as a specific in that disease, and who long kept it a secret. But the secret was purchased by sir William Johnson, and has been since published by different authors. The method of employing this medicine is stated as follows: a decoction is made of a handful of the roots in three measures of water. Of this half a measure is taken in the morning fasting, and repeated in the evening; and the dose is gradually increased till its purgative effects become too violent, when the decoction is to be intermitted for a day or two, and then renewed till a perfect cure is effected. During the use of this medicine, a proper regimen is to be enjoined, and the ulcers are also to be frequently washed with the decoction, or if deep and foul, to be sprinkled with the powder of the inner bark of the New Jersey tea-tree (*Ceanothus Americanus*.) Although the plant thus used is said to cure the disease in a very short time, yet the antisyphilitic powers of the lobelia have not been confirmed by any instances of European practice. Woodv. Med. Bot.

LOBENSTEIN, in *Geography*, a town of Saxony, and chief place of a lordship, on the Lemnitz, in the county of Reussen; 26 miles N. of Bayreuth. N. lat. 50° 21'. E. long. 11° 50'.

LOBERA, a town of Spain, in Aragon; 20 miles W.S.W. of Jaca.

LOBES, a town of Bohemia, in the circle of Boleslaw; 9 miles W.N.W. of Jung-Buntzel.—Also, one of the smaller Canary islands, between Lancerotta and Fortaventura. N. lat. 28° 50'. W. long. 13° 40'.

LOBES of the Ear, *Boring of*. To bore or perforate the lobes of the ears, you must first of all mark the place with a spot of ink. About the middle is generally the best situation for the aperture. The lobe of the ear is to be extended with the left fore-finger and thumb, and the perforation made exactly where the dot is, with a large common sewing needle. The ring being now introduced, and gently moved about a few times every day until the margin of the puncture is healed, will hinder the little hole

from becoming impervious. See *Hist. of Surgery*, vol. ii. p. 5.

LOBINEAU, GUY-ALEXIS, in *Biography*, was born at Rennes in 1666, entered among the Benedictines of St. Maur in his seventeenth year, and devoted his life and talents to study. He died in the year 1727. His principal works are "L'Histoire de Bretagne," two vols. folio, to which he gave the finishing hand, it having been composed by Father le Gallois: "L'Histoire de Deux Conquêtes d'Espagne par les Maures," which is a translation from the Spanish, and is probably little more than a romance. "Histoire de Paris," 5 vols. folio: this work was begun and much advanced by father Febblin, and put into the hands of Lobineau to finish. "L'Histoire des Saints de Bretagne." He translated the "Strategems of Polyannus" from the Greek, and made versions of some of Aristophanes' comedies. Moreri.

LOBITH, in *Geography*, a town of the duchy of Clèves; 5 miles N.W. of Emmerick.

LOBKOWITZ, PRINCE, in *Biography*, deserves well to be remembered among illustrious dilettanti in music. He was in England at the same time as the mysterious count St. Germaine, from 1746 to 1748; and from congenial tastes in music, they were seldom asunder. This prince, who was uncle to the charming and accomplished madame Thune at Vienna, was no less remarkable for his musical talents, than the beauty and dignity of his person. We have seen and heard at Vienna many of his musical compositions, chiefly for the German flute, which, from their correctness, would not have disgraced an eminent professor. The termination of this gallant prince's career was melancholy: after distinguishing himself in the army, as well as by his accomplishments and good taste in the fine arts, he lost his faculties; and was seized with a dark and gloomy despondency, in which he lingered during the remainder of his miserable existence.

LOBKOWITZ, BOLESLAS DE HASSENSTEIN, *Baron de*, a Bohemian nobleman and man of letters. After travelling into various countries, and bearing arms with reputation, he embraced the ecclesiastical state, and was employed in public affairs. He died in 1510. His poems were first printed at Prague in 1563, and again in 1570. Moreri.

LOBLOLLO BAY, in *Geography*, a bay of the island of Antigua, on the W. coast.

LOBLOLLY-BAY, in *Botany*. See *GORDONIA*.

LOBLOLLY, a sea-faring dnb, otherwise called *luggs*.

LOBLOSOW, in *Geography*, a town of Poland, in R. of Russia; 36 miles S.E. of Hahel.

LOBO, JEROME, in *Biography*, a Jesuit missionary, born at Lisbon in 1593, entered among the Jesuits in his thirteenth year, and in 1622 he went out as one of their missionaries to the East Indies. After passing some time at Goa, he sailed to the coast of Africa, and penetrated into Abyssinia, where he resided some years, subject to much danger and many hardships and sufferings: on his return he was shipwrecked and narrowly escaped destruction. He promoted the interest of the Abyssinian mission at Madrid and Rome, and, notwithstanding the calamities to which he had been subjected, he took a second voyage to the Indies. He returned to Lisbon in 1658, and was made rector of the college of Coimbra, where he died in 1678, at the age of 84. He was author of "An Historical Account of Abyssinia," containing much curious and valuable information. It was translated from the Portuguese language into the French by the Abbé le Grand, with additions, which translation was abridged by Dr Samuel Johnson. Moreri.

LOBO, RODRIGUEZ FRANCIS, a Portuguese poet, was born

at Estramadura. He was author of a comedy called "Euphrosyne," which is a great favourite among his countrymen. He was likewise the author of a folio volume of poems printed in 1721. Moreri.

LORO, in *Geography*, a town on the S. coast of the island of Lugon. N. lat. 13° 40'. E. long. 121° 15'.

LOBON, a town of Spain, in the province of Estramadura; 13 miles W. of Merida.

LOBOS, a small island in the Atlantic, near the coast of Africa. N. lat. 21° 20'.—Also, a small island at the mouth of La Plata river; 15 miles S.W. of Cape St. Maria. N. lat. 35°.—Also, a small island in the gulf of Mexico, on the coast of Gualeca. N. lat. 22° 28'.—Also, island in the Pacific ocean, near the coast of Peru, surrounded with rock; about twelve miles from each other, in S. lat. 6° 25' and 6° 45'. They are also called "Sea-Wolves," or "Seals' islands."—Also, a cluster of small islands in the South Pacific ocean, near the coast of Chili. S. lat. 52° 20'.

LOBOS Key, or *Sail Key*, a small island among the Bahamas. N. lat. 23° 45'. W. long. 77° 34'.

LOBRES, a town of Spain, in the province of Grenada; 7 miles N. of Motril.

LOBS, in *Mining*, are steps that ascend or descend within the mines, as flairs up to and down from a chamber.

LOBSKOL, PELANSKOL, in *Geography*, a town of Russia, in the government of Olonetz, near the lake Sig; 52 miles W.N.W. of Povenetz.

LOBSTADT, a town of Saxony, in the circle of Leipzig; 10 miles S.S.E. of Leipzig.

LOBSTER, in *Zoology*, a species of the squilla, according to some writers; but in the Linnaean system a species of the cancer. See *CANCER Gammarus*.

LOBULUS, in *Anatomy*, a diminutive from *lobus*, is a small lobe, and denotes more minute divisions of glandular bodies, than those which form lobes; as, for example, the lobuli of the lungs. Lobulus auris is that part of the external ear which is pierced for ear-rings. (See *EAR* and *LOBES*) Lobulus Spigelii is a small portion of the liver. See *LIVER*.

LOBULUS, in *Botany*, a little lobe, a term suggested by Dr. Smith, for what has usually, but erroneously, been called the auricle, in some species of *Jungermannia*: see that article.

LOBURG, in *Geography*, a town in the duchy of Magdeburg; 22 miles E. of Magdeburg.

LOBUS, in *Botany*, a lobe, a principal division of a leaf, the margins of which are in some degree rounded. The term is also used for the divisions of the petals, or any other suitable part. A capsule is sometimes said to be lobed, there being scarcely any other way of describing, in English, a triaccous or tetraccous fruit.

LOCAGNANO, in *Geography*, a town of the island of Corsica; 12 miles N. of Bastia.

LOCAL, something supposed to be tied or annexed to some particular place.

Thus, in *Law*, a thing is said to be local, *i. e.* annexed or fixed to the freehold. An action of trespass for battery, &c. is transitory, not local; that is, it is not necessary, that the place where battery was committed should be set down as material in the declaration; or if it be set down, the defendant cannot traverse it, by saying, he did not commit the battery in the place mentioned in the declaration, and to avoid the action.

LOCAL, *Physic*. See *CHORE*.

LOCAL Colour, a technical term in the art of *Painting*, wherein, however, it has two meanings. The one is the

actual colour of an object intended for imitation; the other alludes to that colour in conjunction with the situation the object which possesses it fills in a picture; wherein it must be more or less subject to shadows, and the regulations of aerial perspective; which latter diminishes the force of colours according to their distance from the eye, by the intervention of that of the atmosphere.

It is a difficult but a necessary part of the art to maintain local colours in objects and yet throw them into shade, and still more to support it in the gradations from light to dark. A degree of cool colour intervenes in nature, the admixture of which in the substances used in painting too often destroys the local or real colour, so that painters have often had recourse to their shadow-colour alone, and by mixing that with the positive colour, trust to its effect for harmony, and omit the greater delicacies of nature. But Titian, Vandyke, Correggio, and sir J. Reynolds, ventured to attempt the full support of the colour of the body, and succeeded, particularly the two latter, whom the artist will do well to study on this head.

LOCAL Customs, are those peculiar to some lordship, or other district, and not agreeable to the general customs of the country. See *CUSTOM*.

LOCAL, or *Artificial Memory*. See *MEMORY*.

LOCAL Motion. See *MOTION*.

LOCAL Problem, in *Mathematics*, is such an one as is capable of an infinite number of different solutions; because the point that is to solve it, may be indifferently taken within a certain extent; *e. gr.* any where in such a line within such a plane figure, &c. which is called a *geometrical locus*.

A local problem may be either *simple*, as when the point sought is in a right line; *plane*, as when the point sought is in the circumference of a circle; *solid*, as when the point required is in the circumference of a conic section; or *surfsolid*, as when the point is in the perimeter of a line of a higher kind, as the geometers call it.

LOCAL Trespass, in *Law*. See *TRESPASS*.

LOCANA, in *Geography*, a town of France, in the department of the Dora, on the Orco, in a valley, called the "Valley of Locana;" 21 miles S. of Aosta.

LOCARNO, one of the Italian bailliages of Switzerland, ceded to the Swiss cantons by Maximilian Sforza, duke of Milan, in the year 1512, and governed by a bailiff whose office continues two years; about 15 miles in length and about 12 in breadth. It is situated on the N.W. coast of the lake Maggiore, is fertile in grain and fruits, and contains 49 parishes, and 30,000 inhabitants. By the peace of Lunéville it was ceded to the Cisalpine republic, now the kingdom of Italy.

LOCARNO, the capital of the bailliage of the same name, a small, open, well-built, market town, agreeably situated in a fertile plain, near the N.W. border of Locarno, or Maggiore lake, and containing about 1500 inhabitants. Part of the town is built on piazzas in form of a crescent with two wings; in front is a row of trees and the public walk; the old part of the town is dirty, and the streets narrow. It contains three convents, and a small Franciscan monastery, perched on a rock overhanging the valley, and commanding a superb view of the lake and its magnificent boundaries. The canopy in the church of the Capuchins deserves mention on account of its beautiful execution; it is of straw-work, and almost rivals velvet and gold fringe. Locarno was once situated on the lake, and had a port capable of receiving large barks; at present it stands at the distance of a quarter of a mile; a circumstance which is owing to the accumulation of sand brought down by the

torrent Maggia. The environs of the town abound in wine, fruit, and pastures. It is now annexed to and included in the department of Verbano. N. lat. $45^{\circ} 59'$. E. long. $8^{\circ} 35'$.

LOCARNO, *Lake*, or *Lago Maggiore*. See LAKE.

LOCATE, a town of Italy, in the department of the Olena; 6 miles S. of Milan.

LOCATELLI, PIETRO, in *Biography*, a native of Bergamo, and one of the greatest performers on the violin in Europe, during the early part of the last century; but no less remarkable for caprice in his compositions, than for execution and a full tone in his performance. He published twelve grand concertos for violins, and much music for other instruments, at Amsterdam, where he resided from 1744 to 1764. Few could play his concertos but himself; yet there was "more method in his madness," than in that of Vivaldi; sometimes a solidity and good taste, particularly in his slow movements, not inferior to the adagios of Tartini. In 1772, we were very much surprised to find the blind organist and Canonier Potholt at Amsterdam possessed of a taste so delicate and modern in a place where little other music was encouraged or listened to than "the jingling of bells and of ducats," till that excellent performer told us that Locatelli, the famous player on the violin, who had lived many years in that city, and died in 1764, used to give him instructions, and to encourage his musical studies by allowing him the advantage of being always a hearer at his public concerts as well as private performances. This, in some measure, helped us to account for his taste and fancy; for Locatelli was possessed of a great deal of both; and though he delighted in capricious difficulties, which his hand could as easily execute as his head conceive; yet he had a fund of knowledge in the principles of harmony, that rendered such wild flights agreeable, as, in less skilful hands, would have been insupportable. Foreigners who travelled through Holland, and were curious to hear Locatelli perform, were previously apprised, that the remuneration expected was fixed at two golden ducats for himself, and a silver ducat to the person who accompanied him.

LOCATION, in the *Civil Law*, an act by which any thing is let out, on rent.

The second title of the nineteenth book of the Digest is on the subject of location and conduction. Location and conduction are relative terms, and are used as well for the action of him that lets, as for that of him who takes on that letting.

LOCATION, *Tacit*, is, when the person who takes, continues on the premises beyond the term of his lease; which by the civil law he is allowed to do, at least for the space of a year, on the same terms.

LOCCO, in *Geography*, a town of Naples, in Abruzzo Citra, on the Pescara; 10 miles N. of Sulmona.

LOCH, in the *Materia Medica*, a name given by Avicenna and others to the gum lac. They call it also *kekem* and *lenkem*, and are too apt to confound it with the cancanum, funderach, and other gums, with which they made their several sorts of varnish.

LOCH, or *Lobech*, in *Pharmacy*, a composition of a middle confidence between a syrup and a soft electuary; chiefly used for diseases of the lungs.

The word is originally Arabic; but continues still in use among the apothecaries.

The Latins call it *linctus*, and the Greeks *λεχμα*, because the manner of taking it is by licking.

LOCH, in *Geography*, a name given in Scotland to a lake and also to a bay.

LOCH Alarick, a lake in the county of Perth; 10 miles

S. of George's town:—L. *Alfarrig*, a lake in the county of Inverness; 14 miles N.W. of Fort Augustus:—L. *Ana-cat*, a lake in the county of Perth; 11 miles S.E. of George's town:—L. *Anffronmun*, a lake in the county of Perth; four miles N.W. of George's town:—L. *Aichig*, a lake in the county of Inverness, 10 miles long and one broad; 12 miles N. of Fort William:—L. *Arven*, a lake in the S.W. part of Banffshire; 21 miles S. of Inveraven:—L. *Awe*, a lake in the county of Argyle, 30 miles long, and from a mile to two wide, shaded with many small woody isles, one of which bears the ruins of a monastery, and another those of an ancient fortress, the residence of the Campbells of Lochawe, afterwards Dukes of Argyle:—L. *Baa*, a lake on the island of Mull, communicating with loch Nagaul to the N.:—L. *Barnero*, a lake or inlet of the sea, on the N.W. coast of the island of Lewis; 11 miles W. of Stornaway:—L. *Broom*, a bay on the W. coast of Scotland, seven miles long and two broad, communicating with L. *More*, its mouth being in N. lat. $57^{\circ} 36'$. W. long. $5^{\circ} 13'$:—L. *Little Broom*, a bay on the W. coast of Scotland, eight miles long and one broad; eight miles S.E. of Udrigil Head, N. lat. $57^{\circ} 52'$. W. long. $5^{\circ} 16'$:—L. *Broom*, a town of Scotland, in the county of Ross, at the S. end of L. Broom lake; 25 miles W.N.W. of Dingwall:—L. *Castle Semple*, a lake in the county of Renfrew; six miles S.W. of Paisley:—L. *Catherine*, a lake in the S.W. part of the county of Perth, about six miles in length; 20 miles W.S.W. of Crieff:—L. *Dalreoch*, a lake in the county of Ayr; 10 miles S.S.E. of Ayr:—L. *Damb*, a lake in the county of Perth; seven miles S. of George's town:—L. *Dee*, a lake in the county of Kirkcubright; 12 miles N.W. of New Galloway:—L. *Derculoch*, a lake of Perth; seven miles S. of Blair Athol:—L. *Dirantadlin*, a lake in the counties of Argyle and Perth; seven miles N.W. of George's town:—L. *Doine*, a lake of Perth; 20 miles W.S.W. of Crieff:—L. *Druinard*, a lake on the N.W. side of the island of Ilay:—L. *Drumelthy*, a lake of Perth; seven miles N.W. of Coupar:—L. *Duntelchah*, a lake in the county of Inverness; 20 miles N.E. of Fort Augustus:—L. *Eil*, a lake of Inverness, eight miles long and one broad, near Fort William:—L. *Enoch*, a lake in the county of Kirkcubright; 14 miles N.W. of New Galloway:—L. *Ericht*, a lake in the county of Inverness, 12 miles long and half a mile wide; four miles N. of George's town:—L. *Erriboll*, a capacious and safe bay on the N. coast of Scotland; three miles W. of Whitenhead, its mouth being in N. lat. $58^{\circ} 32'$. W. long. $4^{\circ} 29'$:—L. *Ersey*, a lake in Arran island; five miles N.W. of Brodick:—L. *Effan*, a lake of Perth; 18 miles S. of George's town:—L. *Etive*, a bay on the W. coast of Scotland, 20 miles long and about one broad; 15 miles N. of Inverary, N. lat. $36^{\circ} 26'$. W. long. $5^{\circ} 5'$:—L. *Fainiff*, a lake in the N.W. part of the county of Ross; 16 miles W. of Dingwall:—L. *Fine*, a bay in the county of Argyle, 34 miles long, and from one to four and six broad, extending from about six miles N.E. of Inverary to the river Clyde; its mouth being in N. lat. $55^{\circ} 50'$. W. long. $5^{\circ} 8'$:—L. *Fintarlin*, a lake in the county of Dumfries; seven miles N.W. of Lochmaben:—L. *Fitz*, a lake in the county of Fife; three miles N.N.E. of Dumfries:—L. *Frenchy*, a lake of Perth; nine miles N. of Crieff:—L. *Garry*, a lake of Perth; nine miles N.E. of George's town:—L. *Garvie*, a lake in the county of Ross; 10 miles W. of Dingwall:—L. *Gogh*, a lake which branches off to the N.W. from loch Long, N. lat. $56^{\circ} 8'$. W. long. 5° :—L. *Heck*, a lake in the county of Argyle, between loch Long and loch Fine:—L. *Inver*, a lake in the county of Kirkcubright; five miles N. of New Galloway:—L. *Kennmoor*, a lake

lake at the union of the Ken and Dee, five miles long and half a mile wide:—*L. Kingmoor*, a lake in the county of Selkirk; 11 miles S.S.W. of Selkirk:—*L. Laggan*, a lake of Inverness, eight miles long and half a mile wide; 10 miles S.E. of Fort Augustus:—*L. Laxerston*, a lake in the county of Kincardine; nine miles N.N.E. of Stonehaven:—*L. Leadmore*, a lake in the county of Ross; 24 miles W.N.W. of Dornoch:—*L. Lee*, a lake in the county of Angus; 11 miles N.N.W. of Beechin:—*L. Leven*, a bay on the E. coast of Scotland, in Inverness, 10 miles long and half a mile wide; nine miles S. of Fort William, its mouth being in N. lat. 56° 40'. W. long. 5° 20':—*Allo*, a lake of the same name, situated in the county of Kinross. Though inferior to loch Lomond, not only in extent but in beauty of scenery, still it must be allowed to present to the eye a noble expanse of water, interspersed with a variety of fruitful and pleasant islands. This lake varies in size considerably at different seasons. It is bounded on the east by the Lomond-hills, on the south by the hill of Balnearthie, and on the west by the plain of Kinross. The trout of loch Leven are of a large size, and bear a strong resemblance, both in taste and appearance, to the salmon. They are regularly brought to the Edinburgh markets, where they find a ready sale, being considered extremely delicate. The red colour of their flesh undoubtedly arises from their feeding chiefly on a small shell fish of a very deep tinge, which abounds in the bottom of the loch. A variety of other fish are likewise caught here. Eels are particularly abundant. These, in the month of September, generally migrate towards the sea in great numbers by the channel of the Leven river, which takes its rise from the lake. It is remarkable that they never proceed in their migration except during the night.

Loch Leven deserves particular attention on account of the many distinguished remains of antiquity which either adorn its islands or its banks. The ruins of the castle of loch Leven are placed upon an island nearly in the centre of the loch. Its original foundation is unknown, for though tradition says it was built by Congal, son of Dongart, king of the Picts, yet very little credit can be given to this account. The first notice taken of it in history occurs in the year 1334, when it was besieged by sir John de Sterling, an English officer, commanding a party of Scots who had joined the English army. But what principally renders this castle famous in Scottish history, is the confinement here of the unfortunate queen Mary, by the confederate lords to whom she surrendered herself prisoner, after having parted with Bothwell at Carberry. Being placed in the custody of the wife of Douglas of loch Leven, a woman of rude manners, and an inveterate enemy to the queen, she suffered all the miseries of a rigorous captivity. In this castle she remained for several months almost forgotten, till the haughty conduct of the regent having estranged the minds of many of the confederates, they resolved to rescue her and themselves from his tyranny and oppression. With this view several attempts were made to effect her release, but all of them were rendered abortive by the vigilance of her keeper. Now, however, at last prevailed over every obstacle, Mary, conscious of possessing those bewitching charms which seldom fail in securing a deep interest in the breast of ambitious youth, resolved to employ them in captivating the heart of George Douglas, her keeper's brother. She treated him with the most marked distinction, and even allowed him to enter in the night during his sleep. The temptation was too great to be resisted. Having engaged some accomplices, they contrived to secure the keys one evening, when the family were at their devotions, and opening the gates, al-

lowed the queen and her lover to escape by a boat which lay ready to receive them. As soon as they reached the shore the queen was met with the utmost joy by lord Seaton and sir James Hamilton, with whom she immediately fled to Niddrie, in East Lothian.

On another, and the largest island in the lake, the priory founded by Brudo, the last but one of the Pictish kings, formerly stood. Its ruins are still visible. Portmahomack-mo-nastery was situated on the eastern bank of the loch; only a few fragments of it remain. To the east are the ruins of the ancient tower or castle of Arnot, which was possessed by a family of that name for upwards of 600 years. For-syth's Beauties of Scotland:—*L. Lays*, a lake in the county of Kincardine; 11 miles N.W. of Stonehaven:—*L. Lochy*, a lake of Inverness, between Fort William and Fort Augustus, 10 miles long, and more than one wide, communicating with loch Eil, loch Linnhe, and loch Arneig:—*L. Lomond*, a lake in the county of Argyle, 17 miles long, and from one to four wide, with several small islands on the broadest part, which are supposed to form part of the Grampian chain, that terminates here on the W. communicating with the Clyde, by a river which joins the Clyde at Dunbarton; 24 miles W. of Stirling; its S. extremity being in N. lat. 56° 3'. W. long. 4° 30'. At the time of the earthquake in Lisbon in the year 1755, the waters of this lake were agitated in a singular manner (see LOMOND):—*L. Loyal*, a lake in the county of Sutherland, five miles long; two miles S. of Tongue:—*L. Luichart*, a lake in the county of Ross; 11 miles W. of Dingwall:—*L. Lydeoch*, a lake of Perth; five miles W. of George's town:—*L. Lyon*, a lake of Perth; 10 miles S.W. of George's town:—*L. Maudy*, a lake of Inverness; five miles long, and half a mile wide; 17 miles N.N.W. of Fort Augustus:—*L. Mabaake*, a lake of Perth; five miles N.W. of Dunblane:—*L. Montath*, a lake in the vicinity of L. Lomond, about five miles in circumference, with two woody isles, one presenting the ruins of a monastery, the other those of a castle of the old earls of Monteth:—*L. Merk*, a lake of Perth; seven miles N. of Blair Athol:—*L. Mickly*, a lake of Inverness; 13 miles N.N.E. of Fort Augustus:—*L. Milford*, or *Melfort*, a safe road or harbour, on the W. coast of Scotland, much frequented by herrings. N. lat. 56° 16'. W. long. 5° 32':—*L. Mean*, a lake in the N.W. part of the county of Kircudbright; 18 miles N.W. of New Galloway:—*L. Mocheburn*, a lake in the county of Wigton; seven miles W. of Wigton:—*L. Monar*, a lake in the county of Ross; six miles long and half a mile wide:—*L. Moarn*, a lake in the N.W. part of the county of Ross; nine miles N. of Dingwall:—*L. Moy*, a lake of Inverness, near a town of the same name; nine miles S.E. of Inverness:—*L. Naver*, a lake in the N. part of Scotland, 12 miles in circumference; 28 miles N.N.W. of Dornoch:—*L. Nall*, a lake of Argyle; 17 miles N.W. of Inverary:—*L. Ness*, a lake of Inverness; 22 miles long and one broad, between Fort Augustus and the Frith of Murray, into which its waters are discharged. This lake was affected at the time of the earthquake at Lisbon: on account of its great depth, from 60 to 135 fathoms, it never freezes:—*L. Oich*, a lake of Inverness; four miles long, and a quarter of a mile wide, communicating with loch Ness; four miles S.W. of Fort Augustus:—*L. Oochan*, a lake of Inverness; nine miles W.N.W. of George's town:—*L. Orr*, a lake in the county of Fife; six miles N.E. of Dunsinane:—*L. Orent*, a lake in the county of Caithness; six miles S. of Thurlo:—*L. Pautoch*, a lake of Inverness; 12 miles N. of George's town:—*L. Quich*, a lake of Inverness; 16 miles N. of Fort William:—*L. Rannoch*, a lake of Perth; about eight miles

miles long, E. of George's town:—*L. Rutton*, a lake in Kircudbright; four miles S.E. of Dumfries:—*L. Skin*, a lake in the N. part of the county of Sutherland; 12 miles long and $1\frac{1}{2}$ wide; 13 miles W.N.W. of Dornoch:—*L. Skene*, a lake in the county of Aberdeen; five miles S. of Kintore:—*L. Skieck*, a lake of Perth; six miles N.W. of Dunkeld:—*L. Tay*, a lake of Perth, which is a grand and beautiful expanse of water, of such length as rather to resemble a noble river, abounding with fish, and terminating in an island, on which are seen the ruins of a priory; having in its eastern extremity the capital mansion and plantations of the earl of Braidalben; 24 miles N.W. of Perth:—*L. Tollie*, a lake in Argyle; 11 miles N.N.E. of Glenorchy:—*L. Troig*, a lake of Inverness; 14 miles E. of Fort William:—*L. Tuml*, a lake of Perth; five miles S. of Blair Athol:—*L. Turret*, a lake of Perth; five miles N.N.W. of Crieff:—*L. Jack*, a lake of Perth; three miles S.S.W. of Blair Athol:—*L. Talcen*, a lake of Perth; six miles E. of Blair Athol:—*L. Tull*, a lake of Perth; 17 miles W. of Crieff:—*L. Urine*, a lake in the county of Ross; six miles long, and half a mile wide; 25 miles W.N.W. of Dingwall:—*L. Trestachan*, a lake in the S.W. part of Aberdeenshire; seven miles S. of Castleton of Braemar:—*L. Ull*, a lake of Ross; two miles W. of Dingwall:—*L. Watten*, a lake in Caithness; seven miles W. of Wick:—*L. Ythan*, a lake on the W. coast of Scotland, on the N. side of Loch Feriden.

LOCHABER, a district of Scotland, in the county of Inverness; about 40 miles long and 25 broad, of which the chief place is Fort William. This is one of the most dreary, mountainous, and barren districts in Scotland, thinly inhabited, with the houses wretched. The chief produce is black cattle, with very large flocks of sheep. Here prince Charles erected his standard in 1745, upon his landing from France, with seven officers, and arms for 2000 men.

LOCHE, or *Sea-Loche*, a name used in some parts of England for the *myxela*, called in other places, particularly in Cornwall, the *whiffle-fish*. See *GADUS MYXELA*.

LOCHEM, in *Geography*, a town of Holland, in the department of Guelderland, on the Borkel; 10 miles E. of Zutphen.

LOCHER Moss, a morass of Scotland, in the county of Dumfries; 10 miles long and three broad, which must have been formerly a forest, on account of the oak trees that are dug up in it; and as canoes and anchors have been also found here, it must have been once covered with sea.

LOCHES, a town of France, and principal place of a district, in the department of the Indre and Loire; 21 miles S.S.E. of Tours. The place contains 4342, and the canton 14,701 inhabitants, on a territory of 385 kilometres, in 18 communes. The castle, seated on a rock in this town, was formerly an important fortification. It had four ranges of subterraneous passages, running over one another, in the uppermost of which, Louis Stroz, duke of Milan, was imprisoned for 10 years, and where he died. Its large tower contains two cages or moveable rooms, with strong oak gates, covered with iron; and in one of these cardinal Balzo, bishop of Angers, was confined by Lewis XII. At a convent near the town, an edict was passed in 1576, in favour of the Protestants; but it was soon after violated by the queen regent, Catherine de Medicis. N. lat. 47° 7'. E. long. 0° 34'.

LOCHIA, in *Midwifery*, a discharge of blood from the uterus of women, occurring after the expulsion of the placenta, and continuing four, five, or more days. See *LABOUR*, *Natural*.

LOCHIAL FEVERS, a term used by medical writers

to express such fevers as arise from suppressions or diminutions of the lochial discharges in lying-in women, or from any other irregularities during the time of that discharge.

LOCHMABEN, in *Geography*, a town and royal borough, situated in the county of Dumfries, and district of Annandale, Scotland. It is supposed to have derived its name from the number of small lochs in its vicinity. This borough, according to tradition, received its original charter from king Robert Bruce, whose paternal estate was the lordship of Annandale. It is certain at least, that this monarch bestowed upon it a considerable portion of lands from his own property. The oldest charter extant is a writ of *novodamus*, by James VI., dated 16th July, 1612; which assigns as a reason for the renewal, the destruction of the town and its records by the English, during some of their inroads. Lochmaben has undoubtedly been formerly of more importance than at present. The borough-roads and town community are very extensive, and for the most part fenced off at a very trifling annual rent. The government of the town is vested in a provost, three bailies, a dean of guild, a treasurer, and nine common-council-men. Coarse linen is the staple production of this place; 60,000 yards being annually manufactured here and in the neighbourhood for the English market. The coal used for fuel is brought chiefly from Cumberland. Annan, Dumfries, Kirkcudbright, Sanquhar, and this town, join in sending one member to parliament.

The parish of Lochmaben extends about ten miles along the banks of the Annan, which possesses a very valuable salmon fishery, almost contiguous to the town. Several smaller streams flow into this river, all of which are abundantly supplied with trout. In the largest of the lochs, which present a truly beautiful sheet of water, a great variety of fish are caught. The fishermen assert, that there are 15 or 16 different kinds fit for the table. Among these is one called the vendice, or vendace, some say from Vendois in France, as being brought thence by one of the Jameses. This story, however, does not seem very probable, as it is found by experience, that this fish dies the instant it is touched. Besides, it has in vain been attempted to transport it to other lochs in the neighbourhood. The vendice is about the size of a herring, and resembles it both in external appearance and anatomical structure. In taste and flavour it is extremely delicate, so that it is reckoned among the most delicious fish that swims. It lies generally in the deepest parts of the loch, and is caught with the net.

Upon a peninsula which stretches out into this loch stands a castle, originally built by Robert de Bruce, the first of that name who swayed the Scottish sceptre. It was a place of great strength previous to the introduction of fire-arms, and could still be made so, if its fortifications were raised anew according to the principles of modern warfare. The original buildings of the castle seem to have occupied about an acre of ground. The walls were twelve feet in diameter. Three ditches surround the whole at different distances. The area contained within the outermost wall may be about 13 acres. The inner one passes through a part of the castle, within which there was a place for the security of the boats, either from the effects of the weather or an enemy. While Scotland was a distinct kingdom from England, this fort was the frontier garrison against Carlisle. The marquess of Annandale, among his other titles, assumes that of constable, or hereditary keeper of the castle of Lochmaben. To this office was attached a salary of 300*l.* Scotch, along with the fishings of the lochs. For the maintenance of the troops composing the garrison, the government had likewise what was called a *laird-a-mart*, or *lairdiner mart*.

mart cow, which was one of the best fat cows from every parish in Annandale. Very little of the cattle now remains, it having been completely pillaged of its materials for the construction and ornament of many of the houses in the neighbourhood.

Between this castle and the Kirk-lochs, close to the town, are the vestiges of another fort of more ancient date. Tradition reports that the stones were removed to assist in building another castle, probably that in the loch. The situation of this castle is fine, and commands a beautiful prospect over an extensive plain. It was originally the residence of the Bruce family, before they ascended the throne of Scotland. It is said that king Robert I. was born here.

Contiguous to the castle first mentioned, on the banks of the Annan, lies a large tract of fertile land, called the Four-towns, as comprehending four populous villages. These lands were originally granted by one of the Scottish monarchs to his household servants, and the property of each being very small, bare possession was declared a sufficient title. When any part of this property is transferred, it is only necessary to mark the transaction in the books of the lord of the barony. In measuring the lands of this district, an ell, called the barony ell, is made use of, which contains 42 inches, whereas the common ell of the country is only 38 inches.

Lochmaben and its vicinity derive no small degree of celebrity, as the scene of some of the heroic actions of the renowned sir William Wallace. According to the population report of 1801, this parish contained 499 houses, and 2053 inhabitants.

LOCHNEV, a town of Sweden, in the province of Smaland; 60 miles N. of Calmar.

LOCHSTETT, a town of Prussia, in the province of Smaland, near which are the ruins of a castle, in which was a dungeon, that served for a prison; four miles N. of Pillau.

LOCHVITZE, a town of Russia, in the government of Tchernigov, on the Sufa; 96 miles S.E. of Tchernigov. N. lat. 50° 20'. E. long. 28° 14'.

LOCIS COMMUNIBUS. See COMMUNIBUS.

LOCK, MATTHEW, in *Biography*, organist and composer to his majesty Charles II.; was a native of Exeter, and a chorister in the cathedral of that city, while William Wake was organist there. He had afterwards instructions in music from Edward Gibbons, and had so much distinguished himself as a professor of abilities, that we are told in the continuation of sir Richard Baker's chronicle, he was appointed to compose the music for the public entry of the king at the restoration, and captain Henry Cook for his coronation.

But he seems first to have appeared as an author in 1657, during the interregnum, by the publication of his "little consort of three parts for viols or violins, consisting of ravans, ayres, corants, farabands, in two several varieties, the first twenty of which are for two trebles and a base."

Some of his compositions appear in the second part of John Playford's continuation of Hilton's "Catch that catch can," in 1667. Of which publication, the second part contains "Dialogues, Glee, Ayres, and Ballads, of two, three, and four voices," among which we find the most pleasing of Lock's compositions; "Never trouble thyself about times or their turnings," a glee for three voices.

Lock was the first who attempted dramatic music for the English stage, if we except the masques that were performed at court, and at the houses of the nobility, in the time of Charles I., and during the reign of Charles II. When musical dramas were first attempted, which Dryden calls heroic

plays and dramatic operas, Lock was employed to set most of them; "Circe," written by sir William Davenant's son, Dr. Davenant, was set by Bannister; but the *semi-operas*, as they were called, the *Tempest*, *Macbeth*, and *Psyche*, translated from the French of Moliere by Shadwell, were set to music by Lock. The *Tempest* and *Psyche* were performed in 1673, with music, dancing, and splendid scenes, but not printed till 1675, when it was published with the following title: "The English Opera; or the vocal Music in *Psyche*, with the instrumental therein intermixed. To which is added the instrumental Music in the *Tempest*. By Matthew Lock, composer in ordinary to his Majesty, and Organist to the Queen." This publication is dedicated to James duke of Monmouth. There is a preface of some length by the composer, Matthew Lock, which, like his music, is rough and nervous, exactly corresponding with the idea which is generated of his private character, by the perusal of his controversy with Salmon, and the sight of his picture in the music-school at Oxford. It is written with that natural petulance which probably gave birth to most of the quarrels in which he was involved. He begins with a complaint of the tendency of his brother musicians "to peck and carp at other men's conceptions, low mean favour may be their own. And expecting to fall under the lash of some soft-headed or hard-hearted composer," he sets about removing "the few blocks at which they may take occasion to stumble," with a degree of indignation that implies an irascible spirit under no great governance. The first objection which he thinks likely to be made, is to the word opera, to which he answers, that it is a word borrowed from the Italian, who by it distinguished this kind of drama from their comedies, which, after a plan is laid, is spoken extempore; whereas this is not only designed, but written with art and industry; and afterwards set to suitable music. In which idea he has produced the following compositions, which, for the most part, are "in their nature soft, easy, and, as far as his abilities could reach, agreeable to the design of the poet. For in them there is ballad to single air, counterpoint, recitative, fugue, canon, and chromatic music, which variety, without vanity be it said, was never in court or theatre, till now presented, in this nation." He confesses, however, that something had been attempted before in this way of composition, but more by himself than any other. And adds, "that the author of the drama prudently considering, that though Italy was and is the great academy of the world for music and this species of entertainment, yet as this piece was to be performed in England, which is entitled to no such praise, he mixed it with interlocutor, as more proper to our genius."

He concludes his peevish preface by confessing, that "the instrumental music before and between the acts, and the entries in the acts of *Psyche*, were omitted by the consent of the author, Signor Gio. Baptista Draghi; and that the tunes of the entries and dances in the *Tempest* (the dances being changed) were omitted for the same reason."

Here we have a short history of these early attempts at dramatic music on our stage, in which, as in the most successful representations of this kind in later times, the chief part of the dialogue was spoken, and recitative, or musical declamation, which seems to be the true criterion and characteristic of Italian operas, but seldom used, unless merely to introduce some particular airs and choruses: as in the modern *Comus*, the air, "On ev'ry hill, in ev'ry dale," is preceded by the short recitative "How gentle was my Damon's air."

Upon examining this music, it appears to have been very much composed on Lulli's model. The melody is neither recitative

recitative nor air, but partaking of both, with a change of measure as frequent as in any old French opera which we ever saw.

Lock had genius and abilities in harmony sufficient to have surpassed his model, or to have cast his movements in a mould of his own making; but such was the passion of Charles II. and consequently of his court at this time, for every thing French, that in all probability Lock was instructed to imitate Cambert and Lulli. His music for the witches in Macbeth, which, when produced in 1674, was as smooth and airy as any of the time, has now obtained, by age, that wild and savage cast which is admirably suited to the infernal characters that are supposed to perform it.

In the third introductory music to the Tempest, which is called a *curtain tune*, probably from the curtain being first drawn up during the performance of this species of overture, he has, for the first time that is come to our knowledge, introduced the use of *crescendo* (louder by degrees,) with *diminuendo*, and *lento*, under the words *soft* and *slow by degrees*. No other instruments are mentioned in the score of his opera of *Psyche*, than *violins* for the ritornels; and yet, so slow was the progress of that instrument during the last century, that in a general catalogue of music in 1701, scarce any compositions appear to have been printed for its use.

This musician was of so irascible a disposition, that he seems never to have been without a quarrel or two on his hands. For his furious attack on Salmon, for proposing to reduce all the clefs in music to one, (see SALMON and CLEF,) he had a quarrel with the gentlemen of the Chapel Royal, early in Charles II.'s reign. Being composer in ordinary to the king, he produced for the Chapel Royal a morning service, in which he set the prayer after each of the ten commandments, to different music from that to which the singers had been long accustomed, which was deemed an unpardonable innovation, and on the first day of April 1666, at the performance of it before the king, there was a disturbance and an obstruction for some time to the performance. To convince the public that it was not from the meaness or inaccuracy of the composition, that this impediment to its performance happened, Lock thought it necessary to print the whole service; and it came abroad, in score, on a single sheet, with a long and laboured vindication, by way of preface, under the following title; "Modern church-musick pre-accused, censured and obstructed in its performance before his majesty."

Lock was long suspected of being a Roman Catholic, and it is probable that this new service, by leaning a little more towards the mass, than the service of the Protestant cathedral, may have given offence to some zealous members of the church of England.

The public were indebted to Lock for the first rules that were ever published in England, for a *basso continuo*, or *thorough-bass*; these rules he gave to the world, in a book entitled "Melothesia," London, oblong 4to. 1673. It is dedicated to Roger l'Estrange, esq. afterwards sir Roger l'Estrange, an ingenious man, a good musician, and an encourager of its professors. It contains, besides the thorough-bass rules, some lessons for the harpsichord and organ by Lock himself, and others. He was author likewise of several songs printed in "The Treasury of Music," "The Theatre of Music," and other collections of songs. In the latter of these is a dialogue. "When death shall part us from these kids," which, with Dr. Blow's "Go, perjured man," was ranked among the best vocal compositions of the time.

It is presumed, that when he was appointed composer in ordinary to the king, he was professionally a member of the church of England; but it is certain that he went over to

the Romish communion afterwards, and became organist to queen Catherine of Portugal, the consort of Charles II. and died a Papist in 1677.

Lock, a well-known instrument for securing doors and preventing them from being opened, except by means of the key adapted to it. A common lock consists of a strong bolt, which must be fitted in a proper box or case affixed to the door, and inclosing it on all sides, to defend it from violence, that it cannot be withdrawn, except by the application of the key, which should enter the lock by a small key-hole, and be surrounded by numerous wards, that occasion the passage the key passes through, in turning round to move the bolt, to be very crooked and intricate, and thus preventing the introduction of any instrument or false key to withdraw the bolt. The third part of the lock is the tumbler, which is a catch or click holding the bolt from being withdrawn, except the tumbler is first removed by the key, which is done at the same time it shoots the bolt. This common lock cannot be made perfectly secure from being picked or opened without the right key, from the circumstance that the wards, though they may be variously disposed, so as to require a very crooked key, must be always left fixed in the lock, and their figure may be taken by introducing a small false key, covered with wax or other plastic substance, and receiving the impression of the wards, from which information a false or skeleton key may be made, that will enter the lock and withdraw the bolt; or, if it will only raise up the tumbler, the bolt may sometimes be forced back by other means. Another reason of the insufficiency of the common lock is, that the variations capable of being made in the arrangement of the wards are not sufficient to produce the required number of locks without having great numbers exactly alike, and their keys capable of opening each other reciprocally; from which circumstance they become but an imperfect security, as any ill-disposed person may, by furnishing himself with a great variety of old keys, be enabled to open almost any common lock; particularly if these keys are filed away to skeletons, that is, leaving as little as possible of the solid part of the key, which will then have a greater chance of passing in between the intricate wards.

To produce a lock which would be free from these objections has been the study of many ingenious mechanics, whose various locks have different properties and advantages. We have devoted *Plate XXI. Miscellany*, to the explanation of two capital locks, one by Mr. Thomas Rowntree, which is an improvement upon the common tumbler-lock, and another by Mr. Joseph Bramah, which is on an entirely different principle.

Mr. Rowntree's lock is represented in *figs. 5, 6, 7, and 8*; in these the following parts are those of the common lock: A A is the plate which incloses the whole mechanism, and fastens it to the door; B B, *fig. 6*, is the bolt, which is guided in its motion by sliding under two bridges C, D, screwed to the main plate; E, E, are four pillars which support a plate to cover the works: this plate has the key-hole in it; F, &c. are the circular wards surrounding the centre pin; and a, *fig. 6*, is the key which, in turning round, acts in a notch *r* in the bolt, and shoots it forwards or backwards; G is the tumbler: it is a plate situated beneath the bolt and moving on a centre pin at *d*. See also *fig. 8*, which is a separate view of the tumbler; it has a catch *e* projecting upwards from it, which enters the notches *f* or *g*, *fig. 6*, in the bolt, and thus firmly retains the bolt; the former when it is locked, and the latter when it is drawn back. H is a spring which presses the tumbler forwards; the key *a*, in turning round, acts first against the part *c* of the tumbler, and raises

raises it so as to remove the catch *c* from the notches *f* or *g*, and then the key enters the notch *r* in the bolt, and moves it. In this, which is the common lock, it will be seen there is no security, except what arises from the intricacy of the wards *F* surrounding the key; for a false key, or any other instrument which is of the same length as *a*, will, if it can pass the wards, raise the tumbler and draw back the bolt. Mr. Rowntree has, by applying an ingenious contrivance to this lock, rendered it so secure, that it will be nearly impossible to pick or open it with any other than the true key. To the tumbler he has added a piece of metal *b*, *figs.* 7 and 8, called its *fin*, fixed to its lower side. When the tumbler is locked in the notches *f*, *g*, of the bolt, the fin applies itself to a cluster of small wheels *I*, *figs.* 5 and 8, all fitted on one centre pin beneath the tumbler: the edges of these wheels stop the fin *b*, and prevent the tumbler being raised; but each wheel has a notch *i*, *fig.* 8, cut in its circumference, and when they are all placed, so that every notch is turned to the side opposite the fin of the tumbler, and forming one notch through the whole cluster of wheels, then the fin is at liberty to enter this notch, allowing the tumbler to rise: but when the tumbler is down, and the plain edges of all or any of the wheels are presented to the fin, the tumbler cannot be raised unless the wheels are first put into the right position above-mentioned: this is done by a number of levers *K*, *figs.* 5 and 7, all centred on one pin at *k*. At the opposite end each has a tooth *m*, entering a notch in the wheel belonging to it, so that when any lever is pressed outwards it turns its wheel round. The levers are pressed towards the key by a spring *n* applied to each, and in this state they rest against a pin *o* fixed in the plate. The wheels are now disarranged completely, every one presenting its plain edge to the fin, but every one requiring a different degree of motion to bring the notch round to the proper position. When the key is introduced and turned round, it first operates upon the curved part *p*, *q*, *fig.* 5, of the levers *K*, and raising them, turns all the circles *I* at once into the proper position. The key, in turning farther round, operates on the part *e*, *fig.* 6, of the tumbler, now at liberty to move, and by raising it releases the bolt, and in turning still further round, it raises the notch *r* of the bolt, as in *fig.* 6, and shoots it. The key is cut into steps of different lengths, as shewn at *v*, *u*, in *fig.* 1: each step operates on its respective lever *K* in a different degree, and turns its circle *I* the proper quantity. The notch at *s* acts upon the tumbler, and the plain part *t* moves the bolt. In this lock there is no possibility of picking it, for if all the levers except one were raised the proper quantity, that one would detain the tumbler as effectually as the whole number; and a false key, besides having the wards as *R*, must have all the notches *v*, *u*, of the exact depth, neither greater nor less, or it will not open the lock, even if one alone is incorrect. If the key is lost, when a new one is made, the maker takes out the levers *K* and circles *I*, and arranging them in a new order, one upon the other, making the new key to fit the new arrangement, and then the old key will not open the lock; though none of the parts are altered, but only their arrangement. The same may be done if it be suspected that an impression has been fraudently taken from the key to make a false one by.

The locks invented by Mr. Joseph Bramah display great ingenuity, and demand a particular description, having been in very general use for many years past, and greatly admired. He obtained a patent for his invention in 1784, and established a manufactory of them, in which he employed a number of ingenious tools and engines for the fabrication of the different parts. One of Mr. Bramah's simplest forms of a lock for a drawer, or for a door, is represented in *figs.* 1, 2, 3, 4. *Plate*

XXII. *Miscellany*, in which *A* represents the bolt, fitted to slide on the metal plate *BBC*, by passing through a hole in the side *C*, which is turned up, as shewn in *fig.* 3: the other end of the bolt is guided by passing under proper grooves in the lower side of the circular box *DD*, which is screwed to the plate *B* to confine the bolt down. It contains the whole mechanism of the lock, consisting of an interior cylinder or barrel *EE*, shewn in the section *fig.* 3, with its appendages in perspective in *fig.* 4. This barrel is fitted to turn round within the box *DD*, the upper end *aa* being received into a cavity exactly fitting it, and the middle encompassed by a circular ring of steel plate *bb*, screwed into the box as shewn in *fig.* 3, and one-half shewn at *b*, *fig.* 4. The ring enters a circular groove formed round the barrel, and thus confines it from having any other motion than a rotation on its axis, and this only by the aid of the key *R*, as will be explained. The barrel has a hole through its centre, which is closed at bottom by a circular plate *F*, screwed to it, and supporting the central pin *G*, which occupies the centre of the hole through the barrel: this centre pin guides the key in entering the lock. When the barrel *EE* is turned round by the key, it shoots the bolt *A*, by an ingenious contrivance, explained in *fig.* 2, an aperture being cut through the plate *BBC* to exhibit it. The plate *F*, on the lower end of the barrel *E*, has a pin *f* projecting from it: this pin enters a curved opening, at a small distance from the centre, and therefore describes a circle when the barrel is turned round, cut through the bolt *A*, as is shewn by the dark curve *F* in *fig.* 2. In the position there shewn the bolt is withdrawn, and the pin *f*, resting against the solid part of the groove, prevents the barrel being turned round any farther in the direction from *F* to *f*: but by the application of the key, the barrel may be turned in the other direction from *f* to *F*, in which course it passes round in a circular part of the groove, and therefore produces no motion of the bolt *A*, until the pin *f* strikes the straight part *g* of the groove, and acts against it to throw the bolt forwards: and when the barrel has made a complete circuit, and the pin *f* is again come to the same position it was at first, the bolt is shot out as at *fig.* 1, and the pin is resting in the hollow *h*, which prevents it moving any farther in the same direction. When the barrel is turned back again, the pin *f* acts against the notch *i* and the curved part *k* of the groove, and withdraws the bolt into the position of *fig.* 2: now the pin *f*, either when the bolt is shot out or in, is in a right line with the centre of the barrel *E*, to which it is fixed, and the direction of the bolt's motion. By this means, no force whatever applied to drive back the bolt can have the least tendency to turn the barrel round, and strain the mechanism which prevents its motion, unless the parts are first put into a particular arrangement, by the application of the key. The interior mechanism must be explained by *fig.* 4, in which *l*, *m*, *n*, represent small steel sliders, which are fitted into proper grooves or flits, made in the substance of the barrel *E*. Of these there are six in number, arranged round the barrel, and projecting a little from its exterior surface in the small part. These sliders are received in notches *y*, *z*, in the fixed steel ring *bb*, before described; and thus effectually detain the barrel at six points from being turned round, except it is first unlocked by the key *R* being introduced at the key-hole *H*, and the sliders pressed down by it, so as to bring the notches (of which each slider has one, as at *r* *fig.* 4) all opposite the steel plate *bb*, and then the barrel may be turned round. When the key is absent, the sliders are raised up by a brass ring *v* sliding on the central pin *G*, and lifted up by a spiral spring *w*. The key has six notches cut in the end of it, as shewn at *S*, which is an end view: each notch in the key includes one of the six sliders *l*, *m*, *n*, and

and the key, being forced down into the key-hole H, depresses all the sliders at once, until the projecting leaf *t* of the key stops upon the bottom of the recess *x*, cut in the upper edge of the barrel. In this position the sliders are depressed, so that the notch *r* made in each slider comes exactly opposite the steel ring *b b*, and the barrel is at liberty to turn round all the sliders, being by this means removed, or at least relieved, from the steel ring, which, as before mentioned, embraces a groove cut round the barrel, but which cannot turn round therein unless the sliders are also moved by the key, that the notches cut in them coincide with the groove cut round the barrel, and then it can turn freely round. The key, having thus relieved the barrel by being thrust in as far as it can go, obtains a hold of the barrel to turn it round, by the leaf *t* entering the recess *x*, which it exactly fills up, so as to form a continuation of the circular top of the barrel: but as soon as the key is turned round with the barrel a small quantity, its leaf is caught beneath the circular cavity in the top of the box D, and thus the key is prevented from being thrown out by the spiral spring *w*, until it has been turned quite round, and locked or unlocked the bolt: then the leaf of the key coming opposite the enlargement *z*, *fig. 1*, of the key-hole H, the spring throws the key out and raises all the sliders, that they may interlock with the steel plate *b b*, and prevent the barrel from turning, unless the key is again put in, (its leaf being opposite the aperture *z* of the key-hole,) and being thrust forwards as far as it will go, the barrel will turn round very easily; and when it has made a complete circuit, the lock is opened, and the key thrown out of the key-hole by the spring.

The security of this ingenious lock from being picked, or opened by a false key, depends upon a circumstance not yet mentioned, which is, that the notches in the six sliders are so made, that every one requires to be depressed a different quantity to bring them all at once opposite the steel ring, in which position alone the barrel can be moved. For this reason the six notches in the key are all of different depths, correspondent to the positions of the notches in their respective sliders; and unless each notch in the key is of the proper depth, the lock cannot be opened, for any one being too deep, that slider will not be pressed low enough to relieve the barrel, and will hold it fast, though all the others may be correct: on the other hand, any notch not being of sufficient depth, the slider it acts upon will be pressed too far, and in this case the notch in it, having passed by the steel ring, will lock the barrel as effectually as though it was not far enough. Thus this lock admits of an immense number of combinations: 1st, in the number of the sliders; 2^{dly}, the depths of the different notches in the key; and 3^{dly}, the arrangement of these sliders. The combination of these three changes admits such an immense number of varieties of locks, that it never need happen that two locks should be made to open by the same key. Any of Mr. Bramah's locks may be arranged so as to require a new and different key in case the original should be lost or stolen: for this purpose the lock must be opened, and the sliders taken out and changed into different grooves: a new key must now be made, with the grooves of the same depth of the original key, but arranged in a different order, corresponding with the new arrangement of the sliders. The old key will not now open the lock.

To pick a lock of this kind is perhaps impossible; because, though the sliders are exposed to the examination of any person, yet no information can be obtained of the depth of each of the sliders required to be depressed; for, unless they are all together pressed down, the barrel cannot be turned in the least, and without turning it, no guess can be made

by pressing down any one slider of the depth at which the notch in it will be opposite the steel ring. Another great advantage of these locks is, that from the circumstance before explained, of the bolt having no action to turn the barrel, though the barrel has a great power to shoot the bolt, a strong lock may have but a very small key. For instance, the bolt of the lock, in the plate which is drawn its full size, is of great strength, while the key R is so small, that it may always be carried suspended to the watch chain, and then it will not be in danger of being lost or mislaid, as one may happen to lose a key, and give opportunity for ill disposed persons to make a false key from it, unknown to the owner.

A lock invented by Mr. Stanbury, an American gentleman, has great merit. To explain it, we must suppose that a flat circular plate is fitted to turn round upon the centre pin for the key, and that this plate, when turned round, shoots the bolt, which may be done by various means. The locking part consists of four, six, or more small steel pins, which are received in holes made very near each other, through both the circular turning plate, and the fixed plate beneath it. By these pins the circular plate is held fast from turning. The key has the same number of pins, and arranged in the same position and distance as the pins in the plate. The key being introduced, it is pressed forwards against the circular plate, and turned round till the pins in it come over the pins in the circular plate, and the pressure of the hand forces the pins out of the circular plate, the pins in the key occupying the place of them. The plate is now relieved, and the key has hold of the plate to turn it round and open the lock. Each pin is provided with a spring behind the fixed plate to force it forwards. The difficulty of making a false key to this lock is very great; as any error in the number, size, position, or length of the pins, will prevent it from opening the lock. To avoid the danger of impressions being taken, many marks are stamped upon the circular plate, which are exactly the same as the marks of the real pins: thus an impression taken from it would only mislead.

Mr. Stanbury has also made an ingenious improvement upon the common spring door-lock. The handle which opens the spring catch for fastening the door, instead of requiring to be turned round, is made so that it withdraws the spring catch, by pushing the handle on one side of the door and pulling it on the other. This method is extremely convenient; for pressing the handle releases the lock, and continuing the pressure opens the door, and pulling the handle on the other side has the same effect. A person with his hands full may open such a door by only leaning against the handle.

Lock, or *Weir*, in *Inland Navigation*, the general name for all those works of wood and stone, made to confine and raise the water of a river: the banks also which are made to divert the course of the river, are called by these names in some places. But the term *lock*, or *pond-lock*, is more particularly appropriated to express a contrivance, consisting of two gates, or pairs of gates, called the lock-gates, and a chamber between, in which the water may be made to coincide with the upper or lower canal, according as the upper or lower gates communicating with it are opened; by which means boats are raised or depressed from one level or reach of a canal to another. See *Plate V. Canals*.

Lock of Water, is the measure equal to the content of the chamber of the locks, by which the consumption of water on a canal is estimated.

Lock-keeper, a person who attends the locks to take

care of them, and to assist the boatmen in passing through them.

Lock-paddles are the small sluices that serve to fill and empty the locks.

Lock-fills are the angular pieces of timber, (*b, b*, *Plate V. Canals, fig. 36.*) at the bottom of the lock, against which the gates shut.

* *Lock-rollers*, or *Paddle-rollers*, are the over-falls behind the upper gates, (*a, a*, *Plate V. fig. 37.*) by which the water of the upper pound is let down through the paddle-holes into the chamber of the lock.

To *Lock*, in *Fencing*, is to seize your adversary's sword-arm, by twining your left arm round it, after you close your parade, shell to shell, in order to disarm him.

LOCKARTSBURG, in *Geography*, a town of America, in Luzerne county, Pennsylvania, situated on an isthmus, formed by the confluence of the Susquehanna and Tioga rivers, about a mile above their junction.

LOCKE, JOHN, in *Biography*, one of the greatest philosophers and most powerful writers that ever adorned this country, was born at Wrington, in Somersetshire, on the 29th of August 1632. His father was a gentleman of strict probity and economy, and he possessed a handsome fortune. He took great pains in the education of his son; and, when he was of a proper age, sent him to Westminster school, where he continued till the year 1651, when he was entered a student of Christ-church college, in the university of Oxford. Here he was distinguished above all his contemporaries, and was considered to be the most ingenious young man in the college. It appears, however, that he was disgusted with the method of study prescribed to him, which was after the manner of the Peripatetics; and it is said, that the books which first gave him a relish for the study of philosophy were those written by Des Cartes. Having taken his degrees in arts in 1655 and 1658, Mr. Locke for some time closely applied himself to the study of physic; and it is certain that, for a short time, he followed it as a profession. In the year 1664 he accepted an offer to go abroad, as secretary to sir William Swan, envoy from Charles II. to the elector of Brandenburg; but returning to England again within less than a year, he resumed his studies at Oxford with renewed vigour, applying himself particularly to natural philosophy. In 1666 he was accidentally introduced to the acquaintance of lord Ashley, afterwards earl of Shaftesbury, in the capacity of a medical practitioner, during the absence of the physician who regularly attended his lordship. When the noble lord left Oxford to go to Sunning Hill, he made Mr. Locke promise him a visit there, which promise he performed in 1667. Having secured him as an inmate, lord Ashley suffered himself to be governed entirely by his advice, and became so much attached to him, that he would not suffer him to practise medicine out of his own family, except in the case of some particular friends; and perceiving that the great abilities of Mr. Locke were calculated to render him eminently serviceable to the world in other departments of knowledge, urged him to apply his talents to state affairs and political subjects. To these Mr. Locke was naturally inclined, and succeeded so well, that lord Ashley began to consult him on all occasions. He was now introduced to the society of some of the most eminent men of letters, who were all delighted with his conversation. In the year 1668, Mr. Locke accompanied the earl and countess of Northumberland in a tour to France, and returned in the same way with the lady, while his lordship set off to Italy, with an intention of visiting Rome. This nobleman, however, died on his journey, and Mr. Locke accompanied the countess to England, and again took up

his residence at lord Ashley's. His lordship, at that period chancellor of the exchequer, having, in conjunction with other noble lords, obtained a grant of Carolina in North America, employed Mr. Locke to draw up a constitution for that province. In executing this task, he had formed articles relative to religion and public worship on those enlarged principles of toleration, which were agreeable to his own enlightened views upon that subject. The clergy, however, jealous of a diminution of their powers, caused an additional clause to be inserted, securing the countenance and support of the state only to the exercise of religion according to the discipline of the established church. Mr. Locke, notwithstanding his connection with lord Ashley, made frequent visits to Oxford, though he was at the same time engaged to inspect the education of his lordship's eldest son, an office which he executed with the greatest care, and to the entire satisfaction of his employer. To Mr. Locke, likewise, was confided the important charge of selecting a wife for the young man. This was a task of great difficulty, as the father determined he should only marry a lady of good family, of an agreeable temper, a fine person, and, above all, of good education and excellent understanding. Notwithstanding the difficulties attending such a commission, Mr. Locke undertook it, and executed it to the perfect satisfaction of all parties. The eldest son by this marriage, afterwards the author of the "Characteristics," was committed to the care of Mr. Locke in his education, and gave evidence to the world of the master-hand which had directed and guided his genius. In 1670 Mr. Locke began to form the plan of his "Essay on Human Understanding;" but he was too much engaged by his patron to make much progress in the work. In 1672, lord Ashley was created earl of Shaftesbury, and appointed to the high dignity of lord high chancellor of England. His lordship immediately made him his secretary of the presentations; but he held that place only till the end of the following year, when the earl was obliged to resign the great seal. After this, lord Shaftesbury was president of the board of trade, and Mr. Locke was appointed secretary to the same. The commission being dissolved in 1674, he was again at leisure, was admitted to the degree of bachelor of physic, and began to turn his attention to that faculty, as the means of future support. He was at this time in the highest estimation with several persons of eminence in the medical profession: Dr. Sydenham, among other, speaking of him, says, "If we consider his genius, and penetrating and exact judgment, or the strictness of his morals, he has scarcely any superior, and few equals now living." In 1675, Mr. Locke sought relief from a pulmonary complaint by travelling to the south of France, where he became acquainted with the earl of Pembroke, to whom he communicated his plan of writing the "Essay on Human Understanding." He afterwards settled at Paris, where he obtained the friendship of several men of letters. In 1679 the earl of Shaftesbury, being restored to favour at court, and made president of the council, sent to request that Mr. Locke would return home without delay. He instantly complied; but within six months that nobleman was again displaced, for refusing his concurrence with the designs of the court, which aimed at the establishment of popery and arbitrary power; and in 1682, he found it necessary to retire to the continent, to avoid a prosecution for high treason, on account of offences charged upon him, probably without the colour of reason or truth. Mr. Locke, whose character was above all suspicion, remained steadily attached to his patron, following him into Holland; and upon his lordship's death, which happened soon afterwards, he did not think it safe to return to his native

native country, where his intimate connection with lord Shaftesbury had created him some powerful and malignant enemies. Their malice pursued him to the utmost extent of their means; and the dean of Christ-church had orders from the king to eject Mr. Locke from his student's place, which was accordingly done. On the accession of James II., William Penn, the quaker, who was the friend of Locke in his adversity, used his interest with the king to procure a pardon for him: and would have obtained it, had not Mr. Locke declined the acceptance of such an offer, declaring that he had no occasion for a pardon, having never been guilty of any crime. In 1685, when the duke of Monmouth and his party were making preparations in Holland for his rash and unfortunate enterprize, the English envoy at the Hague demanded that Mr. Locke, among others, should be given up, on suspicion of his being actively engaged in the undertaking. This suspicion, though entirely groundless, obliged him to lie concealed nearly a year; till it was rendered perfectly evident, even to his enemies and their spies, that he had no concern whatever in the business. Towards the end of the year 1686 he appeared again in public, and soon afterwards was the principal agent in forming a literary society at Amsterdam, of which Limborch, Le Clerc, and other learned men were members, who met together weekly for conversation upon subjects of universal learning. In the following year he finished his great work, the "Essay concerning Human Understanding," which had been the principal object of his attention several years, and which proves how well he spent the period of his exile from England. That the public might be apprized of the outlines of his plan, he himself made an abridgment of it, which his friend Le Clerc translated into French, and inserted in one of his "Bibliothèques." This abridgment was so highly approved by the literati of that period, and by those who were sincerely attached to truth and just principles, that they took every opportunity of expressing the strongest desire to see the complete work in its original state. During his concealment, he wrote his "Letter concerning Toleration," which was first published in the Latin language at Gouda, in 1689, and entitled "Epistola de Tolerantia ad clarissimum Virum T. A. R. P. T. O. L. A. Scripserat P. A. P. O. J. L. A." The former of these sets of letters were intended to signify Theologie apud Remonstrantes Professorem, Tyrannidis Oforem Limburgium Amstelodamensem; and the latter, Pacis Amico, Persecutionis Ofore, Johanne Locke, Anglo. This letter he afterwards translated into English, and published in London in the year 1690. It was speedily translated into the Dutch and French languages, and has been exceedingly popular with liberal people of all countries from that period to the present. It has been frequently reprinted in forms adapted for general circulation, and has been distributed by persons of fortune and rank, among whom may be mentioned, in our own country, his grace the late duke of Grafton. This epistle, though so highly approved, was severely attacked by a clergyman of Oxford, who wrote three pamphlets against it; two of which Mr. Locke answered, defending and justifying his principles with invincible strength of argument: and though he was in a declining state of health, when his antagonist, after twelve years' silence, published his third pamphlet against it, yet he began a reply to him in a "Fourth Letter concerning Toleration." Though this was not finished, yet the fragment has been published in Desmaizeaux's edition of his works.

To return, however, to the narrative of Mr. Locke's life, in the order of time. The revolution of 1688 opened a way for his return into his own country, whither he came

in the same fleet which conveyed the prince of Orange; and upon the restoration of public liberty, he did not hesitate to assert his own private rights, and accordingly put in his claim to the student's place in the college of Christ's-church, of which he had been unjustly deprived. For the sake of peace, he was advised to desist from his claim. As he was considered to be a sufferer for the principles of the revolution, he might have obtained some very considerable post under government: but he contented himself with that of "Commissioner of Appeals," worth about 200*l.* *per annum*. In the year 1689, Mr. Locke had an offer to go abroad in a public character; but he declined the honour and advantages attached to such a situation, on account of the infirm state of his health: and in the following year he published his "Essay," which has given him an immortal reputation; and which, at the time, though it had many enemies, was styled "one of the noblest, most useful, and most original books the world ever saw." Those who disliked every thing like innovation, opposed the progress of our philosopher's principles as laid down in his "Essay." It was even proposed, at a meeting of the heads of the houses of the university of Oxford, to censure and discourage the reading of it; and after long and warm debates among themselves, it was agreed that each individual, at the head of a college, should endeavour to prevent it from being read by the students: a sure method of rendering every spirited young man anxious to peruse it, and even imbibing its principles. The old and the prejudiced were afraid of the light which was diffusing itself in the world, but they could not restrain its effects: the attacks of Mr. Locke's various opponents did but increase his reputation, and render his principles more generally studied and adopted. Mr. Locke's next publication was his "Two Treatises on Government;" in which he vindicated the principles upon which "the Revolution" was founded, and completely demolished sir Robert Filmer's false principles; pointing out, at the same time, the true origin, extent, and end of civil government. About this period, the public coin of the kingdom was known to be in a very bad and depreciated state, having, by being clipped and sweated, lost one-third of its weight. The magnitude of this evil, and the mischief which it threatened, called for the attention of parliament; and Mr. Locke, with the view of assisting those who were at the head of affairs to form a right understanding of this matter, and to excite them to rectify such abuses, printed a tract, entitled "Some Considerations of the Consequences of lowering the Interest, and raising the Value of Money." He had warned the public of their danger, and said, "the nation was in greater danger from a secret unobserved abuse, than from all those other evils of which persons were generally so apprehensive; and that if care was not taken to rectify the coin, that irregularity alone would prove fatal to us, though we should succeed in every thing else." Mr. Locke published other tracts on the same subject, by which he convinced the world that he was as able to reason on trade and business as on the most abstract questions of science. He was accordingly consulted by the ministry relative to a new coinage of silver. With the earl of Pembroke, then lord keeper of the privy seal, he was accustomed to hold weekly conferences; and he was in habits of intimacy and friendship with the earl of Peterborough, at whose house, at Fulham, he always met with a hospitable and kind reception, when the delicacy of his health obliged him to quit the metropolis. He was afterwards obliged to leave London entirely, and accepted of the generous offer of sir Francis Masham, at Oates in Essex, to become a resident in his house, where he spent the remainder of his life. Here he

was received on his own terms, that he might have his entire liberty, and look upon himself as at his own home; and here he chiefly pursued his future studies, being seldom absent, because the air of London grew more and more troublesome to him. In 1693 he published his "Thoughts on Education," which he improved in some subsequent editions; and in 1695 he was appointed, by the king, one of the "Commissioners of Trade and Plantations," which obliged him to be more frequently in London than he had been for some time past. In the same year he published his excellent treatise, entitled "The Reasonableness of Christianity as delivered in the Scriptures;" of which he afterwards published a vindication, in answer to a scurrilous attack by Dr. Edwards, entitled "Socinianism unmasked." Scarcely was Mr. Locke disengaged from this controversy, before he was drawn into another, occasioned by the publication of Mr. Toland's "Christianity not mysterious," in which he endeavoured to prove "that there is nothing in the Christian religion not only contrary to reason, but even nothing above it;" and in explaining his notions, he made use of several arguments from Mr. Locke's "Essay." About the same time, several treatises were published by some Unitarian writers, maintaining that there was nothing in the Christian religion but what was rational and intelligible, which sentiment had been advanced by Mr. Locke. The use which was made of his writings in these instances, determined Dr. Stillingfleet, bishop of Worcester, to make an attack upon the author, in his "Defence of the Doctrine of the Trinity," published in 1697. Mr. Locke wrote an answer, and the controversy was carried on till the death of the bishop: The candid of every party admitted that Mr. Locke was too powerful for the learned prelate, and M. Le Clerc, speaking of the discussion, says, "Every body admired the strength of Mr. Locke's reasonings, and his great clearness and exactness, not only in explaining his own notions, but in confuting those of his adversary. Nor were men of understanding less surprised, that so learned a man as the bishop should engage in a controversy, in which he had all the disadvantages possible: for he was by no means able to maintain his opinions against Mr. Locke, whose reasonings he neither understood, nor the subject itself about which he disputed." And an Irish prelate writing to Mr. Molyneux, the intimate friend of Mr. Locke, thus expresses himself on the subject: "I am wholly of your opinion, that he has laid the great bishop on his back; but it is with so much gentleness, as if he were afraid not only of hurting him, but even of spoiling or tumbling his clothes. Indeed, I cannot tell which I most admire; the great civility and good manners in his book, or the forcibleness and clearness of his reasoning." Never, perhaps, was a controversy managed with so much skill and art on one side, nor on the other, so unjustly, confusedly, or so little to the credit of the author. The tracts on this controversy were the last which Mr. Locke committed to press: he grew infirm more from disease than great age, and he determined to resign his office of "Commissioner of Trade, &c.," but he acquainted no person of his intention till he had given his commission into the king's own hand. His majesty pressed him to continue in the post, though he should be unable to perform its duties; but Mr. Locke could not be induced to make such a compromise, and he insisted upon first resigning the emoluments of a place that he felt himself incapable of filling. From this time, which was the year 1701, he lived altogether at Oates in Essex, and applied himself, without interruption, entirely to the study of the holy scriptures; and in the employment he found so much pleasure, that he regretted his not having devoted more of his time to it in the former part of his life; and he replied, in

answer to a young gentleman, who asked what was the shortest and surest way for a person to attain a true knowledge of the Christian religion? "Let him study the holy scripture, especially the New Testament. It has God for its author; salvation for its end; and truth, without any mixture of error, for its matter." In 1703 he suffered much from an asthmatic disorder, but the pangs of bodily complaint were alleviated by the kind attentions of lady Masham, who was the daughter of the learned Cudworth: still he foresaw that his dissolution was not far distant, and he could anticipate it without dread, and speak of it with perfect calmness and composure. Though few men had need of so little preparation for the important change as Mr. Locke, yet he felt it right to receive the sacrament at home, in company with some friends, being unable to go to church. When the ceremony was finished, he told the minister, "that he was in perfect charity with all men, and in a sincere communion with the church of Christ, by what name soever it might be distinguished." He lived some months after this, which he spent in acts of piety and devotion: when he was meditating on the wisdom and goodness of the Creator, he could not forbear crying out, "Oh the depth of the riches of the goodness and knowledge of God!" what he felt himself on this subject he was anxious to infuse into the hearts of others. On the day previously to his departure he said, "he had lived long enough, and was thankful that he had enjoyed a happy life; but that, after all, he looked upon this life to be nothing but vanity," or, as he expresses a similar sentiment, in a letter which he left behind him for his friend Mr. Anthony Collins, one that "affords no solid satisfaction but in the consciousness of doing well, and in the hopes of another life." He had no rest that night, and begged in the morning to be carried into his study, where, being placed in an easy chair, he had a refreshing sleep for a considerable time. He then requested his valuable friend, lady Masham, to read aloud some of the psalms, to which he appeared exceedingly attentive, till feeling, probably, the approach of the last messenger, he begged her to desist, and in a few minutes expired, on the 28th of October 1704, in the 73d year of his age. He was interred in the church of Oates, where there is a monument erected to his memory, with a Latin inscription, which he had prepared for the purpose.

Such was the end of as illustrious a philosopher as ever adorned our country: celebrated not only by his wisdom, but by his piety and virtue, by his love of truth, and diligence in the pursuit of it, and by a noble ardour in defence of the civil and religious rights of mankind. That Mr. Locke possessed a noble and lofty mind, superior to prejudice, and capable, by its native energy, of exploring the truth, even in the regions of the intellectual world before unknown; that his judgment was accurate and profound; that his imagination was vigorous; and that he was well furnished with the ornaments of elegant learning, were there no other proofs, might be concluded from his great and immortal work, "The Essay concerning Human Understanding." Though we cannot agree with the learned author of the "Diversions of Purley," "that Mr. Locke never did advance a single step beyond the origin of Ideas and the composition of Terms;" yet it must be admitted, that this was the main object of his essay, though not at first perceived by Mr. Locke himself, as he acknowledges: but he adds, "when I began to examine the extent and certainty of our knowledge, I found it had to near a connection with words, that makes their force and manner of signification were first well observed, there could be very little said clearly and pertinently concerning knowledge, which being conversant about truth, had constantly to do with propositions. And though it terminated in things,

yet it was for the most part so much by the intervention of words, that they seemed scarce separable from our general knowledge." And again, "I am apt to imagine, that were the imperfections of language, as the instrument of knowledge, more thoroughly weighed, a great many of the controversies that make such a noise in the world, would of themselves cease, and the way to knowledge, and perhaps peace too, lie a great deal opener than it does." Hence the author, just referred to, assumes, "that the more Mr. Locke reflected and searched into the human understanding, the more he was convinced of the necessity of an attention to language, and of the inseparable connection between words and knowledge. He says, moreover, that it was a lucky mistake which Mr. Locke made when he called his book "An Essay on the Human Understanding." For some part of the inestimable benefit of that book has, merely on account of its title, reached to thousands more than, I fear, it would have done, had he called it (what it is merely) A Grammatical Essay, or a treatise on words, or on language. The human mind, or the human understanding, appears to be a grand and noble theme, and all men, even the most insufficient, conceive that to be a proper object for their contemplation, while enquiries into the nature of language are supposed to be beneath the concern of their exalted understanding." We shall now quote Dr. Enfield's opinion of this great work. "Discarding," says he, "all systematic theories, he has, from actual experience and observation, delineated the features, and described the operations of the human mind, with a degree of precision and minuteness not to be found in Plato, Aristotle, or Des Cartes. After clearing the way by setting aside the whole doctrine of innate notions, and principles both speculative and practical, the author traces all ideas to two sources, sensation and reflection: treats at large of the nature of ideas, simple and complex; of the operation of the human understanding in forming, distinguishing, compounding, and associating them; of the manner in which words are applied as representations of ideas; of the difficulties and obstructions in the search after truth, which arise from the imperfection of these signs; and of the nature, reality, kinds, degrees, casual hindrances, and necessary limits of human knowledge." Mr. Locke's "Two Treatises of Government," will render his memory dear to the enlightened friends of civil and religious freedom: his letters on toleration, and his commentaries on St. Paul's epistles, are likewise held in high estimation.

Mr. Locke's private character cannot be wholly overlooked: he possessed a great knowledge of the world, and was intimately conversant in the business of it. He was prudent without cunning, and he engaged men's esteem by his probity. Averse from all mean compliances, his wisdom, his experience, and his gentle manners, gained him the respect of his inferiors, the esteem of his equals, the friendship and confidence of those of higher quality. He was remarkable for the ease and politeness of his behaviour; and those who only knew him by his writings, and who had conceived him to be a reserved man, were surprised, if they happened to be introduced to him, to find him extremely affable, good-humoured, and complaisant. Dr. Isaac Watts describes him as having a soul wide as the sea; calm as night, bright as day. And the same author has a fine ode in his lyric poems, written on occasion of Mr. Locke's dangerous illness, some time after he had retired to study the scriptures, of which we shall quote the first stanza.

"And must the man of wondrous mind,
Now his rich thoughts are just refin'd,
Forfake our longing eyes?"

Reason at length submits to wear
The wings of faith; and lo! they rear
Her chariot high, and nobly bear
Her prophet to the skies."

Among the honours paid to the memory of Mr. Locke, that of queen Caroline, consort of George II. ought not to be overlooked, for that princess, having erected a pavilion in Richmond park, devoted to, or in honour of, philosophy, placed in it Mr. Locke's bust, with those of Bacon, Newton, and Clarke, as the four chief of the English philosophers. He left behind him several MSS., from which his executors, Sir Peter King and Anthony Collins, esq. published, in 1705, his paraphrase and notes upon St. Paul's epistle to the Galatians, which were soon followed by those upon the Corinthians, Romans, and Ephesians, with an essay prefixed, "For the understanding of St. Paul's epistles, by consulting St. Paul himself." In the following year the posthumous works of Mr. Locke were published, comprising a treatise "On the Conduct of the Understanding," intended as a supplement to the "Essay;" "An Examination of Malebranche's Opinion of seeing all Things in God." In 1708, some familiar letters between Mr. Locke and several of his friends were published. All the works of this great man have been collected, and frequently reprinted in different sizes; in three vols. folio, in four volumes quarto, and lately in ten volumes 8vo. Biog. Brit. Life prefixed to Mr. Locke's works. Enfield's Hist. of Phil.

LOCKE, in *Geography*, a town of Prussia, in Ermeland; 11 miles from Heilsberg.

LOCKE, a military town of America, in Milton township, New York, in Onondago county; 13 miles N.E. of the S. end of Cayuga lake.

LOCKENITZ, a town and castle of Brandenburg, in the Ucker Mark; 16 miles N.E. of Prenzlau.

LOCKER, in a *Ship*, a kind of box or chest made along the side of a ship, to put or stow any thing in.

LOCKER, *Gozolans*. See HELLERBORN, and TROLLIUS.

LOCKER *Shot*, in *Sea Language*. See GARLAND.

LOCKERBIE, in *Geography*, a market town situated in the parish of Drydale, Dumfriesshire, Scotland. It is pleasantly seated on the river Annan, at the distance of 12 miles from the county town. It consists chiefly of one regular street, half a mile in length from north to south, and this is intersected, at right angles, by another street of inferior extent. According to the parliamentary returns of 1801, the whole parish contained 322 houses and 1607 inhabitants. The buildings in the town are chiefly of recent date. The parish church stands on an eminence at the head of the principal street. Two lakes formerly almost encircled the town. It has two fairs and ten markets during the year, at which upwards of 20,000 limbs are annually sold; the greater part of which are principally sent into England. A considerable quantity of linen and woollen cloths are likewise purchased for the same part of the kingdom.

LOCKEREN, a town of France, in the department of the Scheldt, and chief place of a canton in the district of Termonde. The place contains 11,041, and the canton 15,093 inhabitants, on a territory of 77 kilometres, in three communes.

LOCKHART, a town of North Carolina, in Albemarle Sound; 38 miles E.S.E. of Halifax. N. lat. 36° 2'. W. long. 76° 56'.

LOCKI, or LAKE, as the true orthography may be almost indifferently pronounced, is a name of Lakshmi, the consort of the Hindoo deity Vishnu. See LAKSHMI.

LOCKING-UP, or LOCKING-down, denotes the operation of passing boats up or down through locks.

LOCKING.

LOCKING of Wheels, in *Rural Economy*, the means of lessening them so as to prevent their running too swiftly upon the horses, when coming down steep hills. This is effected in various ways; as by chains, sledges, friction, bars, &c. See **CAUT**, **WHEEL**, and **WAGON**.

LOCKMAN, in the Isle of Man, the officer who executes the orders of the government, much like our undersheriff.

LOCKS, in the *Manège*, in French called *entravens*, are pieces of leather two fingers broad, turned round, and fluffed on the inside, to prevent their hurting the palfren of a horse, round which they are clipped. An *entrance* is composed of two *entravens* joined by an iron chain, seven or eight inches long.

LOCKSPIT, among *Miners*, is the small cut or trench, made with a space of about a foot wide, to mark out the first lines of a work.

LOCKTEWACKI, in *Ceresius*, a town of Swedish Lapland, on a lake; 65 miles W.N.W. of Pitea.

LOCLE, a town, or rather village, of Switzerland, in the principality of Neuchâtel. La Chaux de Fond, another large handsome village lying in a broad valley which reaches to Franche Comte, is connected with Locle by a range of pleasing cottages, skirting both sides of the road. Both these villages, together with the districts belonging to them, contain about 6000 inhabitants, distinguished for their skill and industry in the mechanical arts. They carry on an extensive traffic in lace, stockings, cutlery, and other articles of their own manufacture; but particularly excel in watch-making, and every branch of clock-work. All sorts of workmen necessary for the completion of that business, such as painters, enamellers, engravers, and gilders, are found in these villages; where, upon an average, about 10,000 watches are annually made. Several inhabitants of these villages have invented useful mathematical and astronomical instruments. The son of Droz, afterwards a resident at Paris, exhibited in England several automatical figures of surprising construction: one played upon the harpsichord, another drew landscapes, and a third copied any word presented to it, or wrote down whatever was dictated by any of the company.

LOCMAN, a mountain of Persia, in the province of Khorasan; 15 miles W. of Maruerud.

LOCMINE, a town of France, in the department of Morbihan, and chief place of a canton, in the district of Pontivy; 10 miles S. of Pontivy. The place contains 6429, and the canton 11,253 inhabitants, on a territory of 250 kil. metres, in seven communes.

LOCO POROS NO, a town of Naples, in the province of Bari; 11 miles S.S.E. of Monopoli.

LOCONGAI, a town of Upper Siam; 60 miles N. of Perseon.

LOCRI, **LOCRIANS**, in *Ancient Geography*, a people who are said to have derived their name from an ancient hero called "Locris," or "Locros," whose son Opis founded a town under his own name. These people formed four distinct colonies, with appropriate surnames, the three first of which, viz. *Locri ozoli*, *Locri epizephyrii*, and *Locri opuntiani*, were settled in Greece: the fourth division, denominated *epizephyrii*, inhabited Magna Græcia, near the promontory of Zephyrium. The *ozoli* occupied a considerable extent of country W. of the Phocide, along the gulf of Corinth. The *epizephyrii* derived their name from mount Cronion, about which they dwelt; the *Mabre* gulf being on the E., mount Oeta on the N., the Phocide on the W., and the *Locri opuntiani* on the S., whose territory was of small extent. The *epizephyrii* were situated near the promontory of Zephyrium, and were distributed into two classes, distinguished by

their name and their situation. One division embarked on the gulf of Corinth, and the other on the *Ægean* sea. It is therefore possible that a colony of one of these branches might establish themselves in this part of Italy. Their town, "*Locri Epizephyrii*," was situated on a hill near the above-mentioned promontory. Some say that it was founded at the same time with *Cyzicus*, under the reign of *Tullus Hostilius*, but *Strabo* dates its origin a little after *Crotona* and *Syracuse*, about the year 757 before our era. It was very flourishing, when *Dionysius the younger*, having been driven from *Syracus*, practised there all sorts of violence. But the *Locrians*, having recovered their liberty, expelled the garrison and took ample vengeance of the tyrant. *Ephorus*, says *Strabo*, reports, that *Zaleucus* formed the laws of the *Locrians* from those of *Crete*, *Sparta*, and *Athens*, one of which established a conformity of punishment to crimes, whereas before they were arbitrary and depended upon the will of the judge. The *Locrians* had built upon the coast a temple of *Proserpine*, which was pillaged by *Pyrrius* when he carried his arms into Italy. The town was not better treated by the Roman garrison, under the orders of *Flaminius*. In the year 539 of Rome the *Locrians*, having devoted themselves to the *Brutians* and *Carthaginians*, by this conduct incurred the Roman republic; so that they sent troops against them and took their city in the year 549. A little after, however, they recovered their liberty. The sequel of the history of the *Locrians* is not known; but an instance of their valour has been recorded which deserves to be mentioned. In a war between them and the *Crotoniates*, 10,000 *Locrians*, with a few additional troops, defeated 130,000 of the enemy near the river *Sagra*; an event so marvellous, that it became proverbial in giving attestation to a fact thought incredible. *Allegro non è la Sagra*; i. e. it is more true than the battle of *Sagra*.

Locri, or *Locres*, *Motta di Buazzaro*, a town of Italy, in *Brutium*. It was founded, as we have already mentioned in the preceding article, by a colony of Greeks called *Locrians*.

LOCRIAN, in *Ancient Music*, the seventh species of the diapason. It was also called *hypochoriant*, and *common*.

LOCULAMENTUM, in *Botany*, denotes a cell or partition, in a seed-pod, for the seed of a plant.

In some plants we only find one loculamentum in a pod; in some others two, three, or more.

LOCUS, **PLACE**, in the general sense. See **PLACE**.

Locus, among *Ancient Musicians*, was used to signify the interval between one degree of acuteness or gravity of sound and another. The Greeks used the word $\tau\epsilon\tau\alpha$ in the same sense, for the space through which the voice moved. See **MOTION**.

This motion the Greeks distinguished into two kinds; one continued, $\tau\epsilon\tau\alpha$, the other disjoint, $\tau\epsilon\tau\alpha\sigma\epsilon\sigma\epsilon\sigma$. Instances of the first kind are in speaking; of the second, in singing; and this they called melodic motion, or what was adapted to singing. *Locutus* in like manner divides sounds of unequal pitch, $\tau\epsilon\tau\alpha\sigma\epsilon\sigma\epsilon\sigma$, into continued and discrete, and says the first kind are improper, and the second proper, for harmony.

Aristides Quintilianus interposes a third kind of motion between the two here mentioned, such as that of a person reciting a poem.

Locus, in *Rhetoric*, a topic, or head, whence arguments are brought to prove the question in hand. Some of these are called *communis*, or common topics, as being common to all sorts of argument; thus, whether a thing be possible or impossible, more or less than something else, &c.

Besides these, three others are mentioned by rhetoricians, *judicial*,

justum, utile, and honestum; to which some add *jucundum*; but Vossius will have this last to be comprehended under *utile*. See TOPIC.

Locus geometricus denotes a line, by which a local or indeterminate problem is solved. See LOCAL PROBLEM.

If a point vary its position, according to some determinate law, it will describe a line, which is called its *locus*: or a locus is a line, any point of which may equally solve an indeterminate problem.

This, if a right line suffice for the construction of the equation, is called *locus ad rectum*: if a circle, *locus ad circumferentiam*; if a parabola, *locus ad parabolam*; if an ellipsis, *locus ad ellipsem*; and so of the rest of the conic sections.

The loci of such equations as are right lines, or circles, the ancients called *plane loci*; and of those that are parabolas, hyperbolas, &c. *solid loci*.

Apollonius of Perga wrote two books on *plane loci*, in which the object was, to find the conditions under which a point, varying in its position, is yet limited to have a right line, or a circle given in position. These books are lost, but attempts have been made at restorations by Schooten, Fermat, and R. Simson; the treatise "De Locis Planis," of the latter geometer, published at Glasgow, 1749, is a very excellent performance, in all respects worthy of its celebrated author. Besides the above-mentioned writers, the doctrine of loci has been treated of by various other mathematicians, as Craig, Maclaurin, Des Cartes, De l'Hôpital, &c. the latter of whom has two chapters on this subject in his *Conic Sections*. Leslie in his *Geometry* has also a chapter on plane loci, which contains several of the most simple and interesting propositions of this kind.

Before we proceed to investigate the loci of the higher orders, it will be proper to state a few of the principal properties and uses of plane or geometrical loci; in doing which, however, we must necessarily confine ourselves to those only of the most general description, as the limits of this article will not admit of a minute and particular investigation.

PROP. I.

If a straight line, drawn through a given point to a straight line given in position, be divided in a given ratio, the locus of the point of section is a right line given in position. *Plate XII. Analysis, fig. 1.*

Let the point A, and the straight line B D, be given in position, and let A B, limited by these, be cut in a given ratio at C; this point will be in a straight line given in position.

Analysis.—From A, let fall the perpendicular A D upon B D; and through C draw C E parallel to B D; then $AC : AB :: AE : AD$, and, consequently, the ratio of A E to A D is given; but A D is given both in position and magnitude, and hence A E and the point E are also given, and therefore C E, which is perpendicular to A D, is given in position.

Compassion.—Let fall the perpendicular A D, which divides E in the given ratio, and erect the perpendicular C E, so shall this straight line be the locus required. For C E being parallel to B D, $AC : AB :: AE : AD$; that is, in the given ratio.

PROP. II.

If a straight line, drawn through a given point to the circumference of a given circle, be divided in a given ratio, the locus of the point of section will also be the circumference of a given circle. *Fig. 2.*

Let A B, terminating in a given circumference, be cut in a given ratio, the segment A C will likewise terminate in a given circumference.

Analysis.—Join A with D, the centre of the given circle; and draw C E parallel to B D; then it is evident that $AC : AB :: AE : AD$; whence the ratio of A E to A D being given, A E and the point E are given. Again, since $AC : AB :: CE : BD$, the ratio of C E to B D is given, and consequently C E is given in magnitude. Wherefore the one extremity E being given, the other extremity of C E must trace the circumference of a given circle.

Compassion.—Join A D, and divide it at E in the given ratio, and in the same ratio make D B to the radius E C, with which and from the centre E describe a circle.

For draw A B cutting both circumferences, and join C E and B D. Because $CE : BD :: AE : AD$, alternately $CE : AE :: BD : AD$; wherefore the triangles C A E and B A D, having likewise a common angle, are similar; and consequently, $AC : CB :: AE : AD$, that is, in the given ratio.

PROP. III.

If through a given point two straight lines be drawn in a given ratio, and containing a given angle; should the one terminate in a given circumference, the other will also terminate in a given circumference. *Fig. 3.*

Let the angle C A B, its vertex A, and the ratio of its sides be given; if A B be limited by a given circle, the locus of C will also be a given circle.

Analysis.—Join A with D, the centre of the given circle; draw A E at the given angle with A D, and in the given ratio; and join D B and E C. Because the point A and the centre D are given, the straight line A D is given; and since the angle D A E, being equal to B A C, is given; A E is given in position. But A D being to A E in the given ratio, A E must be given also in magnitude, and consequently the point E is given. Again, the whole angle B A C being equal to D A E, the part B A D is equal to C A E, and because $AB : AC :: AD : AE$, alternately $AB : AD :: AC : AE$; wherefore the triangles A D B and A E C are similar, and hence $AB : BD :: AC : CE$, or alternately, $AB : AC :: BD : CE$; consequently the fourth term C E is given in magnitude; and its extremity E being given, the other must lie in a given circumference.

Compassion.—Having drawn A E at the given angle with A D, make A D to A E in the given ratio; and in the same ratio let D B be made to E C; a circle described from the centre D with the distance E C is the locus required.

For $AD : AE :: DB : EC$, and alternately, $AD : DB :: AE : EC$. But the angle B A D is equal to C A E; because the whole B A C is equal to D A E; consequently the triangles A D B and A E C are similar; and $AB : AD :: AC : AE$, or alternately, $AB : AC :: AD : AE$; that is, in the given ratio.

PROP. IV.

The middle point of a given straight line, which is placed between the sides of a right angle, lies in the circumference of a given circle. *Fig. 4.*

Let A D be placed in the right angle E D F, touching E D and D F, the locus of its bisection C is a given circle.

Analysis.—Join D C; then because the base of the triangle A D B is bisected in C, a circle described from C as a centre, and with the radius A C, or C B, will pass through the point D; for the angle A D B being a right angle, it necessarily

necessarily falls in the circumference of the semicircle ADE ; consequently AC , CB and CD , are all equal to each other. But AC , being half of AB , is given, therefore DC is also given, whence the locus of the point of bisection C is a circle described from D with the radius DC .

Construction.—From D , with a distance equal to half the given line, describe a circle; this is the locus required.

For draw the radius DC , make $AC = DC$, and produce AC to B . Because $AC = DC$, the angle $ADC = DAC$; but the angles DAC and DBC are together equal to a right angle, and therefore equal to ADC and BDC ; whence the angle DBE is equal to the angle BDC , and consequently, the side DC is equal to BC . The segments AC , BC are thus each of them equal to DC , and hence AB is itself double DC , or is equal to the given straight line.

PROP. V.

If from two given points there be inflected two straight lines in a given unequal ratio, the locus of their point of concurrence is a given circle.

Let AC and BC , drawn from the points A and B , have a given ratio, but not that of equality; then will C , the point of concurrence, be in the circumference of a given circle. *Fig. 5.*

Analysis.—Draw CD , making the angle BCD equal to BAC ; and meeting AB produced in D . The triangles DAC and DCB , having the angle at D common, and the angles at A and C equal, are evidently similar; and hence $AD : AC :: CD : CB$, and alternately, $AD : CD :: AC : CB$, that is, in the given ratio; but $AD : CD :: CD : BD$, and consequently, AD is to BD in the duplicate of the given ratio AD to CD , and which is therefore likewise given. Consequently BD , and the point D , are given; and BD being thence given, its extremity C must lie in the circumference of a circle described with that radius.

Construction.—Divide AB in the given ratio in E , and in the same ratio make ED to BD ; the circle described from the centre D , and with the radius DE , is the locus required.

For since $AE : EB :: ED : BD$, it follows that $AD : ED :: CD : ED$, or as $CD : BD$; hence the triangles DAC and DCB , thus having their sides, which contain their common angle D , proportional, are similar; and therefore $AC : AD :: BC : CD$, or alternately, $AC : BC :: AD : CD$ or DE , that is, in the given ratio.

PROP. VI.

If two straight lines, containing a given rectangle, be drawn from a given point at a given angle: should the one terminate in a straight line given in position, the other will terminate in the circumference of a given circle. *Fig. 6.*

Let the point A , the angle BAC , and the rectangle under its sides BA , AC , be given; if the direction BD be given, then will the locus of C be a given circle.

Analysis.—From A let fall the perpendicular AD upon BD : draw AE , to contain with AD an angle equal to the given angle, and a rectangle equal to the given space, and join CE .

Since AD is evidently given in position and magnitude, AE is likewise given in position and magnitude; and the rectangle $AD \times AE$ being equal to $AB \times AC$, therefore $AD : AB :: AC : AE$; but the angle DAE is equal to BAC , and hence DAB is equal to EAC . Wherefore the triangles ABD , AEC , having each an

equal angle, and the sides containing it proportional, are similar; and consequently the angle ACE is equal to the right angle ADB . Whence the locus C is a circle, having AE for its diameter.

Construction.—Having let fall the perpendicular AD , draw AE , making the angle DAE equal to the given angle, and the rectangles DA , AE , equal to the given space. On AE as a diameter describe a circle; this is the locus required. For join CE , and the triangles DAB , EAC , being right-angled at D and C , and having the vertical angles at A equal, are evidently similar; and consequently $AD : AB :: AC : AE$; and hence the rectangle $AB \times AC = AD \times AE$, that is, it is equal to the given space.

The foregoing proposition we have drawn with little variation from the chapter on loci given by professor Leslie in his *Geometry*, and several of the following propositions are likewise derived from the same source.

7. If a straight line drawn from a given point to a straight line given in position, contain a given rectangle, the locus of its point of section will be a given circle.

8. If two straight lines in a given ratio, and containing a given angle, terminate in two diverging lines, which are given in position, the locus of their vertex will likewise be a right line given in position.

9. If from two points there be drawn two straight lines, of whose squares the difference is given, the locus of their point of concurrence will be a right line given in position: or, which is the same, if the base of a triangle, and the difference of the squares of the two sides be given, the vertex of the triangle will fall in a right line given in position.

10. If the base and vertical angle of a triangle be given, the locus of its vertex will be the circumference of a given circle.

11. If the difference of the sides, and the radius of the inscribed circle of a triangle be given, the locus of its vertex is a right line given in position.

12. If two given unequal perpendiculars be drawn to a right line given in position, and their opposite extremities be joined, the locus of the point of intersection will be a right line given in position.

13. If in any triangle the base be given, and the sum of the squares of the other two sides, the locus of the vertex is a given circumference.

14. If from given points there be drawn straight lines, whose squares are together equal to a given space, their point of concurrence will terminate in the circumference of a given circle.

15. If right lines be drawn from a given point to cut a given circle, and from the points of intersection there be taken, upon these lines, on either side, lines in a constant given ratio to the distance between the respective points of intersection and the given point; the locus of the points so determined, will be a circle.

16. If two circles cut each other, and through either point of intersection a right line be drawn, cutting both the circles, then, if a right line be always taken thereon from one of those points in a given ratio to the part intercepted between the circles, the locus of the points so determined will be a circle.

17. If the circles cut each other as above, and a right line be drawn through either intersection, cutting both the circles, then if a right line be always taken thereon from one of those points in a given ratio to the part between the other point and intersection, the locus of the point so determined will be a circle.

18. If triangles be inscribed in a given segment of a circle, and from the vertex on either side (produced if necessary) there be taken, either way, a right line always in a constant ratio to either of the sides, or to their sum, or difference, the loci of the points so described will be circles.

The above contain many of the most simple cases of geometrical loci; and we will now shew the application of them to the construction of certain geometrical problems.

Of the Construction of geometrical Problems.

PROB. I.

Having given the base, perpendicular, and vertical angle of a plane triangle; it is required to construct it. *Fig. 7.*

Analysis.—Suppose the thing done, and let ABC represent the proposed triangle, of which the base AB , the perpendicular CD , and vertical angle ACB , are given; then it is obvious, in the first place, that the locus of the vertex will be the right line CF , drawn parallel to AB , at the given perpendicular distance. Also, since the angle ACB is given, the locus of the vertex will be in the circumference of the circle ACB , described upon AB , capable of containing the given angle ACB ; and consequently, at either point where the line and circle intersect each other, will be the vertex of the triangle required.

Construction.—On the given base AB describe a circle that shall contain the given vertical angle. And parallel to AB , and at a distance equal to the given perpendicular, draw the right line FCE ; join AC , CB , so is ACB the triangle required. For, the point C being in the segment ACB , the angle ACB is equal to the given vertical angle; and being also in the line FCE , the perpendicular CD is equal to the given perpendicular, and the base AB is equal to the given base.

If the right line cut the circle in one point, it will also cut it in two points, and therefore in this case there are two triangles which answer the conditions of the problem; but if it touches the circle only, then there is but one such triangle; and if the line FCE falls above the circle, then the problem is impossible.

PROB. II.

Having given the perimeter of a right-angled triangle, and the perpendicular let fall from the right angle to the opposite side, to construct it. *Fig. 8.*

Analysis.—Suppose the thing done, and let ACB be the proposed triangle; produce the line AB both ways to D and E , making $AD = AC$, and $CB = BE$; then will DE represent the perimeter which is given by the question; join DE and CE . Then because $DA = AC$, the angle $ADC = DCA$; but the angle CAB is equal to the two angles ADC and DCA , or it is equal to double the angle DCA : in the same manner it may be shewn that the angle ABC is equal to double the angle BCE ; but the angles CAB and ABC are together equal to a right angle, and consequently, since these are double of the angles DCA and BCE , it follows, that the sum of the latter two angles is given, being equal to half a right angle; and therefore also the whole angle DCE is given, being equal to a right angle and half a right angle; therefore the locus of the point C is in the circumference of a given circle. And since the perpendicular CG is also given, the locus of the point C is the right line CF , parallel to the base AB , whence the point C is determined, being found in the intersection of the right line CF and the given segment DCE .

VOL. XXI.

Construction.—On the right line DE , equal to the given perimeter, describe a segment capable of containing an angle equal to a right angle and half a right angle; and parallel to DE , and at the given perpendicular distance, draw the right line FC cutting the segment in C and C' : join DC , CE ; and from C draw also CA , AB , making the angles DCA and BCE respectively equal to the angles CDA and CEB , so shall ACB be the triangle required.

For since the angle DCA is equal to the angle DAC , the side DA is equal to AC , and for the same reason the side CB is equal to BE , and therefore the three sides of the triangle ABC are equal to the whole DE , or to the given perimeter; also, since the angle DCE is equal to a right angle and half a right angle, the angles CDA and CEB are together equal to half a right angle; but the angle CAB is double the angle CDA , and the angle CBA is double the angle CEB , and consequently these two together are equal to a right angle; therefore the third angle of the triangle ACB is a right angle. Hence, since the perpendicular CG is equal to the given perpendicular, by construction, and the sum of the three sides AB , AC , BC , equal to the given perimeter, and the angle ACB equal to the given angle, it follows that the triangle ABC is that which was to be constructed.

This construction serves equally for any other triangle, provided the vertical angle be given: and the limits of possibility are the same as in the preceding problem.

We will add one other example from Dr. Pemberton's paper on this subject, printed in vol. liii. of the Philosophical Transactions, and will then proceed to the consideration of loci of the higher orders.

PROB. III.

Let it be proposed to draw a triangle given in species, so that two of its angles may touch a right line given in position, and the third angle a given point.

This problem, which would be extremely difficult to solve algebraically, admits of more than one very concise geometrical solution; and as they will occupy but little space, it is presumed they will not be unacceptable to the reader of this article.

In the first place, suppose a circle (*fig. 9.*) to pass through the three points A , E , D , which shall intersect AC in G . Then EG , DG , being joined, the angle DEG will be equal to the given angle DAC , both inscribing on the same arc DG : also the angle EDG is the complement to the two right ones of the given angle BAC : these angles therefore are given, and the whole figure $EFGD$ given in species. Consequently the angle EGF , and its equal ADE will be given, together with the side DE of the triangle in position.

Again, suppose a circle (*fig. 10.*) to pass through the three points A , E , F , cutting AD in H , and EH , FH joined. Here the angle EFH will be equal to the given angle EAH ; and the angle FEH equal to the given angle FAH . Therefore the whole figure $EHFD$ is given in species; and consequently the angle ADE as before.

Lastly, suppose a circle (*fig. 11.*) to circumscribe the triangle, and intersect one of the lines, as AC in I . Then DI being drawn, the angle DIF will be equal to the given angle DEF in the triangle; consequently DI is inclined to AC in a given angle, and is given in position, as also the point I given; whence IE being drawn, the angle FIE will be the complement of the angle EDF in the triangle to two right ones. Therefore IE is given in position.

i i sition,

tion, and by its interfection with the line A B, gives the point E, with the position of D E, and thence the whole triangle as before. Here it may be observed, that the angle D of the triangle E D F, given in species touching a given point D, and another of its angles touching A C, the line A E here found is the locus of the third angle E.

Of the higher Order of Loci.

Loci are very commodiously divided into orders, according to the dimensions to which the variable quantity rises in the formula which expresses the equation of the curve.

Thus it will be a *locus of the first order*, if the equation be $x = a y$; a *locus of the second or quadrate order*, if $y^2 = a x$, or $y = a - x$, &c.; a *locus of the third or cubic order*, if $y^3 = a x$, or $y = a x^2 - x$, &c.

The better to conceive the nature of the locus, suppose two unknown and variable right lines A P, P M (*figs. 12 and 13*) making any given angle A P M with each other; the one whereof, as A P, we call x , having a fixed origin in the point A, and extending itself indefinitely along a right line given in position; the other P M, which we call y , continually changing its position, but always parallel to itself; and moreover an equation only containing these two unknown quantities x and y , mixed with known ones, which expresses the relation of every variable quantity A P (x) to its correspondent variable quantity P M (y): the line passing through the extremities of all the values of y , i. e. through all the points M, is called a geometrical locus, in general, and the locus of that equation in particular.

All equations, whose loci are of the *first order*, may be reduced to some one of the four following formulæ:

$$1. y = \frac{b x}{a}, \quad 2. y = \frac{b x}{a} + c, \quad 3. y = \frac{b x}{a} - c, \quad 4. y = c - \frac{b x}{a},$$

where the unknown quantity y is supposed always to

be freed from fractions, and the fraction that multiplies the other unknown quantity x to be reduced to this expression $\frac{b}{a}$, and all the known terms to this c .

The locus of the first formula being already determined; since it is evident, that it is a right line which cuts the axis in A, and which makes with it an angle, such that the two unknown quantities x, y , may be always to one another in the proportion of a to b ; to find that of the second, $y =$

$\frac{b x}{a} + c$. In the line A P (*fig. 14.*) take A B = a , and draw B E = b , A D = c , parallel to P M. On the same side A P, draw the line A E of an indefinite length towards E, and the indefinite straight line D M parallel to A E. I say the line D M is the locus of the aforesaid equation or formula; for if the line M P be drawn from any point M thereof parallel to Q A, the triangles A B E, A P F, will be similar; and therefore A B (a) : B E (b) :: A P (x)

$$: P F = \frac{b x}{a}; \text{ and consequently } P M (y) = P F \left(\frac{b x}{a} \right) + F M (c).$$

To find the locus of the third form, $y = \frac{b x}{a} - c$, proceed thus. Assume A B = a (*fig. 15.*) and draw the right lines B E = b , A D = c , parallel to P M, the one on one

side A P, and the other on the other side; and through the points A, E, draw the right line A E of an indefinite length towards E, and through the point D the line D M parallel to A E: I say, the indefinite right line G M shall be the locus sought; for we shall have always P M (y) = P F

$$\left(\frac{b x}{a} \right) - F M c.$$

Lastly, to find the locus of the fourth formula, $y = c - \frac{b x}{a}$; in A P (*fig. 16.*) take A B = a , and draw B E = b ,

A D = c , parallel to P M, the one on one side A P, and the other on the other side; and through the points A, E, draw the line A E indefinitely towards E, and through the point D draw the line D M parallel to A E. I say D G shall be the locus sought; for if the line M P be drawn from any point M thereof, parallel to A Q, then we shall have

$$\text{always } P M (y) = F M (c) - P F \left(\frac{b x}{a} \right).$$

Hence it appears, that all the loci of the *first degree* are straight lines; which may be easily found, because all their equations may be reduced to some one of the foregoing formulæ.

All loci of the *second degree* are conic sections, *viz.* either the parabola, the circle, ellipsis, or hyperbola: if an equation therefore be given, whose locus is of the second degree, and it be required to draw the conic section, which is its locus, first draw a parabola, ellipsis, and hyperbola; so that the equations expressing the natures thereof may be as compound as possible; in order to get general equations, or formulæ, by examining the peculiar properties whereof we may know which of these formulæ the given equation ought to have regard to; that is, which of the conic sections will be the locus of the proposed equation. This known, compare all the terms of the proposed equation with the terms of the general formula of that conic section, which you have found will be the locus of the given equation; by which means you will know how to draw the section, which is the locus of the equation given.

For example: let A P (x), P M (y), be unknown, and variable straight lines (*fig. 17.*), and let m, n, p, r, s , be given right lines: in the line A P take A B = m , and draw B E = n , A D = r , parallel to P M; and through the point A draw A E = c , and through the point D the indefinite right line D G parallel to A E. In D G take D C = s , and with C G as a diameter, having its ordinates parallel to P M, and the line C H = p , as the parameter, describe a parabola C M, and it will be the locus of the following general formula:

$$y^2 - \frac{2 n}{m} x y + \frac{n^2}{m^2} x^2 - 2 r y + \frac{2 n r}{m} x + r^2 = c.$$

$$- \frac{e p}{n} x + p s.$$

For if from any point M there be drawn the right line M P, making any angle A P M with A P; the triangles A B E, A P F, shall be similar; therefore A B (m) : A E (c) ::

$$A P (x) : A F, \text{ or } D G = \frac{c x}{m}; \text{ and } A B (m) : B E (n) :: A P (x) : P F = \frac{n x}{m}. \text{ And consequently, } G M \text{ or } P M = P F$$

$$PF - FG = y - \frac{nx}{m} - r, \text{ and } CG \text{ or } DG - DC =$$

$$\frac{ex}{m} - s. \text{ But from the nature of the parabola } GM^2 =$$

$CG \times CH$; which equation will become that of the general formula, by putting the literal values of those lines.

Again: if through the fixed point A you draw the indefinite right line A Q (fig. 18.) parallel to P M, and take A B = m, and draw B E = n, parallel to A P, and through the determinate points A E, the line A E = e; and if in A P you take A D = r, and draw the indefinite straight line D G parallel to A E, and take D C = s; this being done, if with the diameter C G, whose ordinates are parallel to A P, and parameter the line C H = p, you describe a parabola C M; this parabola shall be the locus of this second equation, or formula:

$$x^2 - \frac{2n}{m}xy + \frac{e^2}{m^2}y^2 - 2rx + \frac{2nr}{m}y + r^2 = 0.$$

$$- \frac{ep}{m}y + ps.$$

For if the line M Q be drawn from any point M, therein, parallel to A P; then will A B (m) : A E (e) : A Q or P M (y) : A F or D G = $\frac{ey}{m}$. And A B (m) : B E

$$(n) :: A Q (y) : Q F = \frac{ny}{m}. \text{ And therefore } GM \text{ or } QM$$

$$- QF - FG = x - \frac{ny}{m} - r; \text{ and } CG \text{ or } DG -$$

$$DC = \frac{ey}{m} - s. \text{ And so by the common property of}$$

the parabola, you will have the foregoing second equation, or formula. So likewise may be found general equations, or formulae, to the other conic sections.

Now if it be required to draw the parabola, which we find to be the locus of this proposed equation $y^2 - 2ay - bx + c^2 = 0$; compare every term of the first formula with the terms of the equation, because y^2 in both is

without fractions; and then will $\frac{2n}{m} = 0$, because the rect-

angle xy not being in the proposed equation, the said rectangle may be esteemed as multiplied by 0; whence $n = 0$, and $m = e$; because the line A E falling in A B, that is, in A P in the construction of the formula, the points B, E, do coincide. Therefore, destroying all the terms affected with

$\frac{n}{m}$ in the formula, and substituting m for e , we shall get $y^2 - 2ry - px + r^2 + ps = c$.

Again, by comparing the correspondent terms $-2ry$, and $-2ay$, as also $-px$, and $-bx$, we have $r = a$, and $p = b$; and comparing the terms wherein are neither of the unknown quantities x, y , we get $r^2 + ps = c$;

and substituting a and b for r and p , then will $s = \frac{c^2 - a^2}{b}$,

which is a negative expression, when a is greater than c , as is here supposed. There is no need of comparing the first terms y^2 and y^2 , because they are the very same. Now the values of m, n, r, p, s , being thus found, the sought locus

may be constructed by means of the construction of the formula, and after the following manner.

Because B E (n) = 0 (fig. 19.) the points B, E, do coincide, and the line A E falls in A P; therefore through the fixed point A draw the line A D $r = a$ parallel to P M, and draw D G parallel to A P, in which take D C (s) =

$$\frac{a^2 - c^2}{b}; \text{ then with } DC, \text{ as a diameter, whose ordinates}$$

are right lines parallel to P M, and parameter the line C H (p) = b, describe a parabola: I say, this will be the locus of the given equation, as is easily proved. If in a given equation, whose locus is a parabola, x^2 be without a fraction; then the terms of the second formula must be compared with those of the given equation.

Thus much for the method of constructing the loci of equations which are conic sections. If, now, an equation, whose locus is a conic section, be given, and the particular section whereof it is the locus, be required:

All the terms of the given equation being brought over to one side, so that the other be equal to 0, there will be two cases.

Case 1. When the rectangle xy is not in the given equation. 1. If either y^2 or x^2 be in the same equation, the locus will be a parabola. 2. If both x^2 and y^2 are in the equation with the same signs, the locus will be an ellipsis, or a circle. 3. If x^2 and y^2 have different signs, the locus will be an hyperbola, or the opposite sections regarding their diameters.

Case 2. When the rectangle xy is in the given equation. 1. If neither of the squares x^2 or y^2 , or only one of them, be in the same, the locus of it will be an hyperbola between the asymptotes. 2. If y^2 and x^2 be therein, having different signs, the locus will be an hyperbola, regarding its diameters. 3. If both the squares x^2 and y^2 are in the equation, having the same signs, then, according as the co-efficient of x^2 is greater, equal or less than the square of half the co-efficient of xy , the locus shall be an ellipse, parabola, or hyperbola. And in any case the locus of the equation is some conic section.

We will add a problem or two, by way of illustration, with which we must conclude this article.

PROBLEM I.

If A B be the axis of a conic section, from B draw B D to meet the curve in D; and erect D C perpendicular to A B, and produce it from C till C P is in a given ratio to B D; the locus of the point P will be a conic section.

1. For the ellipse (fig. 20.); put the axis A B = a, and its conjugate Q O E = b, B C = x, and the ratio B D : C P :: d : a. Then by the known property of the ellipse,

$$a^2 : b^2 :: ax - x^2 : CD^2 = \frac{b^2}{a^2} (ax - x^2);$$

$$\text{consequently, } BD^2 = \frac{b^2 ax}{a^2} - \frac{b^2}{a^2} x^2 + x^2 = \frac{b^2 ax}{a^2} +$$

$$\frac{a^2 - b^2}{a^2} x^2, \text{ and, therefore, } CP^2 = \frac{a^2}{d^2} + BD^2 =$$

$$\frac{b^2 ax}{d^2} + \frac{(a^2 - b^2)x^2}{d^2} = \frac{a^2 - b^2}{d^2} \left(\frac{b^2 a}{a^2 - b^2} x - x^2 \right), \text{ which,}$$

if a be greater than b , is an equation to the hyperbola, the axes of which are $\frac{b^2 a}{a^2 - b^2}$ and $\frac{b^2 a}{d \sqrt{a^2 - b^2}}$.

And if b be greater than a , the equation becomes

$$C P^2 = \frac{b^2 a x - (b^2 - a^2) x^2}{d^2} = \frac{b^2 - a^2}{d^2} \left\{ \frac{b^2 a}{b^2 - a^2} x - x^2 \right\}$$

which is an equation to the ellipse whose axes are

$$\frac{b^2 a}{b^2 - a^2} \text{ and } \frac{b^2}{d \sqrt{(b^2 - a^2)}}.$$

Again, if $b = a$, the ellipse becomes a circle, and the equation for the value of $C P$ becomes $C P^2 = \frac{b^2 a x}{d^2}$, which is an equation to the parabola, whose parameter is $\frac{b^2 a}{d^2}$.

1. For the hyperbola (fig. 21.); the same notation remaining, $D C^2 = \frac{b^2}{a^2} a x + \frac{b^2}{a^2} x^2$ by the property of the

curve; consequently $C P^2 = \frac{a^2}{d^2} \times B D^2 =$

$$\frac{b^2}{d^2} a x + \frac{b^2}{d^2} x^2 = \frac{a^2 + b^2}{d^2} \left\{ \frac{b^2 a x}{a^2 + b^2} + x^2 \right\}$$

which expresses an equation to an hyperbola, whose axes are

$$\frac{b^2 a}{a^2 + b^2} \text{ and } \frac{b}{d \sqrt{(a^2 + b^2)}}.$$

3. For the parabola (fig. 22.); put the parameter $= p$, then $C D^2 = p x$, and $B D^2 = p x + x^2$; therefore $C P^2 = \frac{a^2}{d^2} (p x + x^2)$ the equation to an hyperbola whose axes are p and $\frac{a p}{d}$.

PROB. II.

If on any given right line, $A B$, there be taken any variable distance $A L$, and from L , in the same direction, any given invariable distance $L M$; and if with the centres L and B , and radii $L A$, $B M$, arcs be described, it is required to determine the nature of the curve, which is the locus of P , the point of intersection.

Let $A B = a$ (fig. 23); $L M = b$; $B M = B P = \varphi$, and having drawn $P O$ perpendicular to $A B$, put $B O = x$. Then $B L = \varphi + b$; $L O = \varphi + b - x$; $L P = A L = a - b - x$; and because $L P^2 - L O^2 = B P^2 - B O^2$, we have in symbols $(a - b - x)^2 - (\varphi + b - x)^2 = \varphi^2 - x^2$; whence $a^2 - 2(a - x)b = \varphi^2 + 2(a - x)\varphi$; and adding $-b^2 + b^2 + (a - x)^2$ to one side, and its equal $(a - x)^2$ to the other side, there results $a^2 - b^2 + (a - b - x)^2 = (a - x + \varphi)^2$.

Now take $A C = L M = b$, draw $C D$ perpendicular to $A B$, and make $A D = A B = a$; then $C D^2 = a^2 - b^2$; $C O^2 = (a - b - x)^2$, and $(O A + B P)^2 = (a - x + \varphi)^2$ whence we have $D O = A O + P B$; or $P B = D O - A O$.

Hence it will be easy to derive an algebraical equation for the rectangular co-ordinates of the curve; for we have only to put $P O = y$, to substitute $\sqrt{(x^2 + y^2)}$ for x , and to clear the equation of radicals. The equation thus found will shew the curve to be of the fourth order; but the

curve and its principal properties may be more readily deduced from the property above invelligated; viz. $P B = D O - A O$. The curve will consist of two equal and similar parts, lying on different sides of $A B$, it will be a sort of oval, enclosing the point B on every side.

The following are some of the simplest cases of the higher order of loci.

1. The base, and sum of the sides of a plane triangle being given, the locus of its vertex is an *ellipse*.

2. The base and difference of the sides of a plane triangle being given, the locus is an *hyperbola*.

3. The locus of that point, from which, if perpendiculars be drawn to three right lines given in position, and such that the sum of their squares shall be equal to a given space, is an *ellipse*.

And the same is true, whatever be the number of lines given in position.

4. If a triangle given in species have two of its angles upon a straight line given by position, and the side adjacent to those angles passing through a given point, the locus of the angle, opposite that side, is an *hyperbola*.

5. Let A, B , be two given points in the right line $A B$, given in position; let C, D , be two given points without that line; and also let $C V, D V$, be drawn meeting in F and G , so that the rectangle $A F \times B G$ is given, the locus of the point will in all cases be a *conic section*.

6. Let $A B$ be a given straight line, and P a given point without it; let $C P D$ be drawn, meeting $A B$ in C ; and let $C P$ be to $P D$ as $A C$ to $C B$; the locus of the point D is a given *hyperbola*.

7. When the base of a triangle is given, and one of the angles at the base doubles the other, the locus of the vertex is an *hyperbola*.

8. The locus of the angles of parallelograms, formed by drawing tangents at the vertices of any two conjugate diameters of an ellipse, is also an *ellipse concentric with the former*.

The above cases, and several other curious properties of this kind, the reader will find invelligated in Leybourn's "Mathematical Repository."

The method of constructing geometrical loci, by reducing them to equations as compound as possible, we owe to Mr. Craig, who first published it in his Treatise of the Quadrature of Curves, 1693. It is explained at large in the seventh and eighth books, of the Conic Sections of the marquis de l'Hospital. This subject is particularly illustrated in Maclaurin's Algebra, part iii. See also Des Cartes's Geometry; Stirling's Illustratio Linearum Tertii Ordinis; De Witt's Elementa Curvarum: Bartholomæus Juliar, in his Aditus ad nova Arcana Geometrica delegenda, has shewn how to find the loci of equations of the higher order. See also the other writers mentioned in the preceding part of this article.

LOCUST, LOCUSTA, in *Entomology*, a genus of insects, referred to that of *gryllus*; which see.

Under that article the reader will find a particular account of the devastations occasioned by swarms of locusts in their marches, and he will perceive the propriety of the frequent allusions to them that occur in the sacred writings. Dr. Shaw, Niebuhr, Ruffell, and many other travellers into the eastern countries, represent their taste as agreeable, and inform us that they are frequently used for food. Dr. Shaw observes, that when they are sprinkled with salt and fried, they are not unlike, in taste, to our fresh-water cray-fish. Ruffell says, that the Arabs salt them, and eat them as a delicacy. We learn also from Niebuhr, that they are gathered by the Arabs in great abundance, dried, and kept for

for winter provision. Hence we may naturally suppose, that these locusts were the food of John the Baptist.

LOCUST, Water, *Locusta Aquatica*, the name given by authors to a species of water-insect, somewhat resembling the locust kind in shape. It is about three inches long, its tail an inch and quarter, and its legs are of different lengths, the anterior part being the shortest of all; its body is slender, and its fore-legs are always carried straight forward, so as to reach beyond the head in the form of antennæ; these, as well as the other legs, end each in two claws; the eyes are small, and not very prominent, and the upper wings are crustaceous; the under ones membranaceous, thin, and transparent; the middle joint of the leg is such, that the creature can only move them upwards, not downwards, and there runs an acute tongue or proboscis under the belly, as is the case in the water-scorpion and notonecta. See *NEPA Linearis*.

LOCUST, in *Botany*. See *CERATONIA Siliqua*. See also *GLEDITSIA* and *HYMENÆA*.

LOCUSTA. See *VALERIANA*.

LOCUSTA-Pulex, a name given by Swammerdam to a genus of insects, described since by Mr. Ray under the name *cicadula*.

LOCUSTÆ is used by botanists for the tender extremities of the branches of trees; such as, according to the erroneous supposition of some, John the Baptist fed on in the wilderness.

Some also used locustæ for the beards and pendulous seeds of oats, and of the gramina paniculata; to which the name is given on account of their figure, which something resembles that of a locust.

LOCUSTELLA, the *Grass-hopper Lark*, in *Ornithology*, the name of a small bird of the lark kind, the *ALAUDA Trivialis* of Linnæus; which see.

LOCUTIUS, in *Mythology, the god of speech among the Romans, called by Livy *Aius Locutius*; which see.*

LOCUTORIUM. The monks and other religious in monasteries, after they had dined in their common hall, had a withdrawing room, where they met and talked together among themselves, which room, for that sociable use and conversation, they called *locutorium*, a *loquendo*; as we call such a place in our houses parlour, from the French *parler*; and they had another room, which was called *locutorium forinsecum*, where they might talk with laymen.

LODARIA, in *Geography, a town of Hindoostan, in Bahar; 24 miles N.N.E. of Hajypour.*

LODDIGESIA, in *Botany*, is justly devoted by Dr. Sims in Curtis's Magazine, to commemorate the merits of a most excellent and scientific cultivator of plants, whose liberality is equal to his knowledge, Mr. Conrad Loddiges of Hackney. Curt. Mag. v. 24 965. Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Est. Ch. Standard many times smaller than the wings or keel. Filaments all in one set, with a dorsal fissure. Legume stalked, turgid.

1. *L. oxalidifolia*. Oxalis-leaved Loddigesia. Curt. Mag. t. 965.—The only known species, a native of the Cape of Good Hope, from whence its seeds were first received by George Hibbert, esq. The plant is tolerably hardy in the conservatory, readily propagated by cuttings, and flowers freely in May and June. Mr. Loddiges himself has also raised it, many years ago, from Cape seeds. The stem is shrubby, low, much branched. Leaves scattered, stalked, ternate, inversely heart-shaped, rather glaucous, smooth, tipped with a minute point. Stipules intrafoliaceous, small, setaceous, deciduous. Clusters terminal, somewhat umbel-

late, of few flowers. Bractææ small, slender, almost capillary. Calyx nearly bell-shaped, obtuse at the base, coloured, smooth, its three lower teeth rather the longest. Standard white, not twice the length of the calyx. Wings and keel about thrice as long as the standard, white, the fore part of the keel violet. Style bent upward at a right angle. Stigma simple. Legume stalked, ovate, oblique, pointed, turgid, smooth. Seeds about four, kidney-shaped.

LODDON, in *Geography*, a small market-town in the hundred to which it gives name, in the county of Norfolk, England, is situated 111 miles from London, on the banks of a small stream, which, rising near Howe in Clavering, falls into the Yare at Hardley Crofs. The church, which is a handsome stone structure, with a fine tower, was erected near the end of the fifteenth century, at the sole expence of sir James Hobart, the attorney-general to king Henry VII., and afterwards chief justice of the common pleas, who was a great benefactor to this town and its vicinity. In the church are several memorials of the Hobart family. In the east window was a piece of stained glass, now removed, representing sir James and his lady, with a sketch of the church, and an appropriate inscription. Loddon was returned, in the year 1800, as containing 166 houses and 799 inhabitants. A market is held on Fridays, and two fairs annually. Blomfield's History, &c. of Norfolk, 11 vols. 8vo.

LODE, a town of the island of Sardinia; 80 miles N. of Cagliari.

LODE, in *Inland Navigation*, signifies a cut or reach of water.

LODE, in *Mining*. This word is derived from the Anglo-Saxon, according to Dr. Pryce, and is used by the Cornish miners to designate any regular vein, whether metallic or not. More commonly, however, it means a metallic vein.

The lodes that are found to contain tin and copper ores, in Cornwall and Devon, have their general direction in a line running nearly east and west; their dip or *underlay* being more commonly to the north; though some which incline to the south have been very productive. Veins which intersect the east and west lodes are called *cross-lodes*, or *cross-courses*, when their direction is nearly at right angles with the others; and *counters*, more generally, when their direction is oblique.

The metallic east and west lodes are traversed or disturbed by the cross-courses, and these interruptions are known by the name of *heaves*, which take place to very different degrees of extent, and vary much in the circumstances under which they are found; so that miners do not agree upon any certain rules for determining the distance or direction of the heave by the accompanying appearances.

Though copper and tin are found but partially in cross-lodes, yet lead has been raised in large quantities from some that have nearly a due north and south course; such as the Beeralstone lead-mines and Wheal Betsy lead-mine in Devon. East and west lodes have sometimes a mixture of lead ores with copper; but this appears to be derived from the intersection of a cross-course, or the effect of a later deposit. Lodes traverse all kinds of rock found in the line of their direction, whether vertically or horizontally. Those worked in Cornwall and Devon are chiefly in *kilas* or *grauwacke* slate; but they are sometimes in granite, and pass not unfrequently from the former into the latter.

The width of veins varies from an inch or two to fifteen or twenty feet; the latter dimension being rare, as the former is unprofitable to follow, unless in the expectation of an enlargement. The more common width, or, as the miners call it, the *size of lodes*, is from two to four feet; and if such a vein as this be fully impregnated with metal, it is

very

very profitable to work, and is called a good *course of ore*. The variations of width take place not only in distinct veins, but in one and the same; which, together with the fluctuations in the nature of their contents, render their produce so uncertain. A large and productive lode often dwindles to a mere *branch*, requiring an experienced eye to distinguish it from the rock through which it passes; and this again expands to a considerable size, filled with deposits of various kinds. The width of lodes seems often to have a relation to the nature of the rock in which they are found; and changes in the latter appear generally to produce changes in the former. Thus, a vein that is large and productive in soft blue killas, will, by passing into harder, become less in size, and barren as to metallic contents. Another lode may be rich in hard ground, but poor and unproductive in that which is of a softer kind; but this is not so frequent as the former case. The deposits of metal are as irregular in the lodes as the widths of them; and so much so, as to render the profits of mining proverbially uncertain. Ore is generally found to occupy certain parts of the veins only, differing constantly in extent, whether the length or depth on the course of the vein be considered, or the portion of its width which is filled up by it. No lode has been found regularly impregnated with metal to any great extent; and therefore, when ore is found, it is in what the miners aptly call *bunches* or *shoots*. The unproductive parts of veins, even in the most profitable mines, generally far exceed in extent the productive parts; but that mine is considered to be rich, which has either frequent or extensive shoots of ore; the great art of the miner, therefore, consists in tracing and working the valuable accumulations of the metals with as little waste of labour and expence on the poorer ground as possible.

Although the bunches of ore have no regular form in their vertical or horizontal extent, yet the tendency to a certain direction or dip in the lode may be observed in each bunch or shoot of ore. These shoots are frequently parallel in the same vein; and where the dip or underlay of the lode is to the north, the shoots of ore may frequently be observed to dip west in the lode. In veins underlaying south, the bunches of ore frequently have their dip to the east: but this is not to be taken as a general rule, as many mines afford exceptions to it; the underlay of the lode and the dip of the bunches of ore being reversed.

These tendencies or inclinations of the deposits of metal in the veins, connected with the situations, dips, and bearings of the veins themselves, seem to offer grounds for argument on the disputed question of the mode in which the metals were deposited; but they have not much, we believe, attracted the notice of mineralogists.

Lodes continue to indefinite lengths, and to unknown depths. It is very difficult to determine whether the end of any regular vein has been found or not; as there are many instances of their having become so small as to be scarcely visible, and yet afterwards, on pursuing them, to have resumed their usual size. When a lode has continued small, either in length or depth, to any considerable extent, it is moreover usually abandoned as unpromising; and thus complete evidence as to this question is not obtained.

Lodes are perfect in the surface of the mountains, as well as in their greater depths; and may be traced uniformly by removing the soil with which the rock is covered. This is done constantly by the miner when he is about to undertake operations upon a newly discovered vein. This process is called *costeining*, or *shedding*. The width of a lode at the surface is no certain indication of its size in depth: as, when large at the surface, they are sometimes found to become

small as they are pursued downwards; and, on the other hand, veins of moderate width at *grafs* have been found, at 40 or 50 fathoms deep, of great size.

The dip or inclination of lodes is seldom uniform. The common *underlay* is from one to four feet in a fathom of depth; but instances occur of a much greater inclination. The lodes that incline much from the perpendicular are not esteemed so promising as those which have a direction more downright; and it is a favourable symptom when a lode, from an oblique direction, is found to turn downwards. On the contrary, where bunches of ore *fail*, or become poor, in sinking on them, it may often be observed that the vein *goes away flat*, as miners express it. Thus it will be understood, that not only are the dips different in separate lodes, but that the same vein frequently varies in this respect. Lodes have been observed to change their underlay, that is, from dipping to the north, to become perpendicular, and even turn to the south. This is not, however, a matter of frequent occurrence.

The underlay of lodes must be ascertained, when it is intended to sink perpendicular shafts to meet them at certain required depths; and from this is determined the distance to be set out north or south from the back of the vein, for commencing such shafts.

Shafts are often sunk *upon* the lodes, and of course these are not perpendicular, but have the same inclination as the veins.

Levels driven from the shafts, are carried on in the substance of the lode, follow its direction, and are the principal means by which discoveries of ore are made and pursued.

The principal methods by which lodes are discovered are the two following: 1. By removing the soil covering the surface of the rock, by which the back of the vein is laid bare, and exposed to view. This may happen accidentally, in the formation of roads, ditches, and so on; or, as is more usual, it may be done for the express purpose of discovery, in consequence of indications of veins being near at hand, such as detached fragments being found, or springs of water impregnated with metal being observed. This process is conducted by sinking trenches, or pits, deep enough to reach the surface of the rock, called by miners the *shelf*; which trenches are called *shedding pits*, or *costeining pits*. The detached fragments, washed from the backs of lodes, are usually called *sheddes*, or *shedde-stones*.

The second mode of discovering veins is by levels, or horizontal cuts, driven under ground, which in their progress through the rock, or, as the miners say, across *the country*, intersect and expose lodes before unknown. Such levels must have a direction across the usual course of the lodes, and are either conducted for the express purpose of finding new veins, or for some other object; and then may occasionally be the means of valuable results of this sort.

Many rich mines have been opened, in consequence of a discovery made by carrying on an adit, or by driving a cross level from a shaft, or from one lode to another known to be parallel to it. The practice of driving adits for the purpose of discovery is more frequent than it used to be. The Tavielock canal has a long tunnel driving through a hill, defined principally for this purpose, and which has already been attended with very great success.

Lodes seldom contain ore near the surface of the ground: it is, therefore, an essential quality in a miner's judgment to decide on the indications presented by them, and to determine the amount of risk which their appearances will warrant on a further trial.

There are niceties in this business which cannot be described,

scribed, but must be seen and studied to be understood, and with which skilful miners are conversant; but the most experienced is liable to have his predictions falsified by the fluctuating nature of these hidden receptacles of various matter.

The indications most depended on, in forming a judgment of the value of a lode, are derived from considering the following circumstances:

1. The nature of the substances contained in the vein.
2. The kind of rock in which it is found.
3. The width and regularity of the vein, considering, at the same time, its direction and dip.
4. The structure of the vein, such as the being open and pervious to water, or, on the contrary, hard and close.

These symptoms may be, on the whole, considered as pertaining to veins containing all kinds of metals, though varying in some in a certain degree: thus a hard close lode may be favourable for tin, though not so for copper or lead.

When a vein is found exhibiting all or most of the appearances which experience has determined to belong to those which are productive, it is called a *kindly lode*, and is generally pursued with vigour, and at an expence proportioned to the prevalence and continuance of the favourable symptoms.

We shall endeavour to consider the principal indications, according to the order above stated, and point out the leading facts to be observed in this important branch of a miner's business.

1. *Of the nature of the substances contained in the vein.*

These substances vary according to the depth to which the lode is opened; those near the surface being generally different from the contents of the vein deeper under ground.

The first thing for which a miner looks is what in Cornwall is called *gossan*. This substance does not appear to have been very accurately described, but is apparently a decomposed mineral of an iron-ochre colour, varying from yellow to brown-red and chocolate-brown. It is of a spongy, cellular texture, of little specific gravity, and is generally soft and friable. It is probably the result of the decomposition of pyrites or mundie, together with quartz, and contains a considerable portion of iron, and not unfrequently a mixture of tin and copper ores. When these latter are present in the combination, it is a most favourable symptom; but even without them, gossan on the back of a lode warrants a trial to a certain extent. It can by no means be asserted, that the most promising gossans have always been followed by ore, on a further pursuit; but perhaps there is hardly an instance of a lode rich in ore, which has not a bunch of *kindly gossan* somewhere on the back.

The next substance, proceeding in depth, upon which reliance may be placed, is *mundie*, including in this name pyrites of all kinds, whether arsenical or sulphuretted, containing iron or copper. Mundie is found at all depths and in all situations in veins: it frequently surrounds bunches of copper ore, and is therefore a favourable symptom, as they are approached; and indicates their decline, when passed through on the other side. It should, however, be recollected, that mundie is very generally found, and therefore it must not be depended on by itself.

The earthy substances, which are esteemed favourable to the existence of valuable metallic ores, are principally quartz, going under the general name of *spar*; a kind of clay called *floukan*; and, what is not very abundant, *fluor*, distinguished by the appellation of *candied spar*.

The first and the chief ingredient in veins, *quartz*, is kindly, when it is in a loose friable form, often crystallized,

and cementing detached fragments of killas and the other substances before enumerated. It is unpromising when in a close amorphous form, and is then termed a *sharp hungry spar*.

The *floukan*, or clay, generally forms a branch or vein on one of the walls of the lode, and seems to be the division between that and the rock containing it.

The decomposition of the adjoining strata seems to have been the origin of this substance, which is called by some foreign writers the *saalbande*.

Besides fluor, on which miners are not well agreed as to its promising aspect, and which is not often found in quantity, are some other minerals, likewise of not very frequent occurrence, but esteemed favourable; such as *prian*, a kind of decomposed quartz, and *peach* or chlorite.

Hitherto we have said nothing of the judgment formed by ores found in a lode; it depends upon the following circumstances:

1. The situation, whether shallow or deep.
2. The mode of deposit, whether slightly sprinkled through the lode, or forming shoots or bunches of large or small extent.
3. The quality of the ore.

Under the first head, most miners agree that, as to copper lodes, rich bunches of ore found near the surface are not to be depended on as shewing that a mine will be very productive; it having often been found that such deposits have been followed by poverty at a greater depth. Tin and lead are found nearer the surface than copper. When a lode is spotted with small quantities of ore, and the other substances are kindly, such as the gossan and spar, the appearance is promising; but when the lode is hard, and in other respects unkindly, then small strings of ore are not to be reckoned on as particularly favourable. After a certain depth, a regular branch, or, as it is called, a *leader* of ore of any width, occupying part of a good-sized vein, and increasing or even fluctuating in size as it is pursued, is on the whole the best symptom, particularly if connected with favourable accompanying substances.

Under the head of quality of the ore as an indication of future prosperity to a mine, it must be remarked that nothing requires to be received with greater caution than promises of success supposed to be derived from the richness of individual specimens. We are speaking now more particularly of copper lodes. Few, we believe, of the most profitable mines produce much ore of the richer varieties, which indeed is seldom found to occupy veins of considerable width: on the contrary, most of the best mines are those which yield ore in large quantities, but poorer in metallic content. This observation has been likewise made on the silver mines of South America, according to the account of Humboldt. Copper ores are found in a greater variety of species near the surface than they are in depth; and therefore the miner's experience only will serve to discriminate perfectly on this point: but we wish to put all who are concerned in mining on their guard against a fallacious hope, too frequently excited by the assay of a stone of ore, which in reality often predicts the very reverse of what it is stated to do by the artful or ignorant.

II. The second indication to be attended to, in estimating the prospect of success on a particular vein, has been stated to be *The kind of rock in which it is found.*

It is unnecessary here to go into a voluminous account of rocks, because the great mines of England, as well as of the world, being found in such mountains as are conjectured to be of very early formation, do not admit the varieties in this respect, which some, who are acquainted only with other

other districts, where probably a later formation has exhibited different phenomena, might conjecture.

Lead-mines, indeed, exist in many parts of England, in various rock, and under various circumstances; but no general rules of mining can be formed from deposits of a metal, which appears to have taken its place at a period comparatively late. Such rules can only be applicable to separate districts, where the circumstances attending the deposits are similar.

There are two general classes of rock which claim the distinction of metalliferous above all others. These are the *killas* of the Cornish miner, or grauwacke or transition slate of Werner; and granitic rocks, including porphyry, gneiss, and other varieties, known in Cornwall by the general name of *grogran*.

Of these the great majority of mines are in *killas*, or grauwacke, not only in Cornwall and Devon, but in Scotland, in the Hartz, in the Saxon Erzgebirge, on the Rhine, in Bohemia, Silesia, Moravia, Salzburg, and other districts important for their mineral products.

Granitic rocks are not so metalliferous as the *killas*, but productive veins are found in them; and, as Dr. Berger has well observed in his account of Devon and Cornwall, in the first volume of the Transactions of the Geological Society, even the *killas* is not a depot of metallic veins to any extent, but near its junction with the granite: and this observation had been made, as he says, by baron Born and Ferber on the mines of the continent.

This fact of most mines being in one prevailing rock, would seem to simplify the exercise of judgment in a miner speculating on the effect of the rock upon the contents of a lode. But though *killas* is so universal, it is far from being all alike: on the contrary, it consists of many varieties. These varieties do not alternate according to certain rules, like the beds of secondary rocks; but exhibit changes in position and extent, more or less frequent, and most uncertain and capricious.

The varieties of *killas*, which are esteemed the most kindly for copper, are the blue and the white, more especially if of a tender, slaty texture. Tin often is found in abundance in harder *killas*, more irregular in its structure, and of a darker colour, indicating the presence of iron. Practice alone can enable men to judge of the shades of difference in these respects, which long experience has pointed out as essential to be attended to: and even then, allowance must be made for exceptions which frequently occur; rules which seem to hold good, when applied to one mine, being often inapplicable to another.

III. The third thing to be considered is *The width and regularity of the vein, and its direction and dip*.

These are important circumstances. If the lode be small, it cannot be expected that abundant deposits of metal can be found; and if it has not the characters belonging to a regular fissure, it is probable that the miner will soon be disappointed, by finding it dwindle to a trifling branch, or split into several insignificant ramifications.

Every large and productive lode is accompanied by other veins running parallel to it, or nearly so, which often fall into the main lode, and generally enrich it by their junction.

These must be carefully attended to, and sought after, as the changes that they produce are often most important, and the quantity of ore which they yield is frequently very great. It has indeed been asserted, that there is hardly a mine working on a single vein only, which has been profitable to any great degree.

The direction of the lode should be carefully ascertained;

because certain ores are only found in veins which have their course in common with others having similar deposits in the district.

Thus the writer of the present article has observed that copper and tin, in Cornwall, must only be expected in lodes running east and west; while lead is raised from such as have a direction at right angles to them, or from north to south.

The more usual dip or underlay, in copper mines particularly, is to the north; but some lodes that underlay to the south have been very productive. In either case, it is no favourable symptom to find the inclination from the perpendicular to be great; and it may be said to be so, if it exceed four feet in the fathom.

When a lode often splits or divides into two or more branches, it is subject to fluctuation in its produce; and these occurrences are important to be noticed with attention, as they afford prognostics as to the future success of working.

IV. The fourth and last head, under which we have arranged the appearances of productive lodes, is that relating to *The structure of the vein, whether open or porous, and thus pervious to water; or, on the other hand, dense and close, and consequently dry*.

All miners agree in this, that water being found to be abundant in a lode is an omen of a very favourable nature; and it is often confidently asserted, that no large returns of ore have been made from dry veins. As far as the experience of the writer of this article goes, it serves to confirm the observation.

Water, indeed, may be found passing freely through cross-courses, and other veins, from which metallic deposits are absent; but then such veins will be found to have all the characters which are adduced as proofs of a later formation, and are therefore easily distinguished from metallic veins.

Large lodes act as natural underdrains, and are channels through which water percolates; so that the rock lying on either side may often be sunk upon with but little interruption from water-until the vein is cut into, and then abundant streams flow out, and would put an end to further labour, if it were not for the aid of proper engines to get rid of it.

The quantity of water will of course be, in some degree, proportioned to the extent of the wide and porous parts of the lode; and, as it is from these parts only that much ore can be expected, the water forms in the first instance a pretty good prognostic.

If, in driving upon the course of a small, close, and unproductive lode, a stream of water be suddenly met with, it indicates the approach to an enlargement in the vein, and is a most favourable symptom; and it is, in point of fact, almost always observed before a good course of ore is seen.

The mines of Devon and Cornwall abound with water in a much greater degree than perhaps any others; and as evidence of this, we may adduce the number of vast steam-engines and overshot water-wheels employed for the sole purpose of draining them. We believe, likewise, that when the quantities of ores raised in this district be compared with those of any other which yield them from *true veins*, they will be found abundant in the same proportion.

Under the head of the internal structure of lodes, may be noticed the cavities, called by the Germans *druses*, and by the Cornish miners *voogs*: these are observed most frequently in large veins, and in such, of course, assist in the passage of water, and may be classed in the same place as a favourable indication. In these *voogs* are found all the varieties of

of crystals; and thus the presence of these in a lode is likewise considered promising, more particularly where observations are made on a vein at no great depth: for as the mine becomes deeper the lode often becomes more compact, and the miner calculates upon finding *solid courses of ore*.

In connection with this part of the subject, the *walls* which enclose the vein are not to be disregarded, when the lode itself is considered, as they should be found to be well determined, smooth, and regular. The rock of which they are formed should be of the hard schist called by miners *espel*; and if penetrated with traces of ore, it may be considered as a symptom of large deposits. On each side of the walls, which usually differ somewhat from the adjoining rock, as if altered by the presence of the vein, the strata may generally be observed to be twisted or bent downwards, in a slight degree towards the lode, which is in general considered to be more the case near large veins than near those which are smaller.

Having now detailed the principal characteristics of lodes, as important to the practical miner, described the modes of discovering them, and the symptoms by which a judgment is formed of their contents, as far as relates to working them for the metals; we leave the consideration of them, in a geological point of view, for the article *VEIN*. The operations of working upon them will be described under the head of *MINING*, and under that of *ORE*.

LODE, in *Rural Economy*, a provincial term applied to signify ford, in some districts.

LODER, in *Geography*, a town of Bavaria; 25 miles S. of Augsburg.

LODESAN, a country of Italy, in the Milanese, bounded north and west by the duchy of Milan, east by the Cremasco and the Cremonese, south by the Piacentia and Pavese; and now forming the department of the Adda. It is populous and fertile, though small; and particularly celebrated for its cheese, of which, it is said, the inhabitants annually export to the amount of 70,000*l*.; the number of cows kept here being reckoned at 30,000. The capital is Lodi.

LODESE, or *GAMLA Loder*, a town of Sweden, in West Gothland, which suffered so much from fire in the thirteenth and fourteenth centuries, that the inhabitants removed to New Lodefe, or Nydolefe.

LODESMAN, or *LOCMAN*, a pilot established for conducting vessels in and out of harbours, or up and down navigable rivers. See *PILOT*.

LODEVE, in *Geography*, a town of France, and principal place of a district, in the department of Hérault, and, before the revolution, the see of a bishop; 24 miles W. of Montpellier. The place contains 7843, and the canton 13,959 inhabitants, on a territory of 307½ kilometres, in 10 communes. N. lat. 43° 44'. E. long. 3° 24'.

LODGMET, in *Military Affairs*, sometimes denotes an encampment made by an army.

LODGMET is more frequently used for a work cast up by the besiegers, during their approaches, in some dangerous post, which they have gained, and where it is absolutely necessary to secure themselves against the enemy's fire; as in a covert-way, in a breach, the bottom of a moat, or any other part gained from the besieged.

Lodgments are made by casting up earth, or by gabions, or palisades, woolpacks, fascines, mantelets, or any thing capable of covering soldiers in the place they have gained, and are determined to keep.

LODI, *LA*, in *Biography*, a young female singer, in the service of the elector of Bavaria, at Munich in 1772, and now, if she lives, an old one; so that a few remarks upon

her slight imperfections can do her neither good nor harm, but may probably stimulate a wish of purification of voice in others. We thought that, in general, the tone of the Lodi's voice was clear and brilliant, and her manner of singing and acting elegant and graceful; yet thought, if there was any little defect in her voice, it was occasioned by a slight obstruction in the throat, particularly in sustaining low notes. These were our thoughts the first time we heard her. The second time, we were more pleased with her performance than the first; yet still imagined that her voice wanted a little more room in its passage. The third time we heard her in her best character, in the performance of which the still gave us more pleasure; but yet we could not get rid of our former remarks on the conduct of her voice in sustaining certain low and long notes.

These remarks, made on the Lodi 52 years ago, might, with respect to voice, be fairly applied to Mrs. Hindmarsh in 1804.

LODI, in *Geography*, a city of Italy, formerly the chief town of Lodetan, now the capital of the department of Adda, built by the emperor Frederick Barbarossa, on an eminence, in a plain watered by the river Adda. It is the see of a bishop, and contains, besides the cathedral, two collegiate and seven parish churches, and 26 convents. This is a place of little trade, its chief commodities being cheese (see *LODESAN*) and a beautiful kind of earthen ware resembling china. It is well built, and surrounded with walls, about three miles from the ancient town of the same name, called also "Laus Pompeii." The number of inhabitants is estimated at about 12,000. On the 11th of May 1796, the town was taken by the troops of the French republic, under the command of Bonaparte, Massena, and Angereau; after the passage of the bridge had been contested by 10,000 Austrians, and 30 pieces of artillery. The Austrians lost in killed, wounded, and prisoners, between two and three thousand men; 18 miles S.E. of Milan. N. lat. 45° 21'. E. long. 9° 30'.

LODOMIRIA, a territory of Poland, which, together with Galicia (which see), was ceded to the house of Austria in the late partition of Poland, A.D. 1772, and is now incorporated under this appellation with the Austrian dominions. The number of inhabitants in this ceded country amounted, in 1776, to 2,580,796. Hoeck computes Eastern Galicia and Lodomiria at 2,797,119, and Western Galicia at 1,106,178. The mountainous parts of Galicia and Lodomiria afford fine pastures; the plains are mostly sandy, but abound in forests, and are fertile in corn. The principal articles of traffic are cattle, hides, wax, and honey; and these countries contain mines of copper, lead, iron, and salt.

LODRONE, a town of Italy, in the Trentin, on the borders of the Bressan, near a small lake, called the "lake of Idro;" 25 miles S.W. of Trent.

LODOSA, a town of Spain, in Navarre, on the Ebro; 17 miles E. of Estella.

LODYPOUR, a town of Hindoostan, in Bahar; 18 miles S. of Patna.

LODZIEZE, a town of Lithuania, in the palatinate of Troki; 48 miles N.N.W. of Grodno.

LOE, a town of Norway; 48 miles N.E. of Drontheim.

LOE, in *Rural Economy*, a term used to signify a little round hill, or a heap of stones.

LOEBEGUN, or *LOBOCHIN*, a town of the duchy of Magdeburg; 44 miles S. of Magdeburg.

LOEBOE, or *LOEHOB*, a kingdom of Celebes, which was the most powerful and extensive of all the states of this

island,

ifland, before those of Macassar and Boni attained their subsequent celebrity. It stretches at present from Palopa, the capital of the country, to Larompo, having an extent of about 20 leagues along the western shore of the bay of Boni, and from the other side of the city, over the whole of the S.E. part of Celebes, between Buguefs-bay and the E. coast of the island, as far as the Alforse will suffer them inland; to the W. it is bounded by Wadjo, and to the N. by Taradja. The land is fertile in paddee; it yields likewise good iron, and much gold is found in the rivers. The first king mentioned in the records of the Dutch company, and called "Crain Haroo," was subdued by the arms of the company, at the same time with the Macassars at Bouton. For an account of its dissolute queen, see TANERE.

LOEFFLINGIA, in *Botany*, named by Linnæus in honour of his friend and favourite pupil Peter Loeffling, a Swede, who was born in the year 1729, in the province of Güttrikeland. He began to study medicine at the age of 16, and from his proficiency in the science of Natural History he afterwards obtained, through the recommendation of Linnæus, the appointment of botanist to the king of Spain, in which capacity he explored the botanical treasures of South America, where he died Feb. 22, 1756. His name frequently occurs in the writings of his preceptor, who published at Stockholm, in 1758, a collection of Loeffling's letters, and the Latin descriptions of Spanish and American plants which he left behind him, with a biographical preface of his own, in Swedish. A German translation of this volume, by Kölpin, appeared at Berlin in 1766. The inaugural dissertation of Loeffling on "the buds of trees" is printed in the *Amoenitates Academicæ*, v. 2. 182.—Linn. Gen. 24. Schreb. 33. Willd. Sp. Pl. v. 1. 191. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 79. Juss. 299. Lamarck Illustr. t. 29. Gaertn. t. 129.—Class and order, *Triandria Monogynia*. Nat. Ord. *Caryophylleæ*, Linn. *Caryophyllea*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five, erect, lanceolate leaves, marked on each side at the base with a small tooth, sharp-pointed, permanent. *Cor.* Petals five, very small, oblong-ovate, closed together in the form of a globe. *Stam.* Filaments three, the length of the corolla; anthers roundish, twin. *Pist.* Germen superior, ovate, triangular; style thread-shaped, a little dilated upwards; stigma rather obtuse. *Peric.* Capsule ovate, nearly triangular, of one cell and three valves. *Seeds* numerous, ovate-oblong.

Eff. Ch. Calyx of five leaves. Corolla of five petals, very small. Capsule of one cell, and three valves.

1. *L. hispanicum*. Spanish Loefflingia. Linn. Sp. Pl. 50. Loeffl. It. 113. t. 1. f. 2. Cavan. Ic. v. 1. 64. t. 94.—Leaves awl-shaped, sharp-pointed. Flowers axillary, sessile.—Found on open hills in the neighbourhood of Madrid, and other parts of Spain, flowering in June.—*Root* annual, zig-zag, smooth. *Stems* procumbent, sometimes a little ascending, jointed, round, slightly pubescent, viscid, about two inches long. *Leaves* in pairs at the joints of the stems, sometimes three or four together. *Flowers* nearly white. Linnæus remarks, that this species approaches in habit to *Scleranthus* or *Herniaria*.

2. *L. indica*. Indian Loefflingia. Willd. n. 2. Retz. Obf. fasc. 4. 8. (*Pharnaceum depressum*; Linn. Mant. 562.)—Leaves oblong. Flowers axillary, cymose. A native of rice fields and dried pools in the East Indies, where it abounds, according to König, in April and May.—*Root* very long and branching. *Stems* numerous, prostrate, about a span in length, pubescent. *Leaves* two, four or more together at the joints, almost sessile. *Stipulas* solitary, small,

membranaceous. *Flowers* nearly sessile, cinereous, with a trifid style. Linnæus, who places this species in *Pharnaceum*, says that it resembles a *Mollugo*, and that it puts forth its flowers only in fine weather. Retz and Willdenow properly make it a *Loefflingia*, of which authors, the former observes, that *L. indica* has dark-green and keeled calyx-leaves with a broad scaly margin. The *corolla* is purple, smaller than the *calyx*. The *capsule* of one cell, with many seeds.

LOEILLET, JOHN, in *Biography*, a relation of John Baptist Locillet of Ghent, the famous master on the common flute, and voluminous composer for that instrument. John the younger was a celebrated harpsichord master, and performer in the opera band in London, while Corbet was the leader.

Having a large room in the house which he occupied in Hart-street, Covent Garden, he established a weekly concert there, which was frequented chiefly by gentlemen performers, who rewarded him liberally for conducting it. Corelli's concertos were first performed in England at this concert, where Mr. Needler, at the head of dilettanti players on the violin, was the leader.

Locillet was not only an excellent teacher of the harpsichord, but a good composer for that instrument, and a minut in his lessons, in the key of A minor, which was in great favour with the ladies of that time, from the vulgar pronunciation of Locillet's name, was long supposed to have been composed by John Baptist Lully, whose name was prefixed to it in many printed books, nor was the mistake ever publicly cleared up.

Locillet died about the year 1728, after accumulating, by industry and economy, a fortune of 16,000*l.* The works which he published, though numerous, are now only to be traced in Walf's old catalogues.

LOENEN, in *Geography*, a town of Holland; 10 miles S.W. of Naerden.

LOESDRECHT, a town of Holland; eight miles S. of Naerden.

LOESLIA, in *Botany*, received its name from Linnæus, in honour of John Loefel, Professor of Medicine at Königsberg in Prussia, who was born in the year 1607, and died in 1655. By the direction of our author's will, his son edited a catalogue of the native plants of Prussia, which is by no means a despicable work. It abounds with several curious notes, and contains many rare plants which till then were unknown as natives of Prussia. He had also prepared several excellent plates, and these, together with his manuscripts, partly by the wish of his son to perpetuate his father's fame, and partly by royal authority, were afterwards committed to the charge of his successor, Professor John Gottsched, who compiled from them the *Flora Prussica*, seu *Plantæ in Regno Prussie sponte nascentes*, which was published in quarto in 1743. The book is scarce, but is frequently cited for the plates.—Linn. Gen. 317. Royen. L. Bat. 299. Schreb. 415. Willd. Sp. Pl. v. 3. 323. Mart. Mill. Dict. v. 3. Juss. 135. Lamarck Illustr. t. 527. Gaertn. t. 62. (Royenia; Hoult MSS.)—Class and order, *Didymia Angiospermia*. Nat. Ord. *Corniculæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, four-cleft, acute, short, permanent. *Cor.* of one petal, unequal; tube the length of the calyx; limb in five, ovate-lanceolate, equal segments, all deflexed towards the lower side. *Stam.* Filaments four, the length of the corolla, two of them shorter, all opposite to the segments of the petal and reflexed, in a contrary direction to the corolla; anthers simple. *Pist.* Germen superior, ovate; style simple, placed like the stamens; stigma thickish. *Peric.* Capsule ovate,

of three cells. *Seeds* solitary or two together, slightly angulated.

Obf. Gärtner remarks, that he found five ftamens in all the flowers of this genus which he had examined, though one of them was constantly fhorter than the reft. Hence it has been fuggelted that *Loefelia* fhould be referred to *Pentandria*.

Efl. Ch. Calyx four-cleft. Corolla with its fegments all leaning one way. Stamens oppofite to the petal. Capfule of three celis.

1. *L. cilata*. Fringed Loefelia. Linn. Sp. Pl. 875. Gärtn. t. 62. f. 3.—Found by Dr. Houftoun at Vera Cruz in South America.—*Stem* erect, flightly quadrangular. *Leaves* oppofite, lanceolate-ovate, fharply ferrated. *Flowers* yellow, forming a head at the ends of the branches, accompanied by imbricated, ovate, fringed *bractæes*.

This genus is fully defcribed by Gärtner, who moft probably muft have made his defcription from the fpecimen fent by Dr. Houftoun to Mr. Miller's collection, now in the poffeffion of the right honourable fir Jofeph Banks. Linnæus had it not in his own herbarium, but appears to have feen it in the hands of Adrian Van Royen during his ftay at Leyden. Hence it found admiffion into the appendix of the firft edition of his *Genera Plantarum*, p. 348.

LOEVESTEIN, or LOUVESTEIN, in *Geography*, a fortress of Holland, where Grotius was confined, and whence he was delivered by a stratagem of his wife. See the article GROTIUS.

LOEVI, in *Ancient Geography*, a people of Italy, whose cantonment lay between the rivers Sefilis and Ticinus, now the Selia and Tefino.

LOFANGER, in *Geography*, a town of Sweden, in Weft Bothnia; 40 miles N.N.E. of Umea.

LOFANGO, one of the fmaller Friendly iflands; five miles E.S.E. of Neeneeva.

LOFEEREN, a clufter of fmall iflands in the North fea, near the coaft of Norway. N. lat. 68°.

LOFFALO, a fmall ifland in the gulf of Finland. N. lat. 60° 2'. E. long. 46° 3'.

LOFFINGEN, a town of Germany, in the lordfhip of Furftenberg, having a medicinal bath; fix miles W. of Furftenberg.

LOFFODEN ISLANDS, a clufter of iflands off the Norwegian coaft, in N. lat. 67° to 68°. Thefe iflands are numerous and extenfive, and noted for the whirlpool of Maelstrom. They have excellent fisheries, and the palturage fuffices for a great number of fheep.

LOFSTA, a town of Sweden, in Smaland; 70 miles N. of Calmar.—Alfo, a town of Sweden, in the province of Upland, in which are a hammer-mill, eight forges, and a fmelting furnace; 40 miles N. of Upfal.

LOFTUS HEIGHTS, the barrier-port in the S.W. corner of the United States, on the E. fide of the Miffiffippi, in Adams county. Miffiffippi territory, about 40 miles below Natchez. The plan of the works here contructed presents the handfomeft military object in the United States.

LOFVESTA, a fea-port town of Sweden, in the province of Schonen; 25 miles S. of Chriftianftadt.

LOG, is the *Jewifh Antiquities*, a meafure which held a quarter of a cab, and confequently five-fixths of a pint. There is mention of a log, 2 Kings, vi. 25. under the name of a *fourth part of a cab*. But in Leviticus the word log is often met with, and fignifies that meafure of oil, which lepers were to offer at the temple after they were cured of any difeafe.

Dr. Arbuthnot fays, that the log was a meafure of liquids, the feventy-fecond part of the bath or ephah, and

twelfth part of the hin, according to all the accounts of the Jewifh writers.

LOG, a fea-term, fignifying a fmall piece of timber of a triangular, fectoral, or quadrantal figure, on board a fhip, generally about a quarter of an inch thick, and five or fix inches from the angular point to the circumference. It is balanced by a thin plate of lead, nailed upon the arch, or circular fide, fo as to fwim perpendicularly in the water, with about two-thirds immerfed under the furface.

LOG-line, a little cord, or line, about a hundred and fifty fathoms long, faftened to the log, by means of two legs, one of which paffes through a hole at the corner, and is knotted on the oppofite fide, while the other leg is attached to the arch by a pin fixed into another hole, fo as to draw out occasionally. By thefe legs the log is hung in equilibrio; and the line thus annexed to it is wound round a reel fixed for that purpofe in the gallery of the fhip.

This line, from the diftance of about ten, twelve, or fifteen fathoms off the log, has certain knots or divifions, which ought to be at leaft fifty feet from each other; though it was the common practice at fea, not to have them above forty-two feet afunder.

The length of each knot ought to be the fame part of a fea-mile as half a minute is of an hour; and admitting the meafurement of Mr. Norwood, who makes a degree on a great circle of the earth to contain 367,200 Englifh feet, or about 69½ Englifh ftatute miles; and, therefore, $\frac{1}{720}$ of it, or a nautical mile, will be 6120 feet; $\frac{1}{720}$ th of 6120, or 51 feet, fhould be the length of each knot. But becaufe it is fafer to have the reckoning rather before the fhip than after it, therefore fifty feet may be taken as the proper length of each knot. The knots are fometimes made to confift only of forty-two feet each, even in the prefent practice; and this method of dividing the log-line was founded on the fuppofition that fixty miles, each of 5000 Englifh feet, made a degree; for $\frac{1}{720}$ th of 5000 is 41½, or, in round numbers, 42 feet. Mariners, rather than quit the old way, though known to be erroneous, ufe glaffes for half minute ones, that run but 24 or 25 feconds. They have alfo ufed a line of 45 feet to 30 feconds, or a glafs of 28 feconds to 42 feet. When this is the cafe, the diftance between the knots fhould be corrected by the following proportion: as 30 is to 50, fo is the number of feconds of the glafs to the diftance between the knots upon the line. The heat or moifture of the weather has often a confiderable effect upon the glafs, fo as to make it run flower or fafter; it fhould, therefore, be frequently tried by the pendulum in the following manner. On a round nail hang a ftring that has a mufket-ball fixed to one end, carefully meafuring between the centre of the ball and the ftring's loop over the peg 39½ inches, being the length of a fecond pendulum; then fwing it, and count one for every time it paffes under the peg, beginning at the fecond time it paffes, and the number of fwings made during the time the glafs is running out, fhews the feconds it contains. The line alfo is liable to relax and fhink, and fhould, therefore, be occasionally meafured.

The ufe of the log and line is, to keep account, and make an estimate of the fhip's way, or diftance run; which is done by obferving the length of line unwound in half a minute's time, told by a half-minute glafs: for fo many knots as run out in that time, fo many miles the fhip fails in an hour. Thus, if there be four knots veered out in half a minute, the fhip is computed to run four miles an hour.

The author of this device for meafuring the fhip's way is not known; and no mention of it occurs till the year 1607, in an Eaft India voyage, publifhed by Purchas: but from that time its name occurs in other voyages among his col-

lections: and henceforward it became famous, being taken notice of both by our own authors, and by foreigners; as by Gunter in 1623; Snellius, in 1624; Metius, in 1631; Oughtred, in 1633; Herigone, in 1634; Saltonstall, in 1636; Norwood, in 1637; Fournier, in 1643; and almost by all the succeeding writers on navigation of every country. See *Marine SURVEYOR*.

Log, to heave the, as they call it, they throw it into the water, on the lee-side, letting it run, till it comes without the eddy of the ship's wake; then one, holding a half-minute glass, turns it up just as the first knot, or the mark from which the knots begin to be reckoned, turns off the reel, or passes over the stern. As soon as the glass is out, the reel is stopped, and the knots run off are told, and their parts estimated.

It is usual to heave the log once every hour in ships of war and East Indiamen; and in all other vessels, once in two hours; and if at any time of the watch the wind has increased or abated at the intervals, so as to affect the ship's velocity, the officer generally makes a suitable allowance for it at the close of the watch.

The log is a very precarious way of computing, and must always be corrected by experience and good sense; there being a great deal of uncertainty in the yawing of the ship going with the wind ast, or upon the quarter, in the heaving of it, by its coming home, or being drawn after the ship, on account of the friction of the reel, and lightness of the log, in the course of the current, and in the strength of the wind, which seldom keeps the same tenor for two hours together; which is the interval between the times of using the log, in short voyages, though in longer ones they heave it every hour. Yet is this a much more exact way of computing than any other in use; much preferable certainly to that of the Spaniards and Portuguese, who guessed at the ship's way, by the running of the froth or water by the ship's side; or to that of the Dutch, who used to heave a chip overboard, and to number the paces they walk on the deck, while the chip swims between any two marks, or bulk-heads on the side.

The above-mentioned errors, and particularly the log's being subject to drive with the motion which the water may have at its surface, whereas the experiment requires it to be fixed in the place where it is when the mark commencing the knots goes off the reel, have been considered by writers, and many methods have been proposed to remove, or at least to lessen them. The late M. Bouguer proposed a method, which has been thought deserving of particular attention, in the *Mém. Acad. Sc.* 1747; afterwards in his *Treatise on Navigation*, published at Paris in 1753, and since reprinted in 1760, by the Abbé de la Caille. For this purpose, take for the log a conical piece of wood, which fix to the log-line passed through or along its axis, at about forty, fifty, or sixty, or more feet, from one end; and to this end fix the diver, which is a body formed of two equal square pieces of tin, or of thin iron plate, fixed at right angles to one another along their diagonals; and its size so fitted to that of the cone, that the whole may float. A cone of three inches diameter in the base, and of six inches in the slant height, is proposed by M. Bouguer to suit a diver made of plates about $9\frac{3}{4}$ inches square; the intersection of the diagonals is joined to the log-line, and the loop and peg fixed as in the common log. However, it has been found, that no kind of wood used in British dock-yards, when formed into a cone of the above dimensions, will float a diver made of stout tin plates, one side of the square being $9\frac{3}{4}$ inches. Such a diver weighing $1\frac{1}{2}$ lb. avoirdupois, required to float it, a cone of five inches diameter, and twelve

inches on the slant side, so as the point of the cone, which was made of light fir, should just appear above the water. Now supposing one side of such a square tin diver to be about ten inches, and made of plates only two-thirds of the thickness of the former. Such a diver would weigh, with its folder, about twenty ounces, and can be floated by a light fir cone of four inches diameter in the base, and ten inches in the slant height or length; and such a compound log might, perhaps, be found on trial to be affected by about as much again as that proposed by M. Bouguer, and consequently the difference between the numbers given by the common log and compound log, must be augmented by two-thirds of itself, for the necessary correction, as below. When the compound log of Bouguer, above described, is hove overboard, the diver will sink too deep to be much affected by the current or motion of the water at the surface; and the log will thereby keep more steadily in the place where it first fell; and consequently, the knots run off the reel will shew more accurately the ship's rate of sailing. As the common log is affected by the whole motion of the current, so this compound log will feel only a part thereof, viz. such a part nearly as the resistance of the cone is of the resistance of the diver: then the resistances of the above cone and diver are about as 1 to 5; and consequently this log will drive but one-fifth part of what the common log would do; and so the ship's true run will be affected by one-fifth part only of the motion of the waters. To obtain the true rate of sailing, it will be proper to heave alternately hour and hour, the common log, and this compound log; then the difference of their knots run off, augmented by its one-fourth part, is the correction; which applied to the knots of the common log, will give the ship's true rate of sailing, at the middle time between the hours when these logs were hove. The correction is additive, when the compound log's run is the greatest, otherwise it is subtractive. To find the course made good: increase the observed angle between the log-lines by one-fourth part; and this gives the correction to be applied to the apparent course, or the opposite of that shewn by the common log; the correction is to be applied to the $\left\{ \begin{smallmatrix} \text{right} \\ \text{left} \end{smallmatrix} \right\}$ of the apparent course, when the bearing of the common log is to the $\left\{ \begin{smallmatrix} \text{left} \\ \text{right} \end{smallmatrix} \right\}$ of the compound log. Or thus: the lengths run off both logs, together with their bearings, being known; in a card or compass apply the knots run off, taken from a scale of equal parts along their respective bearings, from the centre; join the ends, and in this line produced, on the side next the compound log's length, take one-fourth of the interval; then a line drawn from the end, thus produced, to the centre of the card, will shew the true course and distance made good. When a current, such as a tide, runs to any depth, the velocity of that current may be much better ascertained by the compound log than by the common one, provided the diver does not descend lower than the run of the current; for as those ships which are deepest immersed, drive fastest with the tide; so the diver, by being acted on below, as well as the log on the surface, their joint motion will give the total effect to the current's motion better than what could be derived from the motion at the surface only. Also by such a compound log, the depth to which any current runs, may be easily tried. Robertson's Nav. book ix. § 1.

We have an account in the *Voyage to the North Pole*, p. 97, of two other logs, which were tried by captain Phipps: one invented by Mr. Russel, the other by Foxon; both constructed upon this principle, that a spiral, in proceeding

ceeding its own length in the direction of its axis through a refilling medium, makes one revolution round the axis; if, therefore, the revolutions of the spiral are registered, the number of times it has gone its own length through the water will be known. In both these the motion of the spiral in the water is communicated to the clock-work within-board, by means of a small line, fastened at one end of the spiral, which tows it after the ship, and at the other to a spindle, which sets the clock-work in motion. That invented by Mr. Ruffel has a half spiral of two threads, made of copper, and a small dial with clock-work, to register the number of turns of the spiral. The other log has a whole spiral of wood with one thread, and a larger piece of clock-work, with three dials, two of them to mark the distance, and the other divided into knots and fathoms, to shew the rate by the half-minute glass for the convenience of comparing it with the log. This kind of log will have the advantage of every other in smooth water and moderate weather; and it will be useful in finding the trim of the ship when alone, in surveying a coast in a single ship, or in measuring distances in a boat between headlands and shoals; but it is subject to other inconveniences, which will not render it a proper substitute for the common log. See Phil. Trans. vol. xlviii. p. 532.

Log-board is a table divided into four or five columns, whereon are marked the reckonings of every day; from whence they are entered into the log-book or traverse-book, whence it may be transcribed into the journals, and how much the ship gains in her course be estimated daily. In the first column of the log-board, is entered the hour of the day, from the noon of one day to the noon of the next; in the second and third, the number of knots and fathoms the ship is found to run per hour, set against the hours when the log was hove: in the fourth, the courses which the ship steers; and in the fifth, or right-hand column, the winds, the alterations of the sails, the business doing aboard, observations made of the weather, variations of the compass, &c. See JOURNAL.

Log-book, at sea, a book ruled and columned like the log-board. It is used by some to enter the log-board's account in every day at noon, with the observations then made; and from hence it is corrected and entered into the journals. (See JOURNAL.) The intermediate divisions or watches of the log-book, containing four hours each, are usually signed by the commanding officer in ships of war, or East Indiamen.

LOGAN, in *Geography*, a county of America, in the state of Kentucky, containing 4870 inhabitants, besides 730 slaves.

LOGANIA, in *Botany*, so denominated by Mr. R. Brown, after Mr. James Logan, President of the Council, and Chief Justice of the Province of Pennsylvania, author of a small Latin tract in support of the Linnæan doctrine of the generation of plants, published at Leyden, in 1739, and republished, we believe by Dr. Fothergill, at London, in 1747, with an English translation. Brown Prodr. Nov. Holl. v. i. 454. (Euosma; Andr. Repof. v. 8. 520.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Geniana*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five deep equal segments, permanent. *Cor.* of one petal, somewhat bell-shaped, rather hairy in the throat; limb in five deep, equal, roundish segments. *Stam.* Filaments five, equal, inserted into some part of the tube, shorter than the limb; anthers small, roundish. *Pist.* Germen superior, ovate, with a groove at each side; style short, thick, permanent; stigma capitate, somewhat club-shaped. *Peric.* Capsule ovate,

with a furrow at each side, separating into two parts, each of one cell and two valves, with a longitudinal triangular receptacle to each cell. *Seeds* numerous, roundish, peltate, rough.

Eff. Ch. Calyx in five deep segments. Corolla somewhat bell-shaped, five-cleft, hairy in the throat. Stamens shorter than the limb. Stigma capitate. Capsule superior, with two furrows, four valves, two cells, and a receptacle to each. Seeds peltate.

This New-Holland genus consists of either shrubs or herbs, with opposite entire leaves, generally attended by stipulas, which are either united into a small intrafoliaceous sheath, or distinct; in the latter case, within the insertion of the leaves or at their sides; sometimes there are no stipulas. Flowers either terminal or axillary, opposite in corymbs or clusters, sometimes solitary. Corolla white, sometimes veined. Albumen fleshy. Mr. Brown indicates its near affinity to *Geniostoma*, see that article, and thence to the order of *Apocinee*, and to *Ulleria*, one of the *Rubiaceae*. He defines eleven species, eight of which are shrubs, with an obtuse calyx, and the stamens within the tube; the rest are herbaceous, or but slightly shrubby, with an acute calyx, and somewhat prominent stamens. Of the eight first-mentioned species, five have the stipulas united into a sheath or ring within the insertion of the leaves. These are called true *Logania*. A specimen of them is

L. latifolia. Brown n. 2. (Exacum vaginale; Labill. Nov. Holl. v. 1. 37. t. 51.)—Leaves obovate, rather pointed at each end. Flowers corymbose. Young branches smooth. Stem erect.—Native of the southern part of New Holland. The stem is shrubby, about a yard high, with upright, square, smooth, leafy branches. Leaves opposite, scarcely stalked, coriaceous, broadly obovate, above two inches long, entire, acute, tapering at the base, and united by means of the short, tubular, intrafoliaceous stipula. Flowers numerous, in terminal and axillary, smooth, repeatedly three-forked, corymbose panicles, with a pair of acute bractees at each subdivision. It is remarkable that Labillardiere says nothing of their colour, neither does he here, or perhaps in any part of his work, seem to have made any notes on the spot, but merely to have described the dried specimens after his return.

The three others have either setaceous, lateral, distinct stipulas, or none at all. These answer to the genus *Euosma* of Andrews.

L. floribunda. Brown n. 6. (Euosma albidiflora; Andr. Repof. t. 520.)—Leaves lanceolate, tapering at each end, smooth. Stipulas lateral, bristle-shaped. Clusters axillary, compound, shorter than the leaves; with downy flower-stalks.—Sent originally by Dr. White, from Port Jackson. Mr. Andrews had it in flower from the fine collection of the Marquis of Blandford, at White Knights, where it was trained against a south wall in the open air, and in April was covered with a profusion of white blossoms, which had the scent of hawthorn. The stem of this plant was about four feet high, shrubby. Branches wand-like, opposite, square, smooth, leafy, reddish. Leaves snow-like, tapering much at each end, near two inches long; smooth, shining and dark green above; whitish, opaque and obscurely dotted beneath. Clusters compound, axillary, shorter than the leaves. Flowers somewhat like lily of the valley, but only half as large. Capsules rugose.

The three last species of this genus, which have, as before mentioned, an acute calyx, and stamens inserted into the throat of the corolla, have received from Mr. Brown a sort of provisional generic name, *Stemandra*, expressive of this last character; so that if any person chooses to separate them from

from *Logania*, he may not be at a loss what to call them. These are

L. serpyllifolia. Br. n. 9.—“Somewhat shrubby. Leaves ovate. Stipulas within the footstalks, fringed like the calyx. Flowers terminal, somewhat corymbose.”—Gathered by Mr. Brown in the south part of New Holland.

L. pusilla. Br. n. 10.—“Herbaceous. Leaves elliptical. Stipulas triangular, within the footstalks. Flowers axillary, solitary.”—Native of Port Jackson.

L. campanulata. Br. n. 11.—“Herbaceous. Leaves linear, without stipulas. Flowers terminal. Flower-stalks and calyx downy.”—From the south part of New Holland.

LOGARITHMIC, ATMOSPHERICAL, is a curve (Plate XI. *Analysis*, fig. 2.) described in the following manner: let the point C represent the centre of the earth, CA the earth's semidiameter, and AB any height above the surface; at A, place a right line AD, of any finite length, at right angles with AC. In the right line AC, towards C, take A β such, that CA may be to A β in the proportion of CB to BA. In a right line drawn through β , at right angles with AC, take βE , of such length, as to be to AD in the proportion of the density of the air at B to the density at A, the earth's surface. The curve, which the point E always touches, is a logarithmic, of which AC is the asymptote; and is called by Dr. Horsley the atmospherical logarithmic.

Imagine this curve described, and take another height Ab, and take $A\epsilon = \frac{CA \times Ab}{Cb}$, and draw $\epsilon\epsilon$ parallel to

βE , meeting the curve in ϵ . Then $\beta\epsilon$ is the logarithm of the ratio of βE to $\epsilon\epsilon$, or of the density at B to the density at b . But if the greater of the two heights, AB and Ab, bear but a very small proportion to the semidiameter of the earth, their difference Bb will be very nearly equal to $\epsilon\epsilon$.

For, because CB : BA = CA : A β by construction. Therefore, by conversion, CB : CA = CA : C β . In like manner, and by inversion, CA : Cb = C ϵ : CA, by equidistance perturbate, CB : Cb = C ϵ : C β , and converting, CB : Bb = C ϵ : $\epsilon\beta$, by permutation, Bb : $\beta\epsilon$ = CB : C ϵ .

But when AB is infinitely diminished, CB = CA ultimately. Also Ab being infinitely diminished, C ϵ = CA ultimately. Therefore CB = C ϵ ultimately, and Bb = $\beta\epsilon$ ultimately. Q. E. D.

Now AB and Ab will always be so small, with respect to CA, if B and b be supposed to represent any accessible places, that CB, C ϵ , and Bb, $\beta\epsilon$, may always, in this case, be considered as in their ultimate proportion of equality.

It is still therefore to be admitted, as a principle, in practice, that the difference of elevation of any two places is as the difference of the tabular logarithms of the heights of the quicksilver in the barometer at the same time at both places; that is, it is the logarithm of the ratio of those heights in some system of logarithms. And the heights of the quicksilver being given by observation, the difference of elevation will be known, if that particular system can be determined; that is, if the modulus of the system, or the length of the subtangent of the curve DE ϵ of that system, can be ascertained, in some known measure, as English fathoms, or Paris toises.

The easiest method of doing this, that theory suggests, is to compare barometers at two stations, suppose B and b, each of a known elevation AB and Ab, above the level of

the sea. For the logarithms of any given ratio, in different systems, are proportional to the subtangents; and the difference of elevation Bb, diminished in the proportion of CB, (the distance of the higher station from the earth's centre,) to C ϵ , (a third proportional to Cb, the distance of the lower station from the earth's centre, and CA, the earth's semidiameter,) is the logarithm of the ratio of the density at B, to the density at β , (that is, of the columns of quicksilver sustained in the barometer at B and b,) in the atmospherical system. Therefore, as the difference of the tabular logarithms of these columns, to the subtangent of the tabular system, so should Bb, diminished as hath been said, (that is, so should $\beta\epsilon$), be to the subtangent of the atmospherical logarithmic. The utmost height to which we can ascend, above the level of the sea, is so small, that the reduction of Bb may, even in this investigation, always be neglected. For, if AB were four English miles, which exceeds the greatest accessible heights, even of the Peruvian mountains, and A ϵ three, $\beta\epsilon$ would be scarce one part in 500 less than Bb. So that, by comparing barometers at different elevations, within a mile above the level of the sea, the subtangent of the atmospherical curve might be determined, as it should seem, without sensible error, by taking simply the difference of elevation, without reduction, for the logarithm of the ratio of the observed height of the quicksilver in the atmospherical system.

The subtangent is different in length at different times; though M. de Luc has shewn, that it is constant in a given temperature; so that if the temperature of the air is + 16 $\frac{1}{4}$ of his scale, the difference of the tabular logarithms of the heights of the quicksilver in the barometer, gives the difference of elevation in 10000ths of a Paris toise; whence the number, which is the modulus of Briggs's system, expresses the length of the subtangent of the atmospherical curve, such as it is in that temperature, in 10000ths of a Paris toise, Phil. Trans. vol. lxiv. part i. p. 231, &c.

LOGARITHMIC, or LOGISTIC Curve, is a curve which obtained its name from its properties and uses in explaining and constructing logarithms; because its ordinates are in geometrical progression, while the corresponding abscissas are in arithmetical progression; so that the abscissas are the logarithms of the corresponding ordinates. Hence the curve may be constructed in the following manner. Fig. 3. Plate XI. *Analysis*.

Upon any right line as an axis, take the equal parts AB, BC, CD, &c. or the arithmetical progression AB, AC, AD, &c. and at the points A, B, C, D, &c. erect the perpendicular ordinates AP, BQ, CR, DS, &c. in a geometrical progression, and the curve line drawn through the extremities of these ordinates P, Q, R, S, &c. is the logarithmic or logistic curve, its abscissas AB, AC, AD, being as the logarithms of the respective corresponding ordinates BQ, CR, DS, &c.

Hence, if any abscissa AN = x , its ordinate NO = y , AP = 1, and a = a certain constant quantity, or the modulus of the logarithms, then the equation of the curve is $x = a \times \log. y = \log. y^a$; the fluxion of which being

taken, it will be $\dot{x} = \frac{a\dot{y}}{y}$; whence the following proportion,

$$y : \dot{x} :: y : a;$$

but in any curve $y : \dot{x} :: y$ the subtangent AT, and therefore the subtangent to this curve, is every where equal to the same constant quantity a , the modulus of the logarithms.

To find the area contained between any two ordinates.—Here

latter definitions. According to the first; if unity be made the common consequent of all ratios, or the common standard to which all other numbers are to be referred, then every logarithm will be the numeral exponent of the ratio of its natural number to unity. *E.g.* the ratio of 81 to 1 contains the four following ratios, *viz.* that of 81 to 27, 27 to 9, 9 to 3, and 3 to 1, or $\frac{81}{1} = \frac{81}{27} \times \frac{27}{9} \times \frac{9}{3} \times \frac{3}{1}$; but all these ratios are equal to one another, and $\frac{81}{1} = \frac{3}{1} \times \frac{3}{1} \times \frac{3}{1} \times \frac{3}{1} = \left(\frac{3}{1}\right)^4$; consequently the logarithm of 81, is four times as great as that of 3. In the same manner, the ratio of 24 to 1, or $\frac{24}{1} = \frac{24}{4} \times \frac{4}{2} \times \frac{2}{1} = \frac{3}{1} \times \frac{2}{1} \times \frac{2}{1}$; and, therefore, the logarithm of 24 is equal to the sum of the logarithms of 2, 3, and 4. And, universally, the magnitude of the ratio of A to 1, is to the magnitude of the ratio of B to 1, as the logarithm of A to the logarithm of B. Hence we derive a method of measuring all ratios whatever, let their consequents be what they will: *e.g.* the ratio of A to B is the excess of the ratio of A to 1, above the ratio of B to 1; therefore the numeral exponent of the ratio of A to B, will be the excess of the numeral exponent of the ratio of A to 1, above the numeral exponent of the ratio of B to 1, that is, the excess of the logarithm of A above the logarithm of B: therefore the magnitude of the ratio of A to B is to the magnitude of the ratio of C to D as the excess of the logarithm of A above the logarithm of B, which is the measure of the former ratio, is to the excess of the logarithm of C above that of D, which is the measure of the latter ratio: and thus we see that logarithms are as true and proper measures of ratios, as circular arcs are of angles.

The nature and genius of logarithms will be easily conceived from what follows:—A series of quantities increasing or decreasing according to the same ratio is called a *geometrical progression*; e. gr. 1. 2. 4. 8. 16. 32, &c. A series of quantities increasing, or decreasing, according to the same difference, is called an *arithmetical progression*; e. gr. 3. 6. 9. 12. 15. 18. 21. Now, if under the numbers proceeding in a geometrical ratio, be placed as many of those proceeding in the arithmetical one, these last are called the *logarithms* of the first.

Suppose e. gr. two progressions :

Geomet. 1. 2. 4. 8. 16. 32. 64. 128. 256. 512.

Arithmet.	0.	1.	2.	3.	4.	5.	6.	7.	8.	9.
-----------	----	----	----	----	----	----	----	----	----	----

Logarithms.

0 will be the logarithm of the first term; viz. 1; 5, of the 6th, 32; 7, the logarithm of the 8th, 128, &c.

These indices or logarithms may be adapted to any geometric series; and, therefore, there may be as many kinds of indices or logarithms, as there can be taken kinds of geometric series; but the logarithms most convenient for common use, are those adapted to a geometrical series increasing in a ten-fold progression, as in the sequel. The doctrine and use of logarithms may be conceived from the following propositions.

1. If the logarithm of unity be 0, the logarithm of the *factum* or product will be equal to the sum of the logarithms of the *factors*.—For as unity is to one of the factors, so is the other factor to the product. So that the logarithm of the product is a fourth equidifferent term to the logarithm of unity, and those of the factors; but the logarithm of unity being 0, the sum of the logarithms of the factors must be the logarithm of the factum, or product. Q. E. D. Hence, since the factors of a square are equal to each other, *i. e.* a square is the factum or product of its root multiplied into itself, the logarithm of the square will be double the logarithm of the root.

We will consider these numbers under each of the two

LOGARITHMS.

In the same manner it appears, that the logarithm of the cube is triple; of the biquadrate, quadruple; of the fifth power, quintuple; of the sixth, sextuple, &c. of the logarithm of the root.

Unity, therefore, is to the exponent of the power, as the logarithm of the root to the logarithm of the power.

So that the logarithm of the power is had, if the logarithm of the root be multiplied by its exponent; and the logarithm of the root is had, if the logarithm of the power be divided by its exponent.

And hence we derive one of the great uses of logarithms, which is to expedite and facilitate the business of multiplication, involution of powers, and extraction of roots; the former of which is here performed by mere addition, and the two latter by multiplication and division. Thus 3, the sum of the logarithms 1 and 2, is the logarithm of 8, the product of 2 and 4. In like manner 7, the sum of the logarithms 2 and 5, is the logarithm of 128, the product of 4 and 32. Again, 6, the logarithm of 64, which is the third power of 4, or 4^3 , is equal to 3×2 . And 8, the logarithm of 256, which is the fourth power of 4, or 4^4 , is equal to 4×2 . Moreover, 3, the logarithm of the square root 8, is half the logarithm 6, of the square 64; and 2, the logarithm of the cube root 4, is one-third the logarithm 6 of the cube 64.

2. *If the logarithm of unity be 0, the logarithm of the quotient will be equal to the difference of the logarithms of the divisor and dividend.*—For as the divisor is to the dividend, so is unity to the quotient; therefore the logarithm of the quotient is a fourth equidifferent number to the logarithms of the divisor, the dividend, and the logarithm of unity. The logarithm of unity, therefore, being 0, the difference of the logarithm of the divisor, and that of the dividend, is the logarithm of the quotient. Q. E. D.

Hence appears another great advantage of logarithms; viz. their expediting the business of division, and performing it by a bare subtraction. *E. gr.* 2, the difference between 7 and 5, is the logarithm of the quotient 4, obtained by dividing 128 by 32. In like manner, 5, the difference between 8 and 3, is the logarithm of the quotient 32, obtained by dividing 256 by 8.

These properties of logarithms, however, are more obvious according to our latter definition. For in that case, if $r^a = a$, and $r^b = b$, x and y being the logarithms of a and b , we have immediately from the first principles of algebra,

$$r^x \times r^y = r^{x+y} = ab \quad \text{Multiplication.}$$

$$r^x \div r^y = r^{x-y} = \frac{a}{b} \quad \text{Division.}$$

$$(r^x)^n = r^{x \cdot n} = r^{x^n} = a^n \quad \text{Involution.}$$

$$\sqrt[n]{r^x} = r^{x/n} = r^{x^{\frac{1}{n}}} = \sqrt[n]{a} \quad \text{Evolution.}$$

From which formulæ it is evident, that the logarithm of the product of a multiplied by b is equal to the sum of the logarithms of a and b . The logarithm of the quotient of a divided by b , is equal to the difference of the logarithms of a and b . The logarithm of the n th power of a is equal to n times the logarithm of a . And the logarithm of the n th root of a , is equal to the logarithm of a divided by n . Therefore, universally, to multiply two numbers together, we must take the sum of their logarithms: to divide one number by another, we subtract the logarithm of the latter from the logarithm of the former. To involve a number to any power, we must multiply its logarithm by the index of the power. And to extract the root of any number, we must divide its logarithm by the

index of the power of which the root is to be found. But each of these rules will require a more particular illustration, which will be found in the subsequent part of this article.

The properties of logarithms hitherto mentioned, and their various uses, are taken notice of by Stifelius; but they come all far short of the use of logarithms in trigonometry, first discovered by John Napier, baron of Merchiston, in Scotland, and first published at Edinburgh in 1614, in his *Mirifici Logarithmorum Canonis Descriptio*. This work was translated by Mr. Edward Wright, and published by him for, with the assistance of Mr. Briggs, in the year 1616 or 1618. The method of constructing the table was reserved by the ingenious author, till the sense of the learned upon his invention should be known; nevertheless Kepler, in his *Chilias Logarithmorum ad totidem Numeros rotundos*, published at Marburg in 1724; Spéidell in his *New Logarithms*, published in 1619, and republished with considerable additions, in a sixth impression in 1624; Benj. Urfinus, in his *Table of Logarithms*, printed at Cologne in 1625, and others, at home and abroad, laboured at the computation of logarithms, and constructed small tables, conformable to the plan of lord Napier. But of all those who assisted in the construction of logarithmic tables, Briggs is most conspicuous; it was he who first suggested our present system, and laboured more than any one in the computation of the numbers it contains. In the present state of analysis many comparatively short and easy methods may be employed for this purpose, that were unknown to the early writers; and for want of which the labour attending the first computation was exceedingly great; some idea of which may be formed from the following illustration.

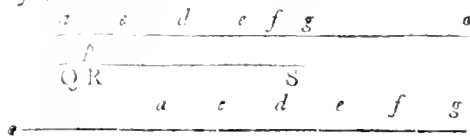

To find the logarithm of any number, according to Briggs's method.—1. Because, 1. 10. 100. 1000. 10000, &c. constitute a geometrical progression, their logarithms may be taken at pleasure: to be able, then, to express the logarithms of the intermediate numbers by decimal fractions, take 0.00000000, 1.00000000, 2.00000000, 3.00000000, 4.00000000, &c. 2. It is manifest, that for those numbers which are not contained in the scale of geometrical progression, the just logarithms cannot be had: yet they may be had so near the truth, that, as to matters of use, they shall be altogether as good as if strictly just. To make this appear, suppose the logarithm of the number 9 were required; between 1.00000000 and 10.00000000, find a mean proportional, and between their logarithms 0.00000000, and 1.00000000 an equidifferent mean, which will be the logarithm thereof; that is, of a number exceeding three by $\frac{1}{100000000}$, and therefore far remote from nine. Between 3 and 10, therefore, find another mean proportional, which may come somewhat nearer 9; and between 10 and this mean another still; and so on between the numbers next greater and next less than 9, till at last you arrive at $9 \frac{1}{100000000}$; which not being one millionth part from 9, its logarithm may, without any sensible error, be taken for that of 9 itself. Seeking then in each case for the logarithms of the mean proportionals, you will at last have 0.954251, which is exceedingly near the true logarithm of 9. 3. If in like manner you find mean proportionals between 1.00000000 and 3.1622777, and align the proper logarithms to each, you will at length have the logarithm of the number 2, and so of the rest.

Such was the method employed by the early computers of logarithms: and though they had certain means of abridging the operations in particular cases, yet it is evident that the computation of them was not effected without immense labour; a particular and interesting account of which, with an explanation of the several modifications of the

LOGARITHMS.

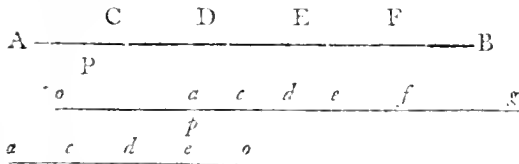

the above method made use of by different authors, may be seen in the introduction to Dr. Hutton's Mathematical Tables. It is unnecessary to observe, that these computations were only required for prime numbers; for these being once obtained, the logarithms of all other numbers were found by simple addition. At present, we have only spoken of logarithms as they are applicable to numerical computations. But they are also of very extensive use in the higher geometry, particularly in the doctrine of fluxions, and it will not be amiss, before we quit this part of the subject, to give an idea of the way in which they have been considered by writers on the latter science. Maclaurin, in his *Theoria Fluxionum*, has explained the nature and general properties of logarithms, agreeably to the notion of their first inventor, Lord Napier, delivered in his *Mirif. Logar. Canon*. He there supposes logarithms, and the quantities to which they correspond, to be generated by the motion of a point. If this point moves over equal spaces in equal times, the line described by it increases equally.

Again, when it decreases proportionally when the point that moves, or it describes such parts in equal times as are always in the same constant ratio to the lines from which they are subtracted, or to the distances of that point at the beginning of those times, from a given term in the line. In like manner, a line may increase proportionally, if in equal time the moving point describes spaces proportional to its distances from a certain term, at the beginning of each time. Thus, in the first case, let ac be to ao , cd to co , de to do , ef to fo

eo , fg to fo , always in the same ratio of QR to QS ; and suppose that the point p sets out from a , describing ac, cd, de, ef, fg , in equal parts of the time; and let the space described by p , in any given time, be always in the same ratio to the distance of p from o , at the beginning of that time, then will the right line ao decrease proportionally; and the lines ao, co, do, eo, fo , &c. or the distances of the point p from o , at equal succeeding intervals of time, are in a continued geometrical progression.

In like manner, the line oa increases proportionally, if the point p in equal times describes spaces ac, cd, de, ef, fg , &c. so that ac is to ao , cd to co , de to do , &c. in a constant ratio.

If we now suppose a point P describing the line AB with an uniform motion, equal to that with which p sets out from a , in describing the line ao , while the point p describes a line increasing or decreasing proportionally, the line AP described by P with this uniform motion, in the same time that oa by increasing or decreasing proportionally, becomes equal to op , is the logarithm of op . Thus AC, AD, AE , &c. are the logarithms of oc, od, oe , &c. respectively; and oa is the quantity whose logarithm is supposed equal to nothing.

We have here abstracted from numbers, that the doctrine

may be the more general; but it is plain, that if AC, AD, AE , &c. be supposed 1, 2, 3, &c. in arithmetic progression; oc, od, oe , &c. will be in geometric progression; and that the logarithm of oa , which may be taken for unity, is nothing.

Lord Napier, in his first scheme of logarithms, supposes, that while op increases or decreases proportionally, the uniform motion of the point P , by which the logarithm of op is generated, is equal to the velocity of p at a ; that is, at the term of time when the logarithms begin to be generated. Hence logarithms, formed after this model, are called *Napier's logarithms*, and sometimes *natural logarithms*.

When the ratio is given, the point p describes the difference of the terms of the ratio in the same time. When a ratio is duplicate of another ratio, the point p describes a difference of the terms in a double time. When a ratio is triplicate of another, it describes the difference of the terms in a triple time; and so on. Also, when a ratio is compounded of two or more ratios, the point p describes the difference of the terms of that ratio, in a time equal to the sum of the times in which it describes the differences of the terms of the simple ratios of which it is compounded. And what is here said of the times of the motion of p , when op increases proportionally, is to be applied to the spaces described by P in those times, with its uniform motion.

Hence the chief properties of logarithms are deduced. They are the measures of ratios. The excess of the logarithm of the antecedent above the logarithm of the consequent measures the ratio of those terms. The measure of the ratio of a greater quantity to a lesser is positive, as this ratio compounded with any other ratio increases it. The ratio of equality, compounded with any other ratio, neither increases nor diminishes it; and its measure is nothing. The measure of the ratio of a lesser quantity to a greater is negative, as this ratio compounded with any other ratio diminishes it. The ratio of any quantity A to unity, compounded with the ratio of unity to A , produces the ratio of A to A , or the ratio of equality; and the measures of those two ratios destroy each other, when added together: so that when the one is considered as positive, the other is to be considered as negative.

When op increases proportionally, the motion of p is perpetually accelerated; and, on the contrary, when op decreases proportionally, the motion of p is perpetually retarded.

If the velocity of the point p be always as the distance op , then will this line increase or decrease in the manner supposed by Lord Napier: and the velocity of the point p being the fluxion of the line op , will always vary in the same ratio as this quantity itself. See Maclaurin's *Flux.* art. 151—160.

The fluxion of any quantity is to the fluxion of its logarithm, as the quantity itself is to unity.

Hence the fluxion of the logarithm of x will be $\frac{\dot{x}}{x}$.

For $x : 1 :: \dot{x} : \frac{\dot{x}}{x}$ = the fluxion of the logarithm required.

When op increases proportionally, the increments generated in any equal times, are accurately in the same ratio as the velocities of p , or the fluxions of op , at the beginning, end, or at any similar terms of those times.

When op increases, or decreases proportionally, the fluxions of this line, in all the higher orders, increase or decrease in the same proportion as the line itself increases or decreases; so that one rule serves for comparing together those of any kind at different terms of time; and in this case we never

arrive at any constant or invariable fluxion. If the logarithms of two quantities be always to each other in any invariable ratio, the fluxions of those quantities shall be in a ratio that is compounded of a ratio of the quantities themselves, and of the invariable ratio of their logarithms.

Let op be greater than oa ; $ad:ap::oa:op$; and let oa ,

$$\frac{o}{A} \frac{q}{P} \frac{a}{P} \frac{d}{P} \frac{e}{P} \frac{f}{P} \frac{g}{P} \frac{h}{P} \frac{k}{P} \frac{p}{P} \frac{x}{P}$$

$ad, de, ef, fg, \&c.$ be in continued proportion: then by adding together $ad, \frac{1}{2}de, \frac{1}{3}ef, \frac{1}{4}fg, \&c.$ we approximate continually to the value of AP , the logarithm of op . And we approximate continually to the logarithm of od , by summing up the differences betwixt ad and $\frac{1}{2}de, \frac{1}{3}ef, \&c.$ and $\frac{1}{2}fg, \frac{1}{3}gb$ and $\frac{1}{6}bk, \&c.$ See Maclaurin's Fluxions, art. 171, 172. From what has been said, it follows, that if $ao:od::op:ox$, then the logarithm of ox will be equal to the sum of the logarithms of op and od : that is, to the sum of $ad + \frac{1}{2}de + \frac{1}{3}ef + \frac{1}{4}fg + \frac{1}{5}gh + \frac{1}{6}hk, \&c.$ and $ad + \frac{1}{2}de + \frac{1}{3}ef + \frac{1}{4}fg + \frac{1}{5}gb + \frac{1}{6}bk, \&c.$ and $ad + \frac{1}{2}de + \frac{1}{3}ef + \frac{1}{4}fg + \frac{1}{5}gb + \frac{1}{6}bk, \&c.$ which sum is $2ad + \frac{2}{3}ef + \frac{2}{5}gb, \&c.$

Let $aq = ad$; then the logarithm of ox will measure the ratio of od to oq . But od and oq have half their sum equal to oa , and half their difference equal to ad , which are the two first terms of the geometric progression $oa, ad, de, ef, fg, gb, bk, \&c.$ Hence, if $oa = 1$, and $ad = x$, $de, ef, fg, \&c.$ will be respectively, $x^2, x^3, x^4, \&c.$ and the ratio of $1+x$ to $1-x$ will be equal to that of od to oq . But the logarithm of this ratio is $2ad + \frac{2}{3}ef + \frac{2}{5}gb$

$+$, $\&c.$ therefore the logarithm of $\frac{1+x}{1-x} = 2 \times x + \frac{2}{3}x^3 + \frac{1}{5}x^5 + \frac{1}{7}x^7 + \&c.$ agreeably to what has been shewn by Dr. Halley and others.

Having thus given an idea of the forms under which logarithms were considered, and the methods by which they were computed by some of the early writers on this subject, it will be proper now to bestow a few columns, to explain the more modern way of investigating the principles and of computing these very useful numbers; in doing which, however, the limits of our article will necessarily confine our observation to only the most popular and useful formulae.

We have already defined a logarithm to be the index of a certain number called the radix, which being raised to the power denoted by that index or logarithm, will produce the given number. If, therefore, $r^x = N$, then x is the logarithm of N , and r is the radix of the system. Now, first, in order to find an analytical expression for N in terms of x and r ; r^x must be converted into a series, for which purpose it may be put under the form

$$r^x = (1 + (r-1))^x = 1 + x(r-1) + \frac{x \cdot (x-1)}{1 \cdot 2} (r-1)^2 + \frac{x \cdot (x-1) \cdot (x-2)}{1 \cdot 2 \cdot 3} (r-1)^3 + \&c.$$

$$= 1 + x \left\{ (r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{6}(r-1)^3 - \&c. \right\}$$

$$+ \frac{x^2}{1 \cdot 2} \left\{ (r-1)^2 - (r-1)^3 + \&c. \right\} =$$

$$1 + Ax + A'x^2 + A''x^3 + \&c.$$

by writing

$$A = (r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{6}(r-1)^3 - \&c.$$

$$A' = (r-1)^2 - (r-1)^3 + \&c.$$

$$A'' = \&c.$$

where $A, A', A'', \&c.$ are constant but unknown quantities. And now, in order to determine the law by which they are connected with each other, let x be increased by any indeterminate quantity z ; then $r^{x+z} = 1 + A(x+z) + A'(x+z)^2 + A''(x+z)^3 + \&c. \dots A^{(n-1)}(x+z)^{n-1}$; or, expanding the powers of $x+z$, and stopping at the first two terms, we have

$$r^{x+z} = 1 + A(x+z) + A'(x^2 + 2xz + \&c.) + A''(x^3 + 3x^2z + \&c.) + A^{(n-1)}(x^n + nx^{n-1}z + \&c.) + A^{(n)}(x^{n+1} + (n+1)x^n z + \&c.)$$

Again

$$r^{x+z} = r^x \times r^z = (1 + Ax + A'x^2 + A''x^3 + \&c.) \times (1 + Az + A'z^2 + A''z^3 + \&c.)$$

the actual multiplication of which gives

$$r^{x+z} = 1 + A(x+z) + A'x^2 + A''x^3 \dots A^{(n-1)}x^n + A^2xz + A'A'x^2z \dots \&c.$$

whence, by comparing the corresponding terms in the two expansions, we have

$$2A' = A^2, \text{ or } A' = \frac{A^2}{2}; \quad 3A'' = A'A' = \frac{A^3}{2};$$

and therefore $A'' = \frac{A^3}{1 \cdot 2 \cdot 3}$

in the same way $A''' = \frac{A^4}{1 \cdot 2 \cdot 3 \cdot 4}$

and generally $A^{(n-1)} = \frac{A^n}{1 \cdot 2 \cdot 3 \dots n}$

$$A^n = \frac{A^{n+1}}{1 \cdot 2 \cdot 3 \dots (n+1)}$$

And consequently,

$$r^x = N = 1 + Ax + \frac{A^2}{1 \cdot 2} x^2 + \frac{A^3}{1 \cdot 2 \cdot 3} x^3 + \&c.$$

which is the analytical expression for any number in terms of the radix r and its logarithm x ; but the reverse of this, by which the logarithm is expressed in terms of its number and radix, is the formula which is more particularly applicable in the present enquiry. This may be found as follows.

In the preceding article we found

$$r^x = N = 1 + Ax + \frac{A^2}{1 \cdot 2} x^2 + \frac{A^3}{1 \cdot 2 \cdot 3} x^3 + \&c.$$

where $A = (r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{6}(r-1)^3 - \&c.$; and if now we make

$$B = (N-1) - \frac{1}{2}(N-1)^2 + \frac{1}{6}(N-1)^3 - \&c.$$

we shall have on the same principles

$$N^z = 1 + Bz + \frac{B^2}{1 \cdot 2} z^2 + \frac{B^3}{1 \cdot 2 \cdot 3} z^3 + \&c.$$

But

$$N^z = r^{xz} = 1 + Axz + \frac{A^2}{1 \cdot 2} x^2 z^2 + \frac{A^3}{1 \cdot 2 \cdot 3} x^3 z^3 +$$

$\&c.$; whence, by comparing the co-efficients of z in both series, we have

LOGARITHMS.

$$A x = B; \frac{A^2 x^2}{1 \cdot 2} = \frac{B^2}{1 \cdot 2}; \frac{A^3 x^3}{1 \cdot 2 \cdot 3} = \frac{B^3}{1 \cdot 2 \cdot 3} \&c;$$

each of which gives the same result, viz. $A x = B$; whence we obtain immediately

$$x = \frac{B}{A} = \frac{(N-1) - \frac{1}{2}(N-1)^2 + \frac{1}{3}(N-1)^3 - \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \&c.}$$

which is the analytical expression for the logarithm of any number N , in functions of itself, and the radix of the system; that is, writing a instead of N

$$\log. a = \frac{(a-1) - \frac{1}{2}(a-1)^2 + \frac{1}{3}(a-1)^3 - \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \&c.}$$

$$\text{Or, } \log. 1 \pm a = \frac{\pm a - \frac{1}{2}a^2 \pm \frac{1}{3}a^3 - \frac{1}{4}a^4 \pm \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \&c.}$$

This, however, must only be considered as a simple algebraical method of expressing a logarithm; but it does not always answer the purposes of calculation, for if a be any number greater than unity, it is obvious that the series in the numerator will either converge very slowly, or otherwise will diverge, and the same with regard to the denominator, supposing r to be equal to 10, as it is in the common system; in fact, the terms of the series are larger the more remote they are from the beginning; and consequently no number of them can exhibit, either exactly or nearly, the true sum. Let us, therefore, investigate the method of submitting these to calculation; in order to which we will repeat again our last series, viz.

$$\log. 1 \pm a = \frac{\pm a - \frac{1}{2}a^2 \pm \frac{1}{3}a^3 - \frac{1}{4}a^4 \pm \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \&c.}$$

and here, since the denominator is always a constant quantity when the radix of the system is given, we may make

$$M = (r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \&c.$$

which renders the above expression still more simple, as in that case it becomes barely

$$\log. 1 + a = \frac{1}{M} \times \left\{ a - \frac{1}{2}a^2 + \frac{1}{3}a^3 - \frac{1}{4}a^4 + \&c. \right\}$$

Or, taking a negative,

$$\log. 1 - a = \frac{1}{M} \times \left\{ -a - \frac{1}{2}a^2 - \frac{1}{3}a^3 - \frac{1}{4}a^4 - \&c. \right\}$$

Whence again by subtraction,

$$\log. \left(\frac{1+a}{1-a} \right) = \frac{2}{M} \left\{ a + \frac{1}{3}a^3 + \frac{1}{5}a^5 + \frac{1}{7}a^7 + \&c. \right\}$$

$$\text{Now } a = \frac{1 + \frac{a-1}{a+1}}{1 - \frac{a-1}{a+1}}; \text{ if, therefore, we substitute in the}$$

foregoing expression $\frac{a-1}{a+1}$ instead of a , it becomes

$$\log. a = \frac{2}{M} \times \left\{ \left(\frac{a-1}{a+1} \right) + \frac{1}{3} \left(\frac{a-1}{a+1} \right)^3 + \frac{1}{5} \left(\frac{a-1}{a+1} \right)^5 + \&c. \right\}$$

which series must necessarily converge, because the denominator of each of the fractions is greater than its numerator; still, however, when a is a number of any considerable magnitude, the decrease in the terms will be so slow as to render the formula useless for the purposes of calculation.

At present we have assumed the series which constitutes the denominator in our first expression a known quantity,

which we have represented by M . It will, however, be proper, before we proceed any farther, to offer a few remarks upon the absolute value of this series, according to any given radix. First then, since

$$\log. 1 + a = \frac{a - \frac{1}{2}a^2 + \frac{1}{3}a^3 - \frac{1}{4}a^4 + \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \&c.}$$

the denominator and numerator of this fraction are totally independent of each other, and therefore r may be assumed at pleasure, and the value of the whole denominator computed for any particular magnitude assigned to this letter: or otherwise, the whole denominator may be taken equal to any quantity, and the value of r itself determined by computation. The latter method, at first sight, appears the most eligible; for by assuming the whole denominator equal to unity, it disappears entirely, and the expression becomes

$$\log. (1 + a) = a - \frac{1}{2}a^2 + \frac{1}{3}a^3 - \frac{1}{4}a^4 + \&c.$$

There are, however, inconveniences attending this system, that do not appear upon a slight view of the subject, but which are notwithstanding very evident upon a farther investigation. In the case in which the whole denominator is assumed equal to unity, the value of r , the radix of this particular system, is found to be 2.7182818284, &c. and the

fraction $\frac{1}{M}$ becomes = 1. These constitute what are called

hyperbolic logarithms, and which are treated of under that article in the present work. We shall, therefore, enter no farther upon the subject in this place, than is necessary to shew the defect of this system for general purposes, when compared with that now in common use, a defect which is by no means compensated by the trifling advantage attending their computation. In the common system the radix r is assumed equal to 10, the same as the radix of our scale of notation; and hence arises a most important advantage, which is, that the logarithm of all numbers expressed by the same digits, whether integers, decimals, or mixed of the two, have the same decimal part; the only alteration being in the index or characteristic of the logarithm. For the radix being 10, 0, 1, 2, 3, &c. will be logarithms of 1, 10, 10², &c. that is, 10⁰ = 1, 10¹ = 10, 10² = 100, &c.; and therefore, to multiply or divide a number by any power of 10, we have only to add or subtract the number expressing that power from the integral part of the logarithm, and the decimal part will still remain the same, by which means the tables of logarithms are much more contracted than they could be with any other radix; for in the hyperbolic system, or in any other, which has not its radix the same as that of the scale of notation, every particular number would require a particular logarithm; and this circumstance would either swell the tables to an unmanageable size, or if they were kept within the present limits, frequent computations would become necessary; so that in either way it is clear that the advantages of the present logarithms much more than counterbalance the extra trouble in computing them. This in fact only consists in multiplying the hyperbolic logarithm by a constant factor; viz. the reciprocal of the foregoing constant denominator represented above by $\frac{1}{M}$, the value of

$$\text{which, when } r = 10, \text{ is } \frac{1}{2.30258509, \&c.} = .43429448,$$

&c. Hence it is obvious, that different systems of logarithms are connected together by constant multipliers, and by means of which a logarithm may always be converted from one scale to another. Thus the hyperbolic logarithm of a
1.1 2 number

LOGARITHMS.

number is transformed to the common logarithm, by multiplying the former by .4342944; and the latter is converted into the former by multiplying it by 2.30258509.

Having said thus much with regard to advantages of different systems of logarithms, and the method of transform-

ing them from one scale to another; we will now add one example by way of illustration. Let it therefore be proposed to find the common logarithm of 3. In this case our

$$\text{series } \log. a = \frac{2}{M} \times \left\{ \left(\frac{a-1}{a+1} \right) + \frac{1}{3} \left(\frac{a-1}{a+1} \right)^3 + \frac{1}{5} \left(\frac{a-1}{a+1} \right)^5 + \&c. \right\}$$

$$\text{becomes } \log. 3 = \frac{2}{M} \times \left\{ \frac{1}{2} + \frac{1}{3 \cdot 2^3} + \frac{1}{5 \cdot 2^5} + \frac{1}{7 \cdot 2^7} + \&c. \right\}$$

the computation of which will stand thus:

$$\begin{array}{rcl} \frac{1}{2} & = & .5 \\ \frac{1}{3 \cdot 2^3} & = & .041666666 \\ \frac{1}{5 \cdot 2^5} & = & .00625 \\ \frac{1}{7 \cdot 2^7} & = & .0011160714 \\ \frac{1}{9 \cdot 2^9} & = & .0002170138 \\ \frac{1}{11 \cdot 2^{11}} & = & .0000443892 \\ \frac{1}{13 \cdot 2^{13}} & = & .0000093900 \\ \frac{1}{15 \cdot 2^{15}} & = & .0000020345 \\ \frac{1}{17 \cdot 2^{17}} & = & .0000004487 \end{array}$$

$$\frac{1}{19 \cdot 2^{19}} = .000000100,$$

$$\frac{1}{21 \cdot 2^{21}} = .0000000227$$

$$\frac{1}{23 \cdot 2^{23}} = .0000000050$$

whence $\frac{2}{2.30258509}$, or $43429448 \times 5493061422 = .4771212$, which is the logarithm of 3 required.

This series, we have already observed, will only answer for the computation of the logarithms of small numbers, in other cases different series must be employed according to the particular number under consideration. The limits of this article will not admit of an investigation of the separate cases. But for the sake of reference it will be useful to subjoin a few of the most useful formulæ, for which purpose we avail ourselves of the selection made by Mr. Bencey, in his valuable treatise of Trigonometry.

1. $\log. a = \frac{1}{M} \times \left\{ (a-1) - \frac{1}{2} (a-1)^2 + \frac{1}{3} (a-1)^3 - \&c. \right\}$
2. $\log. a = \frac{1}{M} \times \left\{ \left(\frac{a-1}{a} \right) + \frac{1}{2} \left(\frac{a-1}{a} \right)^2 + \frac{1}{3} \left(\frac{a-1}{a} \right)^3 - \&c. \right\}$
3. $\log. a = \frac{2}{M} \times \left\{ \left(\frac{a-1}{a+1} \right) + \frac{1}{3} \left(\frac{a-1}{a+1} \right)^3 + \frac{1}{5} \left(\frac{a-1}{a+1} \right)^5 + \&c. \right\}$
4. $\log. \frac{a}{b} = \frac{1}{M} \times \left\{ \left(\frac{a \div b}{b} \right) - \frac{1}{2} \left(\frac{a \div b}{b} \right)^2 + \frac{1}{3} \left(\frac{a \div b}{b} \right)^3 - \&c. \right\}$
5. $\log. \frac{a}{b} = \frac{1}{M} \times \left\{ \left(\frac{a \div b}{a} \right) + \frac{1}{2} \left(\frac{a \div b}{a} \right)^2 + \frac{1}{3} \left(\frac{a \div b}{a} \right)^3 - \&c. \right\}$
6. $\log. \frac{a}{b} = \frac{2}{M} \times \left\{ \left(\frac{a \div b}{a+b} \right) + \frac{1}{3} \left(\frac{a \div b}{a+b} \right)^3 + \frac{1}{5} \left(\frac{a \div b}{a+b} \right)^5 + \&c. \right\}$
7. $\log. a = \log. (a-1) + \frac{1}{M} \times \left\{ \frac{1}{a} + \frac{1}{2a^2} + \frac{1}{3a^3} + \frac{1}{4a^4} + \&c. \right\}$
8. $\log. a = \log. (a-1) + \frac{1}{M} \times \left\{ \frac{1}{a-1} - \frac{1}{2(a-1)^2} + \frac{1}{3(a-1)^3} - \&c. \right\}$
9. $\log. a = \log. (a-2) + \frac{2}{M} \times \left\{ \frac{1}{a-1} + \frac{1}{3(a-1)^3} + \frac{1}{5(a-1)^5} + \&c. \right\}$

To the above may be added the following, which will be found useful on many occasions.

10. $\log. a = \frac{1}{M} \times \left\{ (a - a^{-1}) - \frac{1}{2} (a^2 - a^{-2}) + \frac{1}{3} (a^3 - a^{-3}) - \&c. \right\}$
11. $\log. (a+z) = \log. a + \frac{1}{M} \times \left\{ \frac{z}{a} - \frac{1}{2} \frac{z^2}{a^2} + \frac{1}{3} \frac{z^3}{a^3} - \frac{1}{4} \frac{z^4}{a^4} + \&c. \right\}$
12. $\log. (a-z) = \log. a - \frac{1}{M} \times \left\{ \frac{z}{a} + \frac{1}{2} \frac{z^2}{a^2} + \frac{1}{3} \frac{z^3}{a^3} + \frac{1}{4} \frac{z^4}{a^4} + \&c. \right\}$
13. $\log. (a \pm z) = \log. a \pm \frac{2}{M} \times \left\{ \left(\frac{z}{a+z} \right) + \frac{1}{3} \left(\frac{z}{a+z} \right)^3 + \frac{1}{5} \left(\frac{z}{a+z} \right)^5 + \&c. \right\}$
14. $\log. a = \frac{m}{M} \times \left\{ (\sqrt[m]{a} - 1) - \frac{1}{2} (\sqrt[m]{a} - 1)^2 + \frac{1}{3} (\sqrt[m]{a} - 1)^3 - \&c. \right\}$

LOGARITHMS.

These formulæ might have been extended to a much greater length, but those that are given will be found to embrace the generality of cases, and will be found useful on various occasions.

The publications on the subject of logarithms have been so numerous, that we can only find room to mention a small portion of them, but as it is useful to know which are reputed the best, and particularly the best editions of the same authors, we shall subjoin the following enumeration, which may be considered as containing the most respectable and accurate works of this kind.

1. The first canon of logarithms for natural numbers from 1 to 10,000, and from 90,000 to 100,000, was constructed and published in 1622, by Briggs, with the approbation of the inventor lord Napier.

2. Briggs's logarithms, with their difference to 10 places of figures; as also the logarithmic sines, tangents, &c. by George Miller, London 1631.

3. "Trigonometria," by Richard Norwood 1631, containing a table of logarithms from 1 to 10,000, besides sines, tangents, &c.

4. "Directorium Generale Uranometricum," by Francis Bonaventura Cavalieri, Bologna 1632. This work, beside the usual table of logarithms, contains several new and useful tables of sines, versed sines, &c. and some other original matter.

5. In 1643 appeared the "Trigonometria" of the same author, which may also be considered an interesting work.

6. "Tabule Logarithmicæ" by Nathaniel Rowe, London 1633. In this work the logarithms are given to eight places of figures, for every number from 1 to 100,000, and logarithmic sines, tangents, &c. to every hundredth part of degrees to ten places.

7. "Trigonometria Britannica" by John Newton, London 1658. Here the logarithmic tables are put in the most convenient form, being nearly the same as is now adopted by authors of the present period.

8. Adrian Vlacq also published different editions of logarithmic tables, which have been since republished; these are generally considered very accurate and useful tables, particularly the edition of 1631.

9. Sherwin's mathematical tables, published in 8vo. London 1706, form the most complete collection of any we have yet noticed; containing, besides the logarithms of all numbers from 1 to 100,000, the sines, tangents, secants, and versed sines, both natural and logarithmic, to every minute of the quadrant. The first edition was printed in 1706, but the third, published in 1742, as revised by Gardiner, is considered as superior to any other. The fifth, and last, edition published in 1717, is so incorrect, that no dependence can be placed upon it.

The third edition above-mentioned, which is called Gardiner's tables, was republished at Avignon, in France, in

1770, but this is not considered so accurate as the original one by Gardiner himself.

10. An "Antilogarithmic Canon," for readily finding the number corresponding to any logarithm, was begun by the algebraist Harriot, and completed by Warner, the editor of the former's works, but it was never published for want of proper encouragement. But a complete canon of this kind was published by James Dodson 1742, in which the numbers answering to each logarithm from 1 to 100,000, are computed to 11 places of figures.

11. In 1723 was published, by M. Callet, at Paris, a very neat and useful collection of logarithmic tables; and in 1795 an enlarged edition of the same work, under the title of "Tables Portative de Logarithmes." This is an elegant work, beautifully printed and stereotyped, at the celebrated Didot's press; it is more correct than the former edition, though it contains a few errors not noticed in the list of errata.

12. Dr. Hutton's "Mathematical Tables," containing the common hyperbolic and logistic logarithms, also sines, tangents, secants, and versed sines, both natural and logarithmic, together with several other tables useful in mathematical calculations. To which is prefixed a history of the discoveries and writings of the most celebrated authors on this subject. This work was first published in 1785, since which time it has passed through several editions, which are all very correct.

13. Taylor's tables of logarithmic sines and tangents to every second of the quadrant, to which is prefixed a table of logarithms from 1 to 100,000. This is a very valuable work, and has a useful introduction composed by the late astronomer royal Dr. Maskelyne.

14. Vega's tables, published in Latin and German, is also a very excellent performance, particularly the second edition of 1797.

15. Another very accurate and extensive collection of tables, computed for the decimal division of the circle by Borda, and revised and augmented by Delambre, was published in Paris. This work is held in great esteem by the French; but it is of little use to English mathematicians on account of the particular division of the circle. It is, however, preceded by a very perspicuous and scientific investigation of the most useful logarithmic series, and trigonometrical formulæ; and may therefore be read with interest by the general mathematician. Besides the authors above-mentioned, many others have treated on the subject of logarithms, among the principal of whom are Halley, Leibnitz, Mercator, Cotes, Brook Taylor, Euler, Maclaurin, Wolfius, Keil, and Simpson.

As we have frequent occasion to refer to tables of logarithms in the course of this work; we have subjoined a table of logarithms of all numbers from 1 to 10,000, which will be found useful in various cases when other tables may not be at hand.

LOGARITHMS.

TABLE of Logarithms, from 1 to 10,000.
